Low Vitamin B_{12} Concentrations in Serum in Fish Tapeworm Anæmia

VARIOUS communications have been published on the microbiological vitamin B_{12} activity in the sera from both healthy persons and patients suffering from various diseases. The concentration of vitamin B_{12} varies fairly considerably in normal people. The lower limit is 70–100 μμgm. and the upper 420–900 μμgm. vitamin B_{12}/ml. of serum, depending on the microbiological method employed. Very low values, usually less than 50 μμgm./ml., have been found in pernicious anæmia[1].

Megaloblastic anæmia in fish tapeworm (*Diphyllobothrium latum*) carriers shows a similar hæmatological picture to that of genuine pernicious anæmia. The essential factor in the origination of this anæmia would seem to be vitamin B_{12} deficiency caused by fish tapeworm which deprives the host organism of vitamin B_{12} [2]. However, there is still a lack of data on the serum vitamin B_{12} concentration in this disease. We therefore determined the microbiological activity in the serum of eight patients with fish tapeworm anæmia. Twenty convalescents who had been treated for different diseases were examined as controls.

Table 1. MICROBIOLOGICAL B_{12}-VITAMIN ACTIVITY IN SERA FROM EIGHT PATIENTS WITH FISH TAPEWORM ANÆMIA AND FROM TWENTY CONTROLS

Diagnosis	Sex	Age	Vitamin B_{12} (μμgm./ml.)
Anæmia perniciosa diphyllobothrica	♀	38	< 50
,, ,, ,,	♂	17	< 50
,, ,, ,,	♀	14	< 50
,, ,, ,,	♀	11	< 50
,, ,, ,,	♀	64	< 50
,, ,, ,,	♂	58	< 50
,, ,, ,,	♂	63	65
,, ,, ,,	♀	84	< 50
Hypertensio arterialis	♂	59	605
Cholecystitis	♂	70	428
Hernia inguinalis	♂	61	720
Anæmia perniciosa diphyllobothrica in remission induced by worm cure	♂	17	361
Apoplexia cerebri	♂	63	733
Cardiosclerosis	♀	65	320
Anæmia hypochromica	♀	63	238
Ulcus ventriculi	♂	36	583
Anæmia perniciosa in remission induced by liver extract	♂	56	420

Cardiosclerosis	♀	62	200
Cardiosclerosis	♂	69	180
Hernia diaphragmatica	♂	69	370
Nihil	♂	23	601
Cholecystopathia	♂	52	786
Arteriosclerosis universalis	♂	76	444
Diabetes mellitus	♂	57	964

Serum vitamin B_{12} activity was determined with *Lactobacillus leichmannii* 313 (*ATCC* 7830). The method employed was the same as that described in Appendix No. 1, 1955, of the Swedish Pharmacopeia. Values less than 50 μμgm./ml. cannot be measured with sufficient accuracy with this method. Table 1 summarizes the results.

It will be seen that there is a pronounced difference in the serum vitamin B_{12} activity of patients with fish tapeworm anæmia and that of the control group. Seven out of eight anæmia patients gave concentrations less than 50 μμgm./ml. A somewhat higher value, 65 μμgm. vitamin B_{12} per ml. of serum, was found in this group in one case only. The control group displayed great variations ranging from 180 to 964 μμgm. vitamin B_{12} per ml., the average being 561 μμgm. There was no overlapping between the two groups.

To obtain the variations and the mean value of the vitamin B_{12} concentrations in the serum of fish tapeworm anæmia patients requires both more comprehensive material and a more accurate method. However, this introductory investigation shows that the vitamin B_{12} serum concentrations in fish tapeworm anæmia are of the same range as those in genuine pernicious anæmia. This supports the view concerning vitamin B_{12} deficiency in *D. latum* carriers with anæmia.

Stem Canker (*Macrophomina phaseoli*) of Cotton Seedlings in the Sudan Gezira

IN some seasons cotton seedlings (*Gossypium barbadense* L.) in the irrigated Gezira area of the Sudan suffer considerable damage from stem canker caused by the fungus *Macrophomina phaseoli* (Maubl.) Ashby, also known as *Rhizoctonia bataticola* (mycelium) and *Sclerotium bataticola* (sclerotia).

First symptoms are the appearance of circular red spots up to about 5–6 mm. in diameter on the cotyledons of seedlings two or three weeks after emergence from the soil. Under favourable climatic conditions, notably high humidity, these spots spread and extend down the cotyledonary stalk to produce a conspicuous reddish-purple lesion at the cotyledonary node. These lesions become brown, dry and fibrous as dissolution of the parenchymatous cortical tissue of the young stem proceeds and eventually small black sclerotia develop. In severe cases the stem is completely girdled at the cotyledonary node, at which point affected plants tend to break (especially if handled), and thereafter die or suffer a severe check to growth. In warm dry weather cankered plants often recover and the disease dries out without causing much damage.

In the 1954–55 season, one of above-average post-sowing rainfall, stem canker was very prevalent in the central and southern Gezira and must have imposed a considerable check on early growth of the crop—a warning that this disease might become a major problem were earlier sowing of cotton introduced. With such earlier sowing the young crop would experience much heavier post-sowing rain than with present sowing in mid-August, by which date about two-thirds of the season's rain has normally fallen. Thus at the Gezira Research Farm in 1954 stem canker was severe and post-sowing rainfall was much heavier than usual—about 200 mm. as compared with long-term average of about 120 mm.

Although field observations strongly suggest that stem canker is favoured by excessively wet conditions in which the seedlings are exposed to prolonged water-logging, the method of infection is obscure. Attempts to produce the cotyledonary stage of the disease by spraying cultures of the pathogen and by other methods have so far failed, but characteristic stem lesions (from which the fungus was afterwards recovered) resulted from needle inoculation of the green cotyledonary node.

Pycnidia of *M. phaseoli* have not been observed on cotton in the Sudan and it is thought that seasonal infection originates from the soil, wherein the fungus survives the hot dry season in the form of small resistant sclerotia. Supporting this theory is the observation that soil fumigation with chloropicrin tended to increase stem canker incidence at the Gezira Research Farm in 1954–55. Plots fumigated with chloropicrin three to four weeks before sowing showed 24 per cent cankered seedlings (10 gallons/acre), 32 per cent (20 gallons/acre) and 45 per cent (40 gallons/acre) as compared with 24 per cent in unfumigated plots. Plots fumigated with 15 per cent methyl bromide showed 22·5 per cent (20 gallons/acre) and 23·5 per cent (40 gallons/acre), while 0·8 per cent formaldehyde drench using about 160 gallons of commercial formalin per acre gave 23·5 per cent cankered seedlings. The initial damage due to stem canker in the chloropicrin-treated plots was more than counterbalanced by the beneficial effects of fumigation, these plots producing more vigorous plants which finally yielded 32–48 per cent more seed cotton than the unfumigated plots, as compared with yield increases of 8–15 per cent for methyl bromide and 5 per cent for formalin. It is possible that the resistant sclerotia of *M. phaseoli* were able to withstand chloropicrin fumigation whereas soil micro-organisms lacking such resistant propagules were destroyed. Under the resultant conditions of reduced competition *M. phaseoli* flourished and incidence of stem canker increased, but this was not the case in fumigation with methyl bromide and formaldehyde.

Relevance of Palæomagnetic Studies of Jurassic Rocks to Continental Drift

THE early palæomagnetic studies have largely been confined to the northern hemisphere, where wide sampling of the geological column in Great Britain and North America has done much to establish the reality of polar wandering. Runcorn[1] has also suggested, on the basis of a comparison of the British and American results, that a westward drift of some 24° would account for the systematic difference he has found in the results.

Table 1

Region	Rocks sampled	Declination	Inclination	λ	K'	N
N. Yorks*	Middle Lias—Lower Corallian. Arenaceous sediments	N. 3·4° E	+66·9°	2·6°	87·5	36
Arizona	Kayenta Fm. (Lr Jur.)	N. 6·9° W	+43·5°	9·6°	50	6
North and South Rhodesia	Basalt lavas of Victoria Falls and Bulawayo	N. 30° W	−40·3°	4·6°	18·7	44
Tasmania	Intrusive dolerite sills	N. 35° W.	−85°	—	—	—

* Full details to be published.

The critical test of whether continental drift has occurred or not obviously lies in a study of the palæomagnetism of rocks of the same age in different continents. In this context the Jurassic period is of great importance, and it is now possible to assemble data from four continents as in Table 1 with the relevant statistics[2].

Although the arenaceous sediments of the British Jurassic are largely unsuitable for palæomagnetic work, being either too weak for measurement or unstable, there are sufficient which appear to be stable to give the results tabulated. Runcorn's rocks from Arizona fall in the same category, and his results, which are based on a few specimens, must be regarded with caution.

The Rhodesian basalt lavas were collected from the Bulawayo area and from the Victoria Falls, where fresh material was obtained from the second gorge with the aid of Dr. G. Bond. The basalts following above the Triassic Forest Sandstone are generally considered of lower Jurassic age. The position of the pole in the northern hemisphere (lying in Hudson Bay) is in latitude 61° N., longitude 76° W. Irving[3] carried out an extensive study of the intrusive dolerite sills of Tasmania. These sills, while certainly of Mesozoic age, have not been proved conclusively to be of Jurassic age. The ancient pole position, according to Irving, lay in latitude 50° N., longitude 23° W.

Thus it is clear that, while Britain in Jurassic times must be regarded as having approximately the same position as at present relative to the pole (the present pole lying within the circle of confidence of the Jurassic results), and the movement of America is not significant, it is equally clear that this is not the case in the southern hemisphere. The Rhodesian lavas indicate a movement of about 2,000 miles, and the Tasmanian results a movement of about 2,800 miles.

The inevitable conclusion is that continental drift must be accepted if the assumption of the coincidence of the axial dipole field with the rotational axis is accepted[4]. More exact dating of the time of drift and the relative positions of the continental blocks must depend on the more detailed work at present in hand in Great Britain, South Africa and Australia.

A Statistical Information Theory of Visual Thresholds

In their recent letter on this subject Gregory and Cane[1] state that "perhaps other threshold and summation phenomena may be described in terms of statistical information available in neural information channels". A survey of available data on the relationship between the Weber–Fechner fraction $\Delta I/I$ and stimulus area A certainly supports this contention[2].

Gregory and Cane make the assumption that the number of independent observations n is proportional to the stimulus area A. Admittedly this is the simplest assumption; but there would seem to be good reasons for believing that the number of independent observations would more closely approximate the number of nerve fibres, f, operating in the area A, and f is certainly not proportional to A except perhaps for a limited range of areas in the fovea. If f is the correct estimate of the number of independent observations, $\Delta I/I$ should be proportional to $1/\sqrt{f}$. Using data on the variation of visual acuity across the retina to provide an estimate of f, $\Delta I/I$ is in fact proportional to $1/\sqrt{f}$ to a good approximation, over the wide range of stimulus areas from 10′ diameter to 40° diameter. There is some tendency for $\Delta I/I$ to be larger than predicted at very small field sizes, where eye-movements are probably a complicating factor, and at very large field sizes, where there is probably mental difficulty in utilizing simultaneously all the information supplied. If $\Delta I/I$ is plotted against $1/\sqrt{A}$ the results for field sizes up to about 2° are similar; but those for larger field sizes are markedly worse. Thus, for a field size of 36°, using $1/\sqrt{f}$ the predicted value of $\Delta I/I$ is about half the actual value, but using $1/\sqrt{A}$ the predicted value is about one-ninth of the actual value.

This type of statistical approach is very useful in tackling visual problems of this nature, and if certain assumptions are made it can lead to far-reaching conclusions. For example, if it is assumed that

$$N = f_1(c) \cdot f_2(I)$$

where N is the magnitude of the physiological response evoked by a stimulus of intensity I, and c is a measure of the state of adaptation, f_1 and f_2 being any functions, then by arguments given in the paper cited

$$N = N_0 + f_1(c) I^{r/k}$$

where N_0 is a constant, and r/k is the ratio of $\Delta N/N$ to $\Delta I/I$, $\Delta N/N$ being the physiological equivalent of the Weber–Fechner fraction. The above relationship implies a linearity between $\log (N - N_0)$ and $\log I$, and electrophysiological studies show that this is approximately true if N is the number of nerve impulses per second per nerve fibre.

I am grateful to Gregory and Cane for having directed my attention (in a private communication) to a slight error in the mathematics of my paper[2]; the conclusions of the paper are unaffected, but the matter will be discussed in a short note, which I hope to publish as a correction to the original paper.

Simultaneous Occurrence of 'Dawn Chorus' at Places 600 km. Apart

We have been observing whistlers and other naturally occurring audio-frequency noise at Wellington and Dunedin, New Zealand, since July 1955. The geomagnetic latitudes of these stations are 45° S. and 50° S. respectively, the distance apart being 600 km. approximately along a geomagnetic meridian. Certain of the whistler observations have already been described[1]; this communication deals with the simultaneous occurrence at the two stations of the phenomenon known as 'dawn chorus', which has been described by Storey[2] as consisting of a multitude of rising whistles, and sounding like a rookery heard from a distance. Dawn chorus is heard most frequently in the early hours of the morning and is correlated with magnetic activity; however, at present there exists no theory relating to its production or propagation.

Normally, during a period of dawn chorus activity, the rising whistles or tones occur at a rate of one rising tone every few seconds. However, occasionally a 'burst' of dawn chorus occurs, during which the rate exhibits a sudden and spectacular increase; thus a burst consists of a group of rising tones which arrive in abnormally rapid succession. Often the tones overlap, the high-frequency components of one tone arriving at the same time as the low-frequency components of the next tone.

Simultaneous recordings on magnetic tape have been made at the above stations on a schedule of 4-min. recording every 3 hr., usually on two consecutive days per week. Of the 273 simultaneous schedules recorded to date, dawn chorus has been heard at Wellington during 106, and at Dunedin during 64 schedules. In 56 cases dawn chorus has been heard at both stations during the same schedule.

An exceptionally clear display of dawn chorus was registered during the early morning hours of March 25, 1956. In particular, the schedule commencing at 1740 G.M.T. contained fine examples of bursts. The spectrograms of a portion of this schedule which contained 5 bursts are shown in superimposed form in Fig. 1. The rectangles of finite area are so drawn for clarity of display. Each one represents a line joining the two points marking the commencement (or leading edge) and the finish (or trailing edge) of a particular frequency component in the burst. Thus the leading edge can in general be identified with the first rising tone, and the trailing edge with the last rising tone, in the burst. It is seen that the bursts occur simultaneously at the two stations to within close time limits. Accurate timing was achieved by making all measurements with reference to the times of occurrence of loud 'bonks'[3]. By consideration of the possible propagation paths involved, it is found that these 'bonks' are coincident at the two stations to within 2 m.sec. The average difference in time of occurrence at Wellington and Dunedin for the bursts in Fig. 1, for all frequencies and including both leading and trailing edges, is less than 0·01 sec., while one-half of the individual time-differences is less than 0·1 sec. in magnitude. The leading edges tend to be more closely coincident than the trailing edges, one-half of the individual time-differences for the leading edges being less than 0·06 sec. This is probably because the first rising tone in a burst tends to be stronger than the last one, the timing of which is therefore more likely to be affected by background noise.

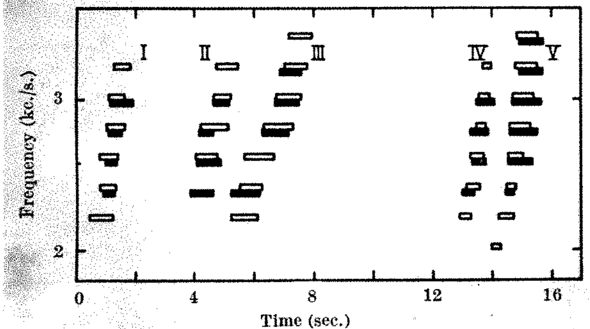

Fig. 1. Spectrograms of dawn chorus bursts. White rectangles: Wellington; black rectangles, Dunedin

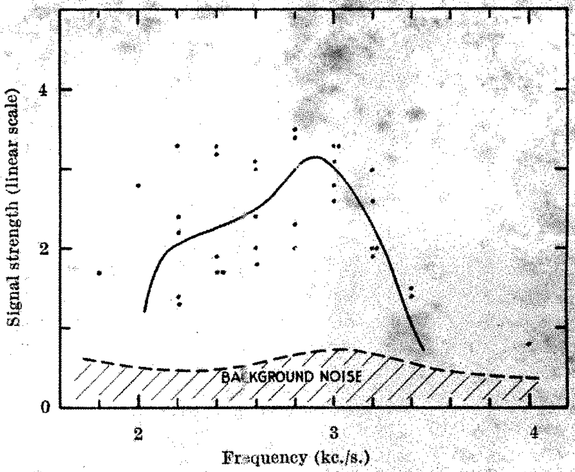

Fig. 2. Variation with frequency of the signal strength of dawn chorus bursts at Wellington

A supplementary set of spectrograms of these bursts taken at 6·6 times the normal speed did not reveal significantly closer coincidences. It is inferred, therefore, that the finite time-differences are not due to the experimental technique; but that at least the majority of these differences are real, and represent slight variations in the characteristics of the phenomenon at places separated by 600 km.

A noticeable feature of these bursts is that appreciable energy is received over a rather limited frequency range of less than an octave. Fig. 2 shows a mass plot of peak signal strength against frequency for all five bursts of Fig. 1, together with the average curve, showing a maximum of received energy just below 3 kc./sec.

No spectrograms have yet been made of an isolated rising tone. However, the detailed character of the rising tones in these bursts can be seen from Fig. 3, which shows on an expanded time-scale the shape of the leading edge of burst V of Fig. 1. The shape is also typical of both leading and trailing edges of bursts I and IV. After a relatively slow start, the pitch increases almost linearly from 2·6 to 3·4 kc./sec. This linear portion has an average slope of 2·0 kc./sec.^{2}, varying in actual cases between 1·5 and 3·0 kc./sec.^{2}. The other bursts shown in Fig. 1 (bursts II and III) do not appear at first sight to conform to the same pattern. However, aural observation shows that these latter bursts consist of a series of rising tones of even more limited frequency-range, the earlier tones in the burst containing only the lower frequencies, while in the later stages only the higher

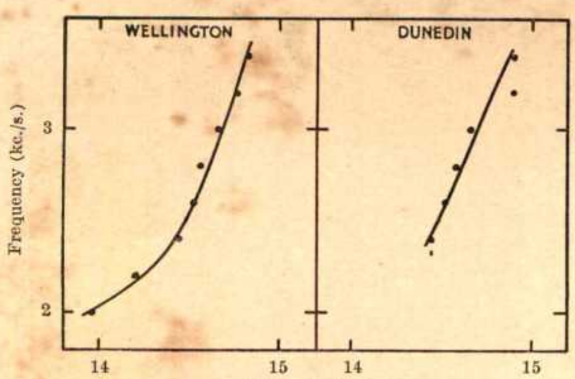

Fig. 3. Spectrograms of leading edge of burst V

frequencies are audible. This is also a feature of bursts of long duration heard at other times. The shapes of the leading edges for the lower frequencies, and of the trailing edges for the higher frequencies, generally match the respective portions of Fig. 3. Thus it is most likely that there is no basic difference in the characteristics of the rising tones throughout the schedule, apart from restriction of the frequency range in some cases.

A full discussion of these results and other data leading to a theory of dawn chorus will be published elsewhere. We are grateful to Dr. M. G. Morgan, of Dartmouth College, New Hampshire, U.S.A., for his encouragement and assistance in providing equipment for this project.

Beta-Gauge for Hair Measurements

The quantitative measurement of hair is an important factor in studies of heat exchange between animal and environment. Methods currently employed consist in counting the number of hairs per unit area, measuring the mean hair length, and determining the weight of hair per unit area. In measurements of hair number or hair weight per unit area a major error arises from the difficulty of measuring precisely an area on the mobile, elastic, non-planar skin of an animal. Any method requiring the removal of the hair for measurement changes the heat-transfer characteristics of the area, and repeat measurements cannot be made on the same area. An absorption-type beta-ray gauge would appear to offer a solution to the problem of measurement of the mass of hair per unit area. It would be a rapid, non-destructive, and reasonably accurate direct measurement of the mass of hair per unit area at the point of measurement.

A transmission-type beta-gauge for *in vivo* measurement of hair areal density must consist of a radiation source that may be placed on the skin of the animal with minimum disturbance to the hair, and a sensitive receptor a fixed distance from the source. In the present design, the beta-emitter was mounted in a 0·035-in. diameter depression in the side of a 0·094-in. diameter stainless steel rod attached by a light aluminium frame to a Geiger tube (Fig. 1). The radioisotopes used (promethium-147, thallium-204) were mounted as components of a fused enamel[1]. This method of mounting allows the maximum energy of the beta-emitter to be utilized because no absorbing material is introduced between the radionuclide and the detector. These two isotopes permit measurement of a wide range of hair densities. Promethium-147 becomes unusable at about 15 mgm./cm.^{2} and thallium-204 at about 80 mgm./cm.^{2}. The thickness of the stainless steel around the source (0·04 in.) is sufficient to provide saturation back-scattering at all beta energies used and also shields the animal from the source. This was demonstrated to prevent variations in count-rate due to variations in the proximity of bone to the surface of the animal.

A mica-window Geiger tube was chosen as the detecting element so that a minimum amount of radioactivity could be used in the gauge, since the necessity of having a large open volume around the source precludes the use of radiation shielding. The particular Geiger tube used (Anton Electronic Company No. 210-*H*) is supplied with the distal end threaded and thus becomes an integral part of the structure of the gauge.

The hair measurement beta-gauge was calibrated with aluminium absorbers. Measurements of hair density were made with this beta-gauge and compared with the density obtained by weighing the hair clipped from a measured area. Examples of these measurements are shown in Fig. 2 with the aluminium calibration curve for the gauge using thallium-204.

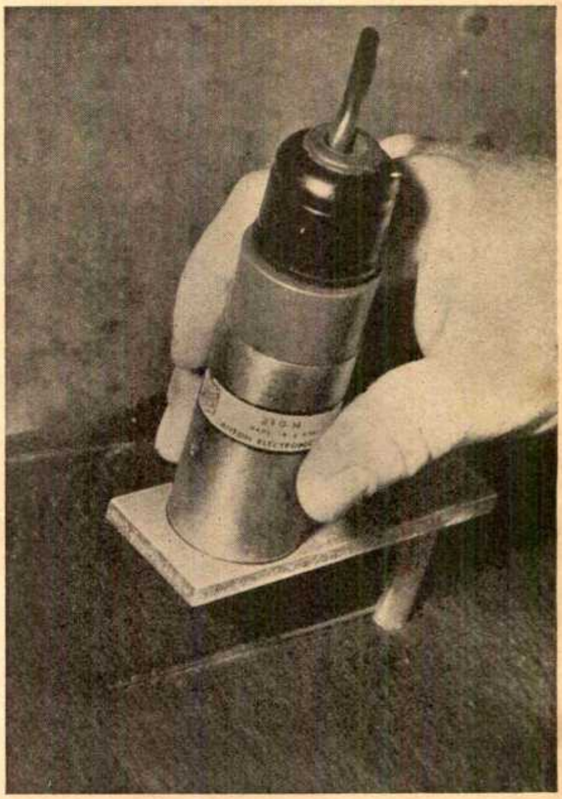

Fig. 1. Using the hair measurement beta-gauge. The thin probe is slid along the skin under the hair and the decreased count-rate noted. This is compared with a standard curve

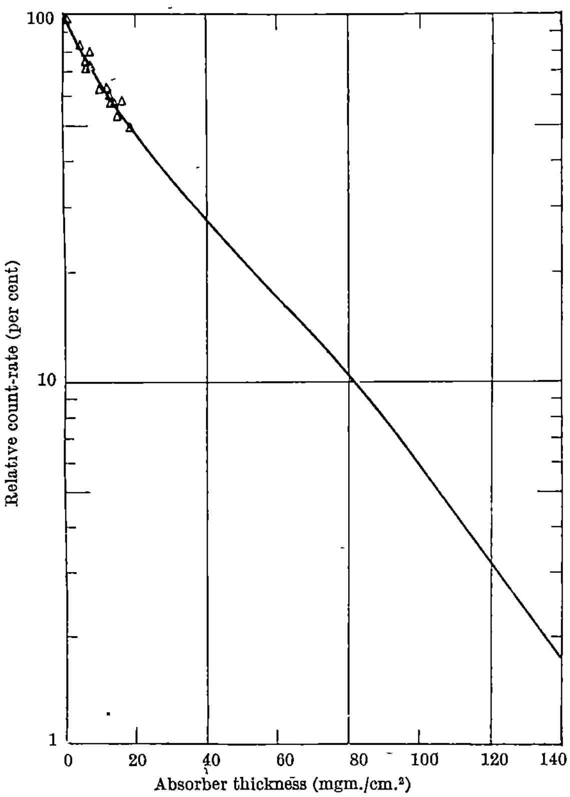

Fig. 2 Standard curve for the hair measurement beta-gauge using thallium-204. The points shown are for *in vivo* measurement of hair density in cattle

The precision of measurements obtained with the hair measurement beta-gauge was determined by repeated measurements on twelve cows. Two hundred and ninety comparisons indicate a probable error of ±4·4 per cent when the gauge was used with an integrating rate meter the time constant of which was equivalent to a standard error of ±2 per cent.

Details of construction and application of the gauge will be reported elsewhere. This investigation was supported in part by the Division of Biology and Medicine of the U.S. Atomic Energy Commission.

Effect of Alloying on the Energy-Levels of Inner Electronic Shells

When two elements such as copper and zinc are alloyed together there is a change in the distribution of the valence electrons; charge is transferred from zinc atoms to copper atoms. Thus Mott[1] has estimated that ~0·1 electron is transferred from zinc to copper in β-brass. Again, the calculated charge shift in a concentrated copper–zinc alloy is ~0·5 *c* electron transferred from each zinc cell to a copper cell, where *c* is the concentration of copper in the alloy[2]. In the latter case there is reasonably good agreement between the change in width of the valence electron energy bands for zinc and copper as observed experimentally and as calculated assuming that the energy-levels of the valence electrons in the alloy can be separated into two free-electron bands, one for zinc and one for copper, with a common Fermi energy.

However, on these simple views of alloying[2] one might expect that when, for example, electrons are transferred from zinc to copper atomic polyhedra in brass, there will be a shift towards higher energies of the whole energy band for the valence electrons of copper, plus a broadening of the band. Conversely, the zinc valence electron band may be expected to shift to lower energies coupled with a decrease in band width. One expects, then, both the upper and lower energy limits of the valence bands to change, the upper more than the lower, both bands having a common absolute upper limit—the Fermi energy.

But experimental X-ray spectroscopic measurements of dipole transitions from the valence bands to the atomic *K*-levels[3] indicate that although there are changes in intensity on the high-energy sides of the valence energy bands of copper and zinc, nevertheless the wave-length (and hence apparent energy) of the emission edge stays constant for both zinc and copper, to within experimental error. The energy band of copper broadens on alloying with zinc and hence the long wave-length (low-energy) emission of copper moves to longer wave-lengths and lower energies. Conversely, the long wave-length side of the zinc line moves to higher energies while, again, the high-energy emission edge is observed to stay constant. Similar behaviour is observed in other alloy systems which have been studied, although there are exceptions. Thus in nickel–zinc alloys a shift in the emission edge of the zinc band to lower energies is observed[4].

Experimental evidence thus largely appears to contradict the expected electronic behaviour on alloying. The following simple explanation is put forward to remove this contradiction. This is offered as an alternative to the proposal put forward by Friedel[5] to account for these observations.

Consider, once again, an alloy of copper and zinc. Charge transfer on alloying results in an electron, with a wave-function which will be a modified 4*s* function, moving away from a zinc polyhedron to a neighbouring copper cell. Now the amplitude of an *S*-state wave-function is large at the nucleus of the atom, and for a hydrogen-like 4*s* function the amount of electronic charge contained within the volume defined by the Bohr radius of the *K*-shell electrons is:

$$\varepsilon \sim \left(\frac{Z}{a_0}\right)^3 \left(\frac{a_0}{Z}\right)^3 \frac{1}{64\pi} \sim \frac{1}{200}$$

for one 4*s*-electron transferred from a zinc into a copper cell.

The energy change in the *K*-level of copper will thus be $\sim + 2.Z_{\mathrm{Cu}} \varepsilon = 13\cdot53\,n$ volts, where Z_{Cu} is the effective nuclear charge, ε is the additional very small screening introduced by one extra 4*s* electron introduced into the copper cell and *n* is the fractional charge shift. Thus if $n = \frac{1}{4}$ the energy change of the *K*-level is ~1 volt. The *K*-level of copper will be increased by ~1 volt and that of zinc will decrease by ~1 volt.

A more refined calculation using first-order perturbation theory has been carried out, and this predicts an energy increase for a 1*s*-state electron in copper to be $\sim 2 \cdot 6\,n$ volts, where n is the fraction of charge in a copper polyhedron, transferred from a zinc cell. The perturbing potential used was that due to the charge density of a 4*s* hydrogen-like wave function, and the wave function of the hydrogen-like 1*s*-state was assumed for the *K*-level. The maximum change in width of the energy band for copper in brass, that is, the difference in widths of the band in pure copper and that of very dilute copper in zinc solution, is $\sim 0 \cdot 9$ eV. Assuming that the electrons around the zinc and copper atoms have their energies distributed over a free electron spectrum based on respective ground-state energies[2], this change in width corresponds to an electron transfer of $\sim 0 \cdot 73$ electron into a copper cell for very dilute copper in zinc. The associated energy change of the copper *K*-level is thus $\sim 1 \cdot 9$ eV. Now the Fermi energy of the copper band will have its absolute energy raised by more than the increased width of the band, since it is estimated that the ground-state energy is itself raised by $\sim 1 \cdot 5$ times the increase in width of the Fermi band[2]. The Fermi energy will thus be raised in energy by an amount $\sim 2 \cdot 35$ eV., so that both it and the *K*-level increase in absolute energy (relative to an electron at rest in free space) by the same order over the whole range of alloys. In this case the emission wave-lengths for transitions from the top of the Fermi band to the *K*-shell will stay nearly constant with alloying, and the broadening of the Fermi band will appear as an increase in long wave-length transitions. The calculations are not accurate enough to predict whether the increase in absolute energies of the *K*-level and the top of the Fermi band will be the same to within experimental error; but the concept that this does occur, as discussed above, leads to a straightforward removal of a contradiction to the simple view of electron behaviour on alloying.

These arguments hold both for the emission and absorption spectra in alloys. In the former case, as Friedel has already discussed[5], the positive hole in the *K*-shell will be screened by a redistribution of the valence electrons in such a way that the Fermi-level remains constant. In this way Friedel accounts for the emission and absorption edges occurring at the same wave-length. Nevertheless, the effect described in this communication will still hold good whatever the details of the valence electron distribution.

I wish to thank Mr. A. D. Le Claire for providing the initial stimulus, and to thank him, Mr. J. Hubbard and Dr. H. M. Finniston for helpful discussions.

Effect of Pressure on the Dielectric Constant of Vitreous Silica

Since there are, to our knowledge, no reported observations of the effect of pressure on the dielectric constant of any solid, the data that we have obtained on this effect in vitreous silica may be of some interest, even though the precision of our results is low, and vitreous silica is far from being a typical solid.

In the course of calibrating a silica piezometer, we have determined the change with pressure in the capacity of the condenser formed by a silica tube with a silver coating fired on the outside, and filled with mercury extending well beyond the ends of the silver coat. This change is about ten times less than the change in the stray capacity between the silver coat and the metal shield in which the tube was mounted, and was determined by taking the difference of two runs, one with mercury in the tube and one without. The imperfect reproducibility of the stray capacity change has limited the precision of the final results to about ± 5 per cent of the maximum effect. The relative change in the dielectric constant of silica is given by $\frac{\Delta \varepsilon}{\varepsilon} = \frac{\Delta c}{c} - \frac{\Delta l}{l}$; for this computation we have used weighted means of published figures for the compressibility of silica. Fig. 1 shows $\Delta\varepsilon/\varepsilon$ to 4,000 kgm./cm.^{2}, at the temperatures 20° and 138° C. The limits of error are shown by vertical lines through the plotted points. All measurements were made at the frequency 2,500 c.p.s., with a maximum field strength of about 100 V./cm.

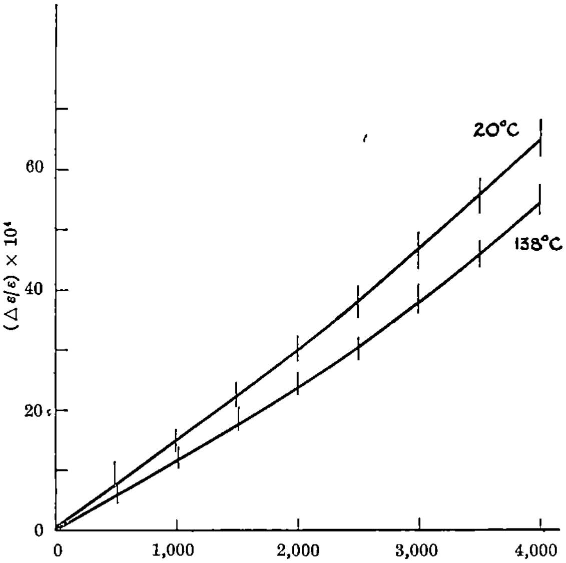

Fig. 1. $\Delta\varepsilon/\varepsilon$ vs. p for vitreous SiO_2

Within our limits of error, the molecular polarization $[P]$ of silica, proportional to $\frac{\varepsilon - 1}{\varepsilon + 2} \cdot \frac{1}{d}$, appears to decrease linearly under pressure, with a slope independent of temperature. The coefficient $\frac{1}{[P]} \cdot \frac{\delta[P]}{\delta p}$ has the value $-1 \cdot 6 \times 10^{-6}$ per kgm./cm.^{2}, about 3–10 times less than the values found for most of the non-polar liquids that have been studied under pressure.

We wish to thank Mr. Arthur K. Doolittle and the Carbon and Carbide Chemicals Co. for support of this work.

John Reitzel

Arthur D. Little, Inc.,
Cambridge, Mass.

June 15.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, October 29

Royal Geographical Society (at 1 Kensington Gore, London, S W.7), at 5 p.m.—Mr. E. H Brown. "Physique of Wales".

Monday, October 29—Friday, November 2

Institution of Electrical Engineers, Radio and Measurement Sections (at Savoy Place, London, W.C.2).—Convention on "Ferrites".

Tuesday, October 30

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p m.—Dr. H. Kalmus · "Behaviour and Heredity"*.

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Symposium on "Side Spillways".

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Mr J. R. Shakeshaft: "Radio Astronomy"*.

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C 1), at 5.30 p m.—Prof. E. C. Amoroso: "Endocrinology and Pregnancy"*. (Sixth of fourteen lectures on "The Scientific Basis of Medicine". Further lectures on November 1, 6, 8, 15, 20, 22, 27 and 29.)

Society of Instrument Technology (joint meeting with the Control Section, at Manson House, Portland Place, London, W 1), at 7 p.m.—Mr. D S. Townend. "Control Engineering and the Automatic Process Plant".

Royal Aeronautical Society, Graduates' and Students' Section (at 4 Hamilton Place, London, W.1), at 7.30 p m.—Mr. E. P. Hawthorne: "Nuclear Power for Aircraft".

Wednesday, October 31

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p m.—Dr. W. S. Pitcher and Dr. R. C Sinha: "The Petrochemistry of the Ardara Aureole"; Mr. Bryan P. Ruxton. "Notes on Some Important Contacts in Hong Kong".

University College, London (in the Gustave Tuck Theatre, Gower Street, London, W.C 1), at 5.30 p m.—Dr. M. Dunand: "Néolithique et Enéolithique à Byblos". (First of three Special University Lectures in Archæology (to be delivered in French) Further lectures on November 1 and 2.)*

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C.1), at 6 p.m.—Annual General Meeting. 7.15 p.m.—Mr. George A. Marriott—Presidential Address.

Institution of Mechanical Engineers, Engineering Production Group and Education Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p m.—Discussion on "Selection and Training of Engineering Designers".

Thursday, November 1

Chemical Society (in the Chemistry Department, University College, Gower Street, London, W.C 1), at 2.30 p.m.—Symposium on "Newer Interpretations of Reactions and Structure in Carbohydrate Chemistry".

Linnean Society of London (joint meeting with the Systematics Association at Burlington House, Piccadilly, London, W.1), at 4 p.m.—Discussion on "The Inheritance of Acquired Characters".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4 30 p.m.—Dr. E. F. Gale, F.R.S.: "The Biochemical Organization of the Bacterial Cell".

Mineralogical Society (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p m —General Meeting

University of London (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 5 p.m.—Prof. Georges Portmann (Bordeaux) "The Physiology of Phonation"* (Semon Lecture).

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p m.—Prof L. Dudley Stamp. "Conservation of Land". (Third of a series of six lectures on "The Conservation of Natural Resources".)

Institute of Metals, London Local Section (at the Royal School of Mines, South Kensington, London, S.W.7), at 7 p.m.—Prof F. C. Thompson: "Primitive Metallurgy".

Royal Institute of Chemistry (at the Technical College, Fassett Road, Kingston), at 7 p.m.—Dr. Tudor S. G. Jones "Chromatography".

Friday, November 2

British Psychological Society, Industrial Section (in Room 425, Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 6 p.m —Mr. L. J. Holman: "Some Differences between Potential Officers from North and South England".

Institution of Mechanical Engineers, Internal Combustion Engine Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. P. F. Ashwood: "A Review of the Performance of Exhaust Systems for Gas-Turbine Aero Engines".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1). at 6.30 p.m.—Mr. J. R. Gass · "Automation"*. (Fourth of ten University Extension Lectures on "Technology and Industry". Further lectures on November 9, 16, 23, 30, December 7 and 14.)

Society of Cosmetic Chemists of Great Britain (at the Royal Society of Arts, John Adam Street, Adelphi, London, W C.2), at 7.30 p m.—Mr. T. W. Watson. "Silicones in the Cosmetic Industry".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. Tom M. Harris, F.R.S. · "The Investigation of a Fossil Plant".

Saturday, November 3

British Interplanetary Society (in the York Hall, Caxton Hall, Caxton Street, London, S.W 1), at 6 p.m —Dr. R. M. Goody "The Atmosphere of Mars".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistants in Mathematics—The Secretary of University Court, The University, Glasgow (October 31).

Demonstrator (graduate in metallurgy or chemistry) in Metallurgy—The Registrar, Manchester College of Science and Technology, Manchester 1 (October 31).

Technician (A.I M L.T. or equivalent) in the Chemical Pathological Laboratory—The Group Secretary, North Middlesex Hospital, Edmonton, London, N 18 (November 3).

Divisional Physicist (with a good honours degree in physics and preferably some experience in industry), to organize and lead the Divisional Dust Suppression Team, collaborate with the areas in investigations on ventilation and illumination, and work to stimulate the adoption of scientific methods of control—The Staff Department (A.3), National Coal Board, Northern (N. and C) Division, Whitely Road, Longbenton, Newcastle-upon-Tyne 12 (November 7).

Biochemist, Senior grade, to work under the Director of the Department of Clinical Biochemistry—The Administrator, Radcliffe Infirmary, Oxford (November 10).

Lecturer in Mathematics at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 10)

Lecturer in the Department of Bacteriology—The Secretary, The University, Edinburgh (November 10).

Research Statistician (with a good knowledge of biometric techniques and a special interest in the design and analysis of experiments), to work under contract with Torry Research Station (D.S I.R Food Investigation Organization)—The Secretary, The University, Aberdeen (November 10).

Chemist (Research Officer) (with at least a university degree with first- or second-class honours, and preferably research experience in inorganic or physical chemistry) with the Australian Atomic Energy Commission, to undertake research into the effect of radiation on nuclear fuel materials and other reactor components, and to assist in a programme of nuclear fuel development—Officer-in-Charge, A.A.E.C. Research Establishment, Private Mail Bag, Sutherland, N S.W., Australia (November 12)

Public Analyst and Government Bacteriologist in the Isle of Man—The Government Secretary, Government Office, Isle of Man (November 15)

Research Assistant in Soviet Institutions—The Secretary of University Court, The University, Glasgow (November 15).

Senior Lecturer in Chemical Engineering at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Cape Town, November 15).

Chair of Philosophy in the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C 1 (November 16).

Soil Physicist (with a good second-class honours degree in chemistry and/or physics) to carry out physical and nutrient determinations of irrigated soils; an Agronomist (with a university degree in agriculture or natural science or a diploma of an agricultural college of university status which has involved at least a three-year course of study, plus one year postgraduate or post-diploma training in agricultural science) to study and determine the agronomic and economic possibilities of both irrigated and unirrigated crops; and an Irrigation Engineer (with a good degree in agricultural engineering and specialized in land engineering) to be responsible for the preparation of fields, layout of field irrigation channels and the determination, in conjunction with the Soil Physicist and Agronomist of the times and amounts of irrigation—The Secretary for Recruitment, Gold Coast Civil Service, 13 Belgrave Square, London, S.W 1 (November 16).

Research Engineer or Physicist (with a university honours degree in mechanical or electrical engineering, or in science with physics as the major subject, or equivalent qualifications, together with some research experience) in the Sheep Biology Laboratory, Division of Animal Health and Production, Commonwealth Scientific and Industrial Research Organization, Prospect, New South Wales, Australia, to collaborate with biologists in the research programme of the climate physiology group—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C.2, quoting Appointment No. 205/108 (November 17).

Research Officer (with an honours degree in science or equivalent qualifications with physics or chemistry as major subjects, together with some research experience) In the Division of Industrial Chemistry, Commonwealth Scientific and Industrial Research Organization, Fisherman's Bend, Melbourne, Victoria, Australia, to undertake a study of the nucleation and growth of crystals, in particular to study the growth of ice crystals from the vapour phase on such nucleating material as silver iodide—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 590/601 (November 17).

Senior Lecturer (preferably with experience of research in the solid state field) on the staff of the Department of Physics, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, November 19).

Director of the Institute for Social Research, University of Natal, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, November 23).

Bosch Chair of Histology and Embryology in the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, November 26).

Associate Professor in Mining Engineering at the New South Wales University of Technology, Sydney—The Agent General for New South Wales, 56 Strand, London, W.C.2 (Australia, November 30).

Lecturer (honours graduate in biochemistry or chemistry with postgraduate experience in biochemistry and preferably with an interest in comparative biochemistry) in Biochemistry at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C 1 (Australia, November 30).

Lecturer in Agricultural Zoology at Makerere College, University College of East Africa—The Secretary Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C 1 (November 30).

Senior Lecturer (preferably with primary interest and experience in fluid mechanics) in Mechanical Engineering at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C.1 (Australia, November 30).

Assistant in Physiology in the Department of Physiology and Biochemistry—Joint Clerk to the University Court, Queen's College, Dundee (December 1).

Commemoration Fund Research Fellow (woman graduate of any university), for research in mathematics, natural sciences or an allied subject—The Secretary, Girton College, Cambridge (January 15).

Assistant Lecturers (2) in Physics—The Secretary, Royal College of Science and Technology, George Street, Glasgow.

Biochemist, Basic grade (graduate, preferably with experience in, and a knowledge of chromatographic methods), for research work in problems of metabolism in mental deficiency—The Physician Superintendent, St. Lawrence's Hospital, Caterham, Surrey.

Entomologists (with a good honours degree in zoology and training in entomology) in the Department of Tsetse Control, Gold Coast Local Civil Service, to investigate various aspects of the bionomics and ecology of tsetse flies in relation to man and animals and to supervise control measures under the Director of Tsetse Control—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.77/13/01.

Industrial Chemist (with an honours degree in chemistry or membership of the Institution of Chemical Engineers, and at least ten years experience as a chemist in industry since qualifying) in the Department of Heavy Industries, Eastern Region, Nigeria, to advise on the design of a laboratory and subsequently direct its work, and to undertake research into local raw materials, organic and inorganic, and their potential utilization either alone or in combination with imported material—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.461/411/02.

Laboratory Technologist (male or female, with A.I.M.L.T or equivalent, a knowledge of biochemistry and forensic and anthropological experience) in the Kenya Government Police Department—The Crown Agents, 4 Millbank, London, S.W.1, quoting M.3/43685/NF.

Laboratory Technologist (male, preferably single and preferably A.I M.L.T., and experienced in laboratory techniques and animal handling) in the Tanganyika Government Veterinary Department, for laboratory duties and field work on animal disease problems —The Crown Agents, 4 Millbank, London, S.W.1, quoting M 3/35063/NF.

Lecturer in the Department of Chemistry—The Principal, The Percival Whitley College of Further Education, Halifax.

Physicist in charge at the Northern Ireland Radiotherapy Centre—The Secretary, Northern Ireland Radiotherapy Centre. Purdysburn, Belfast.

Physicist, Senior grade (with a knowledge of X-rays, radium and radioactive isotopes) in the Radiotherapy Department, for duties concerning routine radiotherapy physics, and the applications of radioactive substances in other branches of medicine—The Secretary to the Board of Governors, Charing Cross Hospital, London, W.C 2.

Principal/Senior Scientific Officer (with a first- or second-class honours degree in mathematics, and several years postgraduate research experience in applied mechanics), to provide general theoretical assistance to a group engaged on the development of nuclear reactors for military application (Ref. No. 1299/34); and a Scientific Officer (with a first- or second-class honours degree in physics, mathematics or engineering, or equivalent qualifications), to carry out research and development work in the field of applied mechanics (Ref. No. A.1221/34)—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting appropriate Ref. No

Research Assistant (with either (*a*) a degree in chemistry or physics and an interest in the physical-chemistry of viruses and other biological macromolecules, or (*b*) appropriate laboratory experience) in the Biophysics Department—The Secretary, Research Institute (Animal Virus Diseases), Pirbright, Surrey.

ANALYSIS OF DEFORMATION

Volume III—Fluidity

by

Keith Swainger

Ph.D.(Eng.), London

Size: 8¾ in. × 5½ in. *294 pages* *Illustrated* *65s. net*

In this third volume of his treatise, Dr. Swainger develops further and applies the flow aspects given briefly in volume one. He examines critically the classical approach to fluid mechanics, and also considers the extent to which the new continuum theory agrees with the classical theory of hydrodynamics.

D.Sc.(London and Bristol), D.I.C., F.R.I.C.

VOLUME TWO—FOURTH EDITION—REVISED & ENLARGED

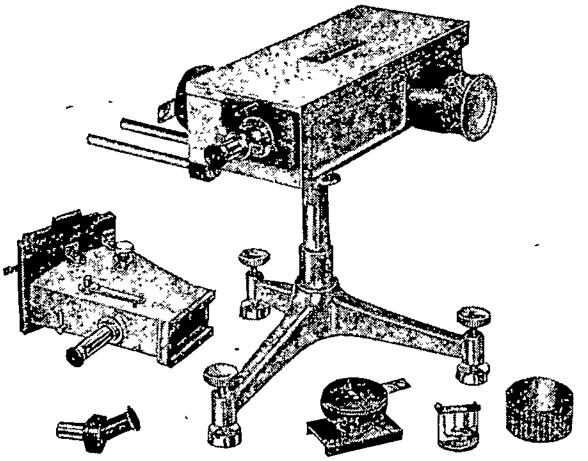
Size: 8¾ in. × 5½ in. *508 pages* *Illustrated* *75s. net*

The first volume of this standard work deals mainly with the theory and methods of determining hydrogen-ion concentration or activity. This second volume examines the part played by hydrogen ions in chemistry and its numerous technical processes in industry. It has had the same careful revision as volume one which appeared exactly a year ago.

37 ESSEX STREET, LONDON, W.C.2

PRECISION INSTRUMENTS

Direct Reading Wavelength Spectrometer



for use in the visible spectrum and also, when required, in the ultra violet and infra red. Reading in wavelengths directly.

A camera attachment can be supplied giving the following length of spectrograms :

With quartz prism, wavelength 10,000 A. to 2,200 A., 70 mm.

With glass prism, wavelength 10,000 A. to 3,600 A., 125 mm.

A large range of accessories can be supplied with this spectrometer, making it a really universal instrument, and our staff will at all times be pleased to recommend the equipment most likely to meet special requirements.

SCIENTIFIC AND INDUSTRIAL RESEARCH IN THE UNIVERSITIES

THE problem of finding the money for carrying out research in university departments of science and technology in Britain has been growing steadily more acute, and there has been considerable discussion in recent months which has served to show both its magnitude and the difficulties inherent in meeting it. Prof. Samuel H. Beer has produced a timely little book* which demonstrates that something in the way of positive, constructive thinking is required if we are not to drift in some emergency into a situation which will endanger both the autonomy of the universities and the balance, or even the conduct, of research in general.

Prof. Beer is concerned simply with the role of the Treasury as co-ordinator of financial and economic policy, and in the first place he is impressed with the Treasury's lack of positive powers of command. But the picture he gives of the way in which the Treasury is able in practice to enforce effectively the priorities of Government policy indicates the importance of institutions or activities subject to Government control, such as the University Grants Committee or the Department of Scientific and Industrial Research, being ready and able to present a clear and reasoned argument for their needs which can be fully justified by reference to national needs. The Treasury does possess some powerful sanctions; but supporting these is a 'structure of influence' that enables it to carry out most of its wishes by persuasion. This is the important factor where such activities as research and institutions like the University Grants Committee are concerned.

In this attempt to understand the relations of the Treasury with the other great Departments of State, Prof. Beer notes a strong tendency to reach agreement at the official level which has roots in the corporate life of the Civil Service. It has frequently been suggested that one of the reasons for the smooth working of the University Grants Committee system is that the senior Civil servants concerned have themselves a university education and outlook, and a like factor can operate also in relation to Ministerial collective responsibility. Where this operates and Ministers know their own minds, the co-ordination works smoothly. Officials are able to go beyond the mere departmental view and anticipate probable decisions at Ministerial level. In its absence, however, and where Ministers cannot agree, the whole process may break down.

But Prof. Beer's tribute to the efficiency of Civil Service administration at the highest level does not deal with one vital point. If he is correct in his view that the power of the Treasury resides largely in the tendency to agreement proceeding from the professional standards of the Civil Service and from the structure of Britain's executive power, that of itself affords no assurance that the right agreements will be reached. It says nothing as to whether the Treasury is properly equipped for reaching right decisions in matters of planning, or as to whether the standards of efficiency which it applies in such matters as research, for example, are in line with modern conceptions and practice. Tendencies to agreement at any level will not ensure sound decisions unless there is clear understanding on all sides of the nature of the problem, including the scientific and technical factors involved.

Prof. Beer's little treatise is thus less reassuring than appears at first sight, and by implication his exposition of the nature of Treasury control reinforces all the arguments for ensuring that the future administrator has an adequate understanding of the nature of the scientific and technical problems in the situations and problems he will have to confront. It indicates, too, the value of making the fullest use of those scientists who possess administrative ability, and it should remind the scientist and technologist of the importance of taking care that the nature of their work and the conditions required for its effective pursuit are clearly explained to those from whom the means for its prosecution are drawn.

This question of public relations is of vital importance both in relation to university research, which clearly is not easily separated from the activities of the universities as a whole, and in relation to the nation's general research organization. Understanding and foresight are essential if the delicate balance is not to be disturbed, and waste of public resources through some ill-judged and short-sighted economy avoided. It might well be that, as was urged in the debates on the Department of Scientific and Industrial Research Bill in the House of Commons, a senior Minister, provided with an adequate staff, and charged with the responsibility for co-ordination and prosecution of our scientific and technical effort, could do something to improve the present position Apart altogether from the question whether any one man could adequately meet the demands which such a responsibility would make upon him, he could only hope to do so under exactly the conditions which Prof. Beer lays down for effective Treasury control in general, and presupposing a wide degree of understanding of the scientific and technical factors on the part of those with whom he is called upon to deal.

What needs to be emphasized is that a wide degree of public understanding is essential before we can hope to arrive at the most efficient and appropriate structure for the administration of Britain's research effort. To some extent recent debates in Parliament have assisted that process; but there is still much that the Parliamentary and Scientific Committee, for example, could do in this direction. Further, if Britain is indeed lagging behind the United States in expenditure on research, as the preliminary estimates from the survey made by the Department of Scientific and Industrial Research suggest, the situation is not likely to be improved by administrative action done in the absence of such wider understanding. A change in the climate of opinion may be an essential for the necessary financial provision to be forthcoming and for the effective presentation of research. As Sir Harold Himsworth pointed out at the Home Universities Conference held last winter, neither universities nor research organizations alone are able under modern conditions to carry the whole breadth and depth of the research required for the support and development of modern society. Both must contribute, and as partners in the full sense of the word. Whatever the future relation between them and between them and the Government, nothing should be done which impairs the independence of the universities and their freedom to develop according to their own inspirations. Prof. H. W. Melville had referred during the Conference to the possibility that the Department of Scientific and Industrial Research might provide a means of redressing the balance of fundamental research when it was found that certain subjects were neglected in the universities. It would be undesirable for any Government department to induce, by direct action, the universities to undertake investigations which they do not at present pursue, even though such researches might be in the national interest; but Prof. Melville thought that either by undertaking the investigation itself or by adopting the unit system by which the Medical Research Council and the Agricultural Research Council at present operate in the universities, the Department of Scientific and Industrial Research could exert a marked influence.

---

* Treasury Control: The Co-ordination of Financial and Economic Policy in Great Britain. By Prof. Samuel H. Beer. Pp. ix+138. (Oxford: Clarendon Press; London: Oxford University Press, 1956.) 15s. net.

Here we see at once how important it is that there should be a full understanding of the nature of the Department's work and a balanced view of the country's needs, without which the necessary resources are unlikely to be forthcoming. Moreover, that applies equally to Sir Harold Himsworth's point about the access of individual universities to specialized facilities which they need but which they do not possess, and which it would be undesirable and uneconomic to duplicate in every university, particularly as they are available in many research institutes and stations. This is a particular aspect of the problem of the proper association of existing major research institutes and establishments with the appropriate university departments that can affect very considerably the return which the country receives from its expenditure on research and on the universities.

These are some of the problems which the universities, the research councils and research associations should be considering, and they determine the value which is received for expenditure on research. Moreover, while, as has been emphasized, appropriate solutions are unlikely to be found or at least applied in the absence of a wider and fuller public understanding of what is involved, that public understanding could simultaneously help to remove the most serious weakness to which the survey described by Mr. E. Rudd in a paper before Section F (Economics) at the recent Sheffield meeting of the British Association points—the much smaller expenditure on research by industry in Britain. If industry is to increase its own effort, still more to increase those benefactions to university research which can decrease the risk of excessive dependence on government support or contract research, it will only be in the light of fuller understanding of the nature of research and of the contribution which scientific advance can make to industrial development and efficiency. While the magnitude of Britain's effort in research and development may well be open to inquiry, and the structure of the national organization for research requires critical thought and inquiry, the overriding need is for fuller public understanding of what is involved, and of the dependence of our industrial effort not only upon research but equally upon technological and technical education.

GENEVA CONFERENCE ON THE PEACEFUL USES OF ATOMIC ENERGY

Proceedings of the International Conference on the Peaceful Uses of Atomic Energy

Held in Geneva, 8 August–20 August, 1955. Vol. 15: Applications of Radioactive Isotopes and Fission Products in Research and Industry. Pp. viii+327. 7.50 dollars; 54*s.*; 32 Swiss francs. Vol. 12: Radioactive Isotopes and Ionizing Radiations in Agriculture, Physiology, and Biochemistry. Pp. ix+553. 9 dollars; 63*s.*; 39 Swiss francs. Vol. 10: Radioactive Isotopes and Nuclear Radiations in Medicine. Pp. x+544. 8 dollars; 57*s.*; 34 Swiss francs. (New York: United Nations; London: H.M. Stationery Office, 1956.)

IT was said, I think first by Robert Oppenheimer, that the increase of knowledge as the result of the widespread use of radioactive tracer elements in research might bestow greater benefits on mankind than would result from the mere supply of energy from uranium fission. These three volumes present a very comprehensive review of what has been achieved thus far with tracer elements and with massive doses of radiation derived either from elements such as cobalt, left in a high-flux reactor for a long time, or from fission products. The nuclear power industry will yield tons of fission products a year in a decade, and scientists have been searching for possible uses of the thousands of millions of curies of radiation which will be available as a by-product. Before the end of the century, fission-product radiation could sterilize far more food than the population using the related nuclear energy could consume: such is the magnitude of the new source of energy.

Research with radioactive tracer elements was initiated more than forty years ago by Prof. G. de Hevesy, who was present at Geneva. Many papers on a large number of subjects have their origin in his work. Great strides have been made in chemical analysis by irradiation of samples in a neutron flux of $10^{12}n/\text{cm.}^2/\text{sec.}$; many impurity elements can then be detected in concentrations of one part in a hundred million, and for a few elements the sensitivity is a thousand times greater than this. Trace impurities can seriously affect the semiconducting characteristics of germanium and silicon, and both have benefited by activation analysis; it also offers a great advantage over other possible methods when the impurity element has chemical properties similar to the host element. Most of the papers on this subject are indicative: the authors recognize that the subject, although old, is far from fully developed, and results are offered as a guide. Tracers have been used in the study of the mechanism of chemical reactions, the function of catalysts, absorption and desorption, and in many metallurgical problems. When a radioactive metal diffuses into another metal, the influence of the grain boundary on diffusion-rates can be studied precisely.

The technological importance of isotopes is exemplified in the very large number of papers which report the use of isotopes as gauges, gauges for thickness measurements ranging from 0·0001 in. for inks, paints and electroplating up to 2 in. of steel and 15 ft. of snow. Locating gauges have been used in fluid dynamics for indicating interfaces, the degree of mixing of gases, of liquids and of solids; flow gauges to follow the movement of silt in river beds and sand in harbours; and density gauges for the manufacture of cigarettes and for liquids in pipe lines. In the study of wear and the influence of lubrication on wear, isotopes have been widely used; recent Soviet work is reported on this subject, and there is an extensive survey of the use of isotopes in the steel-making industry of the U.S.S.R.

Strong sources of radiation can replace X-ray tubes for certain radiographic purposes. Thousands of curies of iridium, emitting 600-keV. γ-rays, are used for boiler weld radiography, and in time cæsium-137 separated from other fission products will doubtless more than satisfy all possible needs for γ-rays in this energy-range. Thulium, emitting γ-rays of 84 keV. energy, has been made up into extremely portable X-ray units for field use—again, thulium may possibly be superseded by the fission product xenon. Cobalt-60 has practically ousted radium in the γ-ray energy-range of 1–2 MeV. for medical therapeutic use.

The role of fission products in human history lies n the unforeseeable future. At present we see the use of γ-rays to break chemical bonds and polymerize and cross-link many molecules such as polythene and rubbers; but only a beginning has been made. The sterilization of foods and pharmaceuticals has been studied for years with some success; but a ten-year summarizing paper still speaks very cautiously of the future possibilities of the widespread use of fission products; the direct conversion of radiation into electrical energy appears to have little future except for special restricted applications.

Those scientists who do not work in the life ciences will enjoy many fascinating papers in Vols. 10 and 12, on radioactive isotopes and nuclear adiation in medicine and in agriculture, physiology and biochemistry. There are lengthy accounts from many countries of the use of tracers in agriculture, especially in the study of root and leaf fertilizers, plant growth, and the speed of chemical processes aking place in plant life. Labelled phosphate fertilizers are now made by the ton, so great is the demand or agricultural research, and accurate information n the absorption through the leaves may revolutionize crop fertilization. Isotopes led to the discovery f extensive root-grafting of trees—a forest must be onsidered as a united community rather than as a collection of individuals—and the danger of fungus invasion by the root system is thus more obvious. It is disquieting to learn that the weedkiller 2-4-D can be absorbed by edible plants, and it is clearly important, as one review article points out, to establish that such compounds have no effect on the consumer—man or animal.

Mutations induced by irradiation are being studied in the radiation fields at Brookhaven, and in Norway, the U.S.S.R. and elsewhere. It is not easy to judge whether really important mutants have been discovered yet—mutants which have not already been developed by intensive breeding, the rust-resistant oats, the improved peanuts, the more erect variants of barley, etc. Improvements are expressed by writers only in terms of small percentages, and one wonders what commercial advantage red carnations grown on a white carnation stock will have. But patience is needed, and progress is being made on a wide front. Among the valuable uses of intense sources are to be included the eradication of the screw worm fly by sterilization of large numbers of male flies with doses of 7,500 roentgens; in this way the island of Curaçao has been freed from this damaging pest. The treatment of potatoes and carrots with a similar γ-ray dose completely inhibits sprouting and growth for a year.

Pavlov's plea for an exact knowledge of the fate of food within organisms is likely to be answered now that tracer elements are in wide use. It comes as a surprise to learn that calcium is constantly passing from blood to bone and back again. For example, one writer reports that 99 per cent of labelled calcium is deposited in the bone within one day of ingestion, and the amount of calcium exchanged to and fro is a hundred times the amount retained for growth. The speed of some reactions is very great; thus, within ten minutes of adding chlorine ions to the blood, equilibrium is established between plasma and red cells. Photosynthesis is yielding up some of its mysteries with the aid of carbon-14, and many papers are devoted to this huge subject. At first, says one contributor, it seemed that the use of isotopes would solve most of the more difficult problems of animal nutrition; many answers have been supplied by isotopes, but not the simple ones which were expected, and a more complex state of affairs has been uncovered.

Apart from an extensive use of tracers in medical research, medical diagnosis and therapy have benefited greatly from the ready availability of radioactive sources. Diagnosis by iodine uptake of the malfunctioning of the thyroid gland is one of the oldest. More recently, radioactive iodine and arsenic have been used for location of metastases of tumours; where great accuracy of location is required, as for the location of brain tumours, the positron-emitter arsenic-74 is used, and two scintillation counters placed on opposite sides of the head record coincidence counts if the two γ-rays which are emitted simultaneously and in opposite directions when the positron decays pass through the counters. Radioactive iron is used in diagnosis of diseases affecting bone marrow, and radiochromium or radiosodium is used in the study of the circulation of the blood. Many more diagnoses with radioactive elements are in the research stage and show great potential value, although few are ripe for routine laboratory use; the future for accurate diagnosis appears to the layman to be far brighter than the past has been.

Radiation therapy has benefited by the large use of strong radiocobalt sources in place of radium bombs emitting a far lower intensity of radiation. Cæsium-137, which emits a rather softer radiation of 660-keV. energy, is just becoming available from fission separation plants and will supply all conceivable needs of therapy in a decade or so. Iodine selectively absorbed can be used in large doses for therapy, and so can phosphorus; gold in colloid form has been injected locally, and a new technique involves the irradiation of intravenously injected boron in a slow-neutron beam emerging from a reactor.

Vol. 10, on the use of nuclear radiations in medicine, is one of the most remarkable volumes from the Geneva Conference, and one of the most inspiring.

T. E. ALLIBONE

SCIENCE IN PROGRESS

Science in Progress

Edited by George A. Baitsell. Ninth Series. (The Society of the Sigma Xi devoted to the Encouragement of Research in Science. Sigma Xi National Lectureships 1953 and 1954.) Pp. xviii+343. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1955.) 6.50 dollars; 52*s*. net.

THIS new volume, the ninth in the series of "Science in Progress" publications, which began with Vol. 1 in 1939, continues the firmly established function of the series: the presentation in permanent form of authoritative reports of research in both pure and applied sciences. George A. Baitsell has produced an engaging and varied mixture of topics. It would be unfair to say that the accounts are couched in popular language; but generally they are not loaded with heavy technicalities.

A reader with a grammar school knowledge of chemistry and biology will find Kenneth V. Thimann's paper on the physiology of growth tissues easy to understand; but a specialized knowledge of mathematical aerodynamics is necessary to comprehend fully the second part of D. B. Steinman's account of the stability of suspension bridges. The first part of this chapter makes exciting reading. It tells of the unexpected destruction of suspension bridges which were able to absorb energy from winds of quite moderate velocity and sustain themselves in oscillation. An example occurred in late 1940 when the Tacoma Narrows Bridge at Paget Sound, new only four months previously and built at a cost of six and a half million dollars, was destroyed. The oscillations of the bridge increased to destructive amplitude until the main span broke up and dropped into the water 208 ft. below. The problem concerning this has been solved both theoretically and practically.

In a forty-page chapter, Lawrence M. Snyder, professor of genetics in the University of Oklahoma, gives a summary of the present knowledge of human heredity, with special reference to clinical problems, some of which are of rare occurrence. This is followed by a discussion by Curt Stern, of the University of California, on the cellular physiology of differentiation by means of which an embryonic cell is transformed gradually and in the end, usually irreversibly, into a differentiated cell. His investigations, which were suggested by the arrangement of bristles on the fruit-fly, carry the knowledge of this topic further forward; but in general the nature of the mechanisms of differentiation is still obscure.

E. J. Krans, of Oregon State College, is the author of a chapter, easy to read but thoroughly sound, on the significance of ergocrines in agricultural practice. In this well-illustrated chapter the author considers the effects of the synthetic plant-hormone substances both as plant-growth stimulants and as herbicides. The processes of visual excitation provide an instance of a biological problem which is investigated on the molecular level. George Wald, of Harvard University, has given a thorough, clear and authoritative account of the biochemical and physical properties of retinal molecules and their function in seeing.

Lee E. Farr, of the Brookhaven National Laboratory, presents a paper on the impact of nuclear science on medicine. This is by no means well-trodden ground, for, among other important matters, he gives accounts of the effects of radiation on immunity mechanisms, the use of carbon isotopes for exploring the methods by which amino-acids are converted to protein in living tissues, and the radiation of brain tissue. Felix Bloch, of Stanford University, gives an account of the apparatus and methods used for investigating nuclear magnetism, which is a model of clarity and simplicity in exposition. In particular, the technique is applied to a detailed study of molecular structure.

Two other chapters maintain the high quality of the others: transistor physics, by William Shockley (Bell Telephone Laboratories); and colour and chemical construction, by Wallace R. Brode (National Bureau of Standards, Washington, D.C.). Although these two subjects have been covered adequately in papers and articles published in Britain, the American method of presenting the material should prove to be instructive.

The book is a handsome volume, well printed and illustrated, on good paper, and worthily bound.

W. L. SUMNER

THE NATURAL HISTORY OF SPACE PERCEPTION

The Child's Conception of Space

By Jean Piaget and Barbel Inhelder. Translated from the French by F. J. Langdon and J. L. Lunzer. (International Library of Psychology, Philosophy and Scientific Method.) Pp. xii+490. (London: Routledge and Kegan Paul, Ltd., 1956.) 42*s*. net.

THIS is an important book, probably the most notable of the long series of similar studies on child development which have come from Prof. Jean Piaget's laboratory. In it the developing powers of the child to manipulate and talk about objects in space are explored and systematically described. It is typical of Piaget's approach that the course of the investigation seems to have been, in part at least determined by purely logical considerations. Thus the reader moves from topological space through projective space into Euclidean space. Consequently the whole account has an orderliness that is often missing from child studies carried out elsewhere. On the other hand, the empiricist might complain that Piaget and Inhelder's data are used for illustrating rather than proving an essentially deductive set of theories and that the order is imposed, not discovered.

Since this line of criticism is perhaps the only one to which these admirable studies seem open, it may be considered further. To begin with, the detailed statistics now regarded as desirable in Britain and America are nowhere presented by Piaget and Inhelder. To be sure, one paragraph in Part 2 begins promisingly: "These experiments were carried out on 100 children, 21 between 4 and 6 : 6 years, 30 between 6 : 7 and 8 years, 33 between 8 and 9 : 6 years and 16 between 9 : 6 [should it be 9 : 7 ?] and 12 years", but in the subsequent text no attempt is made to relate the developmental stages in space perception to any given number of children of a particular age. It is clear, however, from the whole nature of this study that Piaget and Inhelder are primarily concerned with what follows what, and are not particularly interested in the precise age at which the different stages occur. If anyone wishes to construct a developmental quotient on the lines of the intelligence quotient, then he may do so and the present study will provide him with an invaluable starting-point; but the authors themselves have accomplished quite a different task.

Thus the methodological criticism may be in large measure discounted, and we can accept gratefully this richly detailed natural history of how our awareness of space grows from simple juxtaposition to the manipulation of perspectives and the arguments of geometry. A central theme of the whole account is the important part played in space perception by our own activities. We have inherited from John Locke and the empiricists a view of perception in which the outside world, as it were, imposed itself upon a passive organism. Almost all recent research has shown the untenability of this view, and the present study may perhaps serve to inaugurate a new and quite different approach.

To someone who has at one time wrestled with the original French text, the present translation seems to have been excellently carried out, and any difficulties that the reader may encounter derive from the complexity of the original and not from any defect in the expression.

NEW TECHNIQUES AND APPLICATIONS IN MOLECULAR SPECTROSCOPY

Molecular Spectroscopy

Edited by George Sell. (Report of a Conference organized by the Spectroscopic Panel of the Hydroarbon Research Group of the Institute of Petroleum, and held in London, 28–29 October 1954.) Pp. iii+234. (London: Institute of Petroleum, 1955.) 2*s*. net.

IT is not so very long ago that self-respecting spectroscopists frowned upon anything more omplex than a diatomic molecule. However, the apid development of the petrochemicals industry as given a great fillip to applied spectroscopy, which has become much more 'broad-minded' with regard to the size of molecules and the complexity of their mixtures that its adepts take in their stride.

Perhaps one of the first of the spectroscopists of the 'old school' who sensed the power of spectroscopic methods as a tool for developing industrial rocesses was Victor Henri, and indeed nowadays ultra-violet and infra-red methods are necessary tools of the petroleum industry and of many other branches of the chemical industry. To this the present volume bears witness. Yet beyond this it also sheds light on techniques which still have to prove their value for the field of hydrocarbons.

This book is a collection of nineteen papers which were read by invitation at a conference which the Spectroscopic Panel of the Hydrocarbon Research Group of the Institute of Petroleum held in London in 1954. The object of the conference was to bring together people for a discussion of newer techniques. In this endeavour, and in a laudable spirit of being non-parochial, the Panel succeeded in attracting contributions from workers in Britain and overseas. The papers are written by people with widely different interests and touch upon very different aspects of applied spectroscopy. It is only natural, therefore, that they vary considerably in length, depth and breadth.

It is interesting to learn that about two thousand infra-red spectrometers are in use to-day, that cæsium iodide prisms can be made from synthetic crystals to allow measurements to 54μ, and of the possibilities opened up by additively coloured alkali halide crystals as infra-red transmission filters. There is information on gratings for use in the 2–15μ region with line spacings varying from 15,000 to 2,400 lines/inch, on the pressed-disk technique for obtaining spectra of solid materials, on infra-red reflexion spectra from small crystals, on Raman spectrometry, and on infra-red emission from gases excited by a radio-frequency discharge. Gases can be heated to temperatures in excess of 5,000° C. in fewer than ten molecular collisions by the application of shock-waves. For analytical purposes, on the other hand, low-temperature work may become useful where mixtures solidify to transparent disordered glasses. What the analyst is looking forward to very much is to be able to transfer data from one instrument to another; that is, to assess true intensities from the measured spectra. He derives immediate benefit from a classification of the characteristic vibration frequencies of substituted benzenes. The amount and position of deuterium in mono-deutero-aromatics in the presence of their parent compounds can be determined by infra-red spectrometry. Oxidation plays a great part in the quality and shelf-life of many hydrocarbon products, and infra-red spectrophotometry can be beneficially employed as a yard-stick for the degree of oxidation.

Both Raman and ultra-violet spectrometry have their places in type analysis, and there is an interesting account of the determination of aromatic hydrocarbons in lubricating-oil fractions by work in the region of 1900 A. The future will show the part which the flash-photolysis technique and nuclear magnetic-resonance spectra can play in the field of hydrocarbons. There can be little doubt that fluorescence techniques are in the ascendancy. An article of about two thousand words, on the use of fluorescence for industrial analysis and examination, is a masterpiece of concise presentation. The book contains a record of the discussion to each paper, and a discussion on punched cards and the presentation of spectral data forms its concluding chapter.

Workers in the petroleum industry owe a debt of gratitude to the Institute of Petroleum for making available for reference purposes this fountain of information.

R. SCHNURMANN

Electromagnetically Enriched Isotopes and Mass Spectrometry

Edited by M. L. Smith. (Proceedings of the Conference held in the Cockcroft Hall, Harwell, 13–16 September 1955. Sponsored by the Atomic Energy Research Establishment, Harwell.) Pp. xvi+272. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1956.) 45*s*.

THE appearance of this collection of papers on enriched isotopes will be welcomed by all who are interested in this field. These papers are concerned both with the technique of electromagnetic enrichment and with the applications of the enriched isotopes. Since much of the material either has not been published before or is contained in reports of limited circulation, its collection within one volume is an important contribution to the literature of the subject.

More than half the thirty papers are concerned with problems of design in the separator itself. Since the principal factor which determines whether or not an element can be processed electromagnetically is the availability of suitable ion sources and collectors, several papers are concerned with detailed discussion of their construction and of associated chemical problems. It is interesting to note that it is now possible to process in substantial quantities the stable isotopes of nearly all the elements. Abundance measurements and mass-spectrometry are surveyed in a number of papers, and interesting contributions are included on the method of dilution analysis and on a new type of mass-spectrometer employing radio-frequency methods. Other survey papers describe typical uses of enriched isotopes and give some indication of their wide field of application. Two papers direct attention to the importance of applying enrichment techniques to radioactive isotopes.

The book is well produced and contains clear diagrams and photographs. The provision of an adequate index and the inclusion of the discussions which followed the papers add greatly to its value.

M. A. GRACE

Protoplasmatologia

Handbuch der Protoplasmaforschung. Herausgegeben von L. V. Heilbrunn und F. Weber. Band 2: Cytoplasma. *A*: Morphologie. 2: Die Submikroskopische Struktur des Cytoplasmas. Von A. Frey-Wyssling. Pp. iv+244. (Wien: Springer-Verlag, 1955.) 72*s*.

DURING the past five years the electron microscope has become the main tool for investigating cellular fine structure. This change in technique is reflected in the much greater space given in this book to electron microscope results than in the earlier work by Prof. A. Frey-Wyssling on submicroscopic morphology. The section on electron microscopy, which takes up the first half of the book, will be most useful to cell biologists. It brings together, for the first time, observations on cell structure which have been scattered through a large number of journals and discusses them in terms of both cell function and molecular morphology. There is an interesting section on the structure of the ground cytoplasm in which Prof. Frey-Wyssling points out the dangers of artefacts and illustrates them with some striking photographs of reticular structure in gelatin and Liesegang rings after osmium fixation. There are a number of good reproductions of electron micrographs, but one could wish for more.

The second half of the book is concerned with those aspects of chemistry, cell physiology and biophysics which are relevant to cellular fine structure. Perhaps the best section is that which deals with the structure of proteins and nucleic acids and describes the recent work of the X-ray crystallographers in this field.

J. M. MITCHISON

Physical Chemistry

By Prof. Walter J. Moore. Second edition. Pp. xii+633. (London and New York: Longmans, Green and Co., Ltd., 1956.) 30*s*. net.

PROF. W. J. MOORE uses the thermodynamical approach to physical chemistry, and his readers need a knowledge of advanced mathematics and the ability to apply them. The first edition (1950) was reviewed and commended in these columns (see *Nature*, 168, 577; 1951). In this, the second American, but first English, edition the author, in bringing the work up to date, has accepted friendly criticism and made numerous small improvements.

The chapters dealing with nuclear chemistry and electrochemistry, and that on the structure of molecules, have all been enlarged. Prof. Moore has extended the scope of the section on photochemistry, has removed it from Chapter 17, on kinetic energy, and has made it into a new chapter on photochemistry and radiochemistry. To the curtailed Chapter 17 he has added two new sections dealing respectively with reactions in flow systems and with the mechanisms of ionic reactions. The lists of articles and books recommended for further reading have been overhauled, brought up to date and extended. Many of the newly listed articles are from the *Journal of Chemical Education* or from the Chemical Society's *Quarterly Reviews*.

The work is recommended to those studying physical chemistry at university-level who have the necessary mathematical equipment.

G. F.

Animal Breeding

By Dr. A. L. Hagedoorn. (Agricultural and Horticultural Science Series.) Fifth edition. Pp. xix+364+21 plates. (London: Crosby Lockwood and Son, Ltd., 1954.) 18*s*. net.

PROBABLY no other book has done more than this one to stimulate practical livestock breeders and students of animal husbandry to take an acute interest in genetical principles and ideas. It is fitting that in this fifth edition, with its revisions and additions made by Dr. A. L. Hagedoorn before his death, there should be a memoir of the author by Dr. John Hammond which notes his outspoken critical approach to practical problems and controversies. For his provocative decrial of "fancy points" and show-ring standards, his robust insistence on progeny testing, and his advocacy of the nucleus system of breeding are further emphasized here.

Hagedoorn's own interests in, and practical contacts with, the breeding of large and small animals ranged widely and have once more been freely used for illustrating his main themes and provide the reader with a wealth of observations. Yet the tendency—perhaps need for his purpose—to over-simplify his interpretations of the underlying principles and his advice on breeding problems and procedures remains while the book can certainly be recommended to be read, it still cannot be accepted without reserve as the full and authoritative word on this aspect o animal production.

J. E. NICHOLS

CHEMICALLY INDUCED NEOPLASMS IN FUNGI

By Prof. P. T. THOMAS, Dr. H. J. EVANS* and D. T. HUGHES
Department of Agricultural Botany, University College of Wales, Aberystwyth

A NEOPLASM may be defined as a new growth which differs characteristically from that which occurs during normal cell reproduction and differentiation[1]. The benign and malignant neoplasms of animals have naturally, owing to their great importance, been subjected to the most intensive investigations. Unfortunately, animal material is not always favourable for fundamental studies into the factors which determine the origin of these abnormal growths. For this reason attempts have been made to use other organisms, and much useful information has been obtained from the study of tumorous malformations in higher plants[2-7].

From observations and experimental work which we have carried out on a number of fungi we now wish to indicate how this group of organisms may well be particularly favourable for elucidating certain aspects of the problem of cancerous neoplasms in animals. Fungi, unlike higher plants, contain no chlorophyll, and being heterotrophic are, like animals, dependent on nutrients synthesized by other organisms. Many of their metabolic products, for example, glycogen instead of starch, are also essentially similar to those of animals. Indeed, the whole physiology of fungi has so much in common with animals that biochemists have for a long time been using them as physiological models to study "under better controlled conditions, general biochemical reactions of animal tissues"[8].

The degree of control which can be achieved is of major importance, since it includes not only better control of environmental conditions but also of the genetical constitution of the experimental organism.

Interest in this direction was first stimulated by the work of Haddow, who compared the formation of secondary colonies in senescent bacterial cultures with the emergence of a malignant variant in the cells of ageing animal tissues[9]. Later Bausch[10] produced new forms of the yeast *Saccharomyces cerevisiae* by the action of well-known carcinogenic hydrocarbons and also by camphor, which is not known to be carcinogenic in animals. The yeast cells produced were vigorous giant-celled forms and, without cytological confirmation, it was concluded that the effect was due to polyploidy.

From a cytological study of the action of camphor on the asexual yeast *Torulopsis utilis*, Thomas concluded that the significant change in the production of vigorous giant-celled forms occurred in the cytoplasm[11,12]. Multinucleate cells were sometimes produced (Fig. 1); but these were unstable and there was evidence of a 'somatic reduction' to a stable mutant form with a normal nuclear complement and a changed cytoplasm.

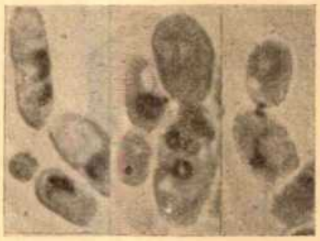

Fig. 1

From the following considerations it was concluded that there was a close analogy between the action of camphor on yeast and that of carcinogenic agents on animal cells: (1) marked increase in the concentration of nucleic acids, particularly of ribonucleic acid in the cytoplasm and nucleolus; (2) increase in the rate of cell reproduction, that is, reduction in generation time; (3) inhibition of growth during initial stages of treatment by the chemicals; (4) the chemical agents are effective only after a relatively long period of treatment. In yeast, which normally produces a new cell generation every hour or so, the mutant cells appear only after treatment for 2–3 days.

The type of change which occurs in yeast is essentially in agreement with the view that carcinogenesis involves an optimum inhibition of normal cell growth followed by an adaptation which allows the cells to continue growth[13]. Observations indicate that the chemical agent has a mitostatic effect on the yeast cell nucleus, but at the same time allows cytoplasmic activity to proceed to a new and apparently stable equilibrium.

Neoplasms are more easily recognized when the cells are organized into a tissue or into a pseudotissue as in the fructifications of the larger fungi. Fig. 2*a* illustrates a striking growth malformation produced in the cultivated mushroom *Agaricus campestris* fr. va. *bisporus*, where it has outgrown the normal pileus by at least five times. This tumorous growth is believed to have been induced by the accidental introduction of tarry fumes into a commercial mushroom house. The grower at Aberystwyth was forced to supplement the electrical heating of one of the houses by burning a mixture of coke and coal in open braziers. Between 20 and 30 per cent of the fructifications in the affected house were abnormal; but no such abnormalities were found in another, but smaller, house in which heating by electricity was adequate.

Reference to the literature showed that rather similar but less-pronounced abnormalities had been recorded for the first time in 1930 by Lambert[14]. He proposed the term 'rose-comb disease' and directed attention to its prevalence during 1930 in New York, Pennsylvania, Ohio and Missouri. From his general observations on these abnormalities he wrote as follows: "The agencies that seem most likely to be the cause of the tumours are the coal oil fumes or the fumes or oxidation products of materials containing mineral oil". Atkins, a prominent mushroom grower in Great Britain, also states that mineral oils and coal tar creosote fumes are important agents[15].

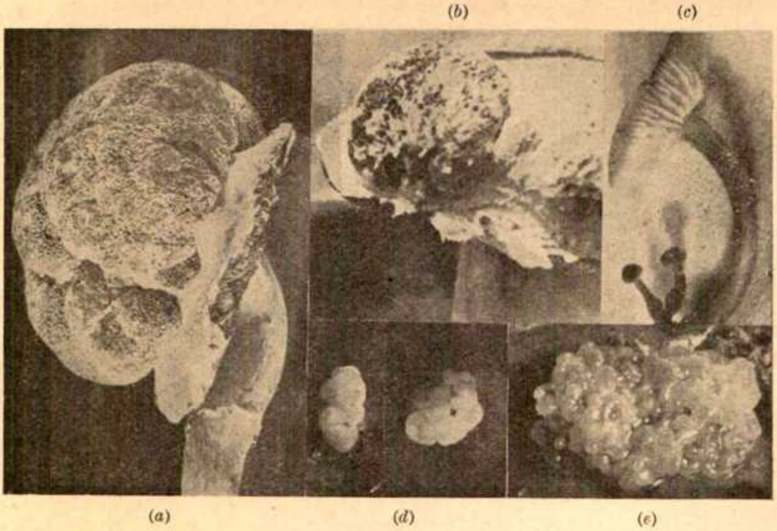

Fig. 2. *Agaric* neoplasms: *Agaricus campestris* with tumorous outgrowths of the pileus (*a*) produced in a commercial crop of mushrooms, and (*b*) induced experimentally by diesel oil vapour treatment. *Collybia velutipes* (*c*) normal fructifications after olive oil treatment. *Collybia* tumours produced after an equivalent treatment with diesel oil, (*d*) at 4 weeks, and (*e*) 8 weeks after initial treatment

One of us (H. J. E.) has carried out experiments designed to study the effects of a number of substances, under controlled conditions, on a commercial strain of the cultivated mushroom. The mushrooms were grown in 9-in. pots on a standard compost and maintained at constant temperature and humidity. Some additional experiments were conducted on mycelium grown in agar culture. A number of pure carcinogenic hydrocarbons were used; but although they had some effect on the growth of mycelium in culture they did not produce the characteristic tumorous malformations when applied to mushroom fructifications. Failure to produce any effect with these hydrocarbons may have been entirely due to technical difficulties involving, in particular, the use of solvents which were toxic to the fungus.

However, volatile mineral oils and coal-tar products could be used directly, and the amount of vapour applied was controlled. With some of these substances tumorous malformations of the type shown in Fig. 2*b* were repeatedly induced. The most striking results were obtained either by treatment with a proprietary substance containing tar acids, or with diesel oil. The latter was by far the most effective agent. Thus, in one series of experiments with diesel oil vapour, tumours were produced on 80 per cent of the mushroom fructifications, after periods of treatment ranging from three to eight days[16]. The maximum amount of tumour production was obtained after a sustained treatment with the vapour at a concentration which retarded development, but was not unduly toxic.

Tumours first appeared as protruberances of the pileus, as early as the young pin-head stage, or later when near maturity. They continued to grow even after the pileus had fully developed. Several distinct tumours could develop on a single pileus; but they often coalesced to form one large deeply lobed tumour. Sometimes, the outer tissues of a tumour differentiated into a spore-producing hymenium resembling that found in the Polyporaceae. (*cf.* Fig. 2*a* and 2*b*.)

Recently, another agaric fungus, *Collybia velutipes*, has shown certain advantages over the cultivated mushroom for experimental purposes. It is smaller in size and can be grown in large quantities in 250 c.c. flasks on a malt–agar medium. It is also found to be particularly sensitive to diesel oil, both in vapour and in liquid form. Treatment was given at the 'pin-head' stage for 14 days, after which the young tumours could be recognized (Fig. 2*d*). Further growth has been observed after up to eight weeks while still under the influence of diesel oil (Fig. 2*e*). Typically, these neoplasms have cerebiform convolutions and there is no differentiation of gill tissue. Fig. 2*c* shows normal development after an equivalent treatment with olive oil. If treatment by diesel oil is delayed until differentiation of the pileus has commenced, fruit bodies the edges of which curl up into tumorous over-growths are produced.

Cytological investigations, so far, have been largely confined to the cultivated mushroom, where comparisons between cell behaviour in normal and tumour tissue have been made[17]. Normal tissue, at the pin-head stage, is composed of closely packed, multinucleate, non-vacuolated cells, each containing an average of six to seven nuclei. Few nuclear divisions occur after the fructification has attained a diameter of about 10 mm. and further development is associated with vacuolation and increase in cell size.

Unlike the surrounding normal tissue, however, the tumours are composed of two kinds of cells, both of which contain actively dividing nuclei (Fig. 3): (i) small, non-vacuolated, multinucleate cells, with markedly basophilic cytoplasm (T_1 cells); (ii) larger vacuolated, multinucleate cells, showing less basophily of the cytoplasm (T_2 cells). In addition, intergrades between these two cell types are found.

The change from a normal to a tumorous condition involves the transformation of normally inactive pileal cells (N_1), with a comparatively low ribonucleic acid turn-over, into actively dividing basophilic T_1 cells. The T_1 cells reproduce their own type and also give rise to vacuolated, less actively dividing T_2 cells. Normal pileal tissue has an average of

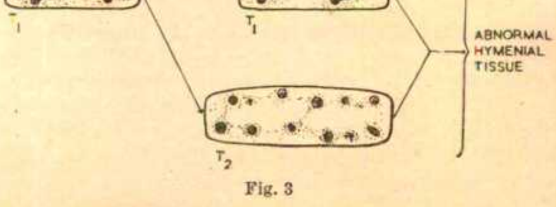

Fig. 3

$6{\cdot}44 \pm 0{\cdot}08$ nuclei per cell, whereas in the mature tumour where there is a preponderance of T_2 cells, the average number of nuclei per cell is $10{\cdot}1 \pm 0{\cdot}36$.

In addition to the increased basophily of the cytoplasm and mitotic activity of the nuclei in T cells there is hyperactivity of the nucleolus and heterochromatin. Tumour cells also show abnormal nuclear activity including endomitosis, multipolar spindles, chromosome aggregation, polyploidy, aneuploidy and micronuclei. These cytological disturbances are all characteristic of cells in animal tumours[18,19].

Our observations on a number of fungi serve to emphasize the desirability of undertaking further work on the nature of the changes that are produced by the action of various chemical agents. While fungal cells are not ideally suited for cytological study, there is little doubt that the comparison with the behaviour of cells in animal neoplasms represents something more than a mere analogy. Preliminary work on grafting neoplastic with normal tissue already indicates a promising field of research. Furthermore, the simplicity of organization of the fungi, together with their suitability for culture on synthetic media, should provide ample encouragement for biochemical studies.

We are very grateful to Prof. A. Haddow, of the Chester Beatty Research Institute, not only for his advice and encouragement, but also for supplying a number of carcinogenic hydrocarbons. Our investigations, which will be described in detail elsewhere, have been made possible by a grant from the British Empire Cancer Campaign, to which we also extend our gratitude.

EDUCATION AND PRODUCTIVITY IN UNDER-DEVELOPED AREAS

THE main theme this year of Section L (Education) of the British Association was education in the British Colonies, and, following Sir Christopher Cox's provocative presidential address, it fell to two symposia to deal in greater detail with two of the central problems involved. These were the relationship of education to productivity, and the central educational dilemma of quantity or quality. Each was the subject of a separate symposium, and Prof. F. C. Benham, of the Royal Institute of International Affairs, opened the first with a paper on "The Allocation of Resources". He pointed out how poor the British Colonies are, with an average income per head of population of only one-tenth to one-seventh of that in Britain. Like all poor countries, they are faced with a difficult choice when they have to decide whether to spend more money on education and the social services, on one hand, or on measures for economic development, on the other. Considering briefly the case for each, Prof. Benham said that many people would urge that absolute priority be given to education, for they would say that illiterates cannot play their part properly as citizens, that children's talents and personalities need to be developed, and that we need higher education to provide leaders in society and government. But in spite of this, education is only one of the claimants among the social services; there are many others, and health and housing, for example, can also make out a very strong case.

On the other hand, the arguments for giving priority to economic development are hard to resist, for unless measures are taken to raise progressively future levels of output and income, there is no escape from a low standard of living. Referring to Lord Beveridge's point that "expenditure on education is the communal investment which in the end will bring the best return", Prof. Benham emphasized that it would be wrong to compare Britain with the Colonies in this respect, for Britain, with a population of fifty million, has a public revenue of more than ten times that of the Colonies. The latter, with a population of eighty million, have an annual income of only £50 million. Moreover, the proportion of children under fifteen years of age in Britain is only 20 per cent, whereas in the Colonies it is 40 per cent.

When a Colonial government considers how best it can use its limited resources to yield the best return, there are likely to be quite a number of projects which will give a greater and a quicker return than education. Considering the matter solely from the point of view of its yield as an investment, education might well have to take a back seat. The case for it only becomes strong when it is considered on its own merits, not as an investment but as a training for life and livelihood and as a means of character-building and raising mental stature. Even so, the Colonies are a long way from their goal, for there are three times as many children in the Colonies as in Britain, and yet only one in three receives any kind of schooling. In the educational field itself, there appear to Prof. Benham to be four outstanding priorities: an adequate flow of leaders at the university-level; teacher-training adequate both in numbers and quality; certain types of technical and vocational education; and, in some Colonies, an agricultural extension service.

Turning to the problem of finance, Prof. Benham thought there were a number of possibilities which might be considered. First, a higher proportion of public expenditure could be devoted to education; secondly, more money might be raised by taxation; thirdly, public loans for education might be raised; fourthly, more external aid might be sought; fifthly, more responsibility might be placed on local authorities; sixthly, certain measures could be taken to keep down costs. After briefly considering all these possibilities, however, he did not think he could draw hopeful conclusions from any of them. In spite of all efforts, the root of the difficulty lies in the poverty of Colonial people, and this being so, he thought the only real and permanent solution is to raise their real income by speeding up their economic development.

One of Prof. Benham's priorities was then taken up by Mr. J. C. Jones, director of education of the Regent Street Polytechnic, London, who dealt with the question of "Right Perspectives in Technical Education". Mr. Jones briefly outlined the facilities which already exist for technical education at its higher levels in the Colonies, and expressed it as his personal conviction that a good, general education is essential as a background at whatever level technological education is to be undertaken. This is of even greater importance in the Colonies than in Britain, principally because of two factors—the lack there of a mechanistic background, and the stigma which attaches to manual work. A basic solution to the problems raised by these factors is a greater introduction and emphasis upon educational handicrafts at an early age in the primary school and their continuance into all forms of secondary education. Mr. Jones then went on to describe the facilities which exist in many territories for other than higher technical education and declared that, because of the existence already in most Colonies of a nucleus of technical training facilities, he sees the possibility of a simultaneous development in technical education of both long-term and short-term policies. The former must be directed to a universal system of general education in which some provision is made for pre-vocational training at a relatively early age. The second stage must be the creation of alternative forms of secondary education providing for academic and technical streams. Industry, also, must play its part by the general introduction of apprenticeship schemes wherever conditions permit. Short-term planning, he thought, must be concerned to meet a developing situation in which the increasing demands of industry have to be set against a decreasing expatriate staff. In conclusion, Mr. Jones summarized his beliefs by saying, first, that the system of technical education as applied to under-developed areas can only succeed in so far as it is organically linked to, and continues the work of, the system of general education; secondly, that a system of technical education so applied must relate its work to the whole range of industrial need and not merely to its higher levels; thirdly, that development in technical education must always represent a compromise between long- and short-term policies, one logically conceived in the light of foreseeable economic expansion, and the other concerned primarily to meet the current need. He thought we had good reason to be proud of our past record in effecting the economic, as well as the political, independence of the Colonies.

For many years there has been criticism of the effects of Western schooling in rural, under-developed areas overseas. It has been called bookish and literary and is said to produce a dislike for agriculture, a flight from the land, a distaste for manual labour and a desire to secure black-coated employment. These and other criticisms of Western schooling were discussed by Mr. P. C. C. Evans, of the University of London Institute of Education, in a paper entitled "Western Schooling and Rural Productivity". He attempted to show that, on the whole, these charges against Western schooling are ill-founded, and that it is the humanistic spirit inherent in Western civilization which creates dissatisfaction with the low standard of living associated with the land in the Colonies. This dissatisfaction is not altogether a bad thing, for it leads to new patterns of economic endeavour which in the end will lead to increased productivity. Mr. Evans pointed out how in the past the power of the school to change society in the tropics, whether for better or for worse, has been greatly exaggerated, and that this has brought much criticism upon it for effects which are, in reality, due to the whole Western contact. Even so, in order that the standard of living may be raised, and the basic values of Western civilization find fuller expression, it is necessary that schooling at all levels should be permeated with a rural idiom, which will direct pupils' endeavours, by means of a pragmatic, problem-solving approach, to deal with the urgent problems of community living.

Perhaps the most arresting, and certainly one of the most interesting, talks of the whole symposium was that given by Mr. R. K. A. Gardiner, recently director of the Gold Coast Department of Community Development, who spoke on "Fundamental Education and Economic Development". Perhaps unconsciously, all the speakers so far had appeared to give what could have been described as a European point of view; but Mr. Gardiner, an African, showed how, in some respects, our perspectives need adjustment. He referred, for example, to Prof. Benham's insistence on the scarcity of material resources, and then pointed out that the Colonies have one rich resource which is rarely given full credit—the people themselves. Their free labour, self-sacrifice and goodwill are assets of great importance in promoting improved living, and the means of tapping these is through community development. How successful the Gold Coast Department of Community Development had been in this Mr. Gardiner illustrated in a number of striking examples. Five hundred cacao-tree sprayers had been bought by the Agricultural Department to fight swollen-shoot disease; but cocoa-farmers would not buy them. The Department anticipated that it would take about five years to sell them all. It enlisted the help of the Community Development Department, and after a short campaign by the latter all the sprayers were sold in a couple of months. Again, an important road estimated to cost a very considerable sum to build had already been half-built, with the help of voluntary labour and savings, for only £100,000. But Mr. Gardiner reminded his audience that in dealing with people it must be remembered that they are not malleable material, but human beings who matter. His eloquence and simple sincerity made a fitting conclusion to a most interesting symposium.

The task of the next symposium was to discuss "The Central Educational Dilemma in Underdeveloped Territories: Quality or Quantity", and Mr. E. W. Woodhead, chief education officer for Kent, opened it with a paper entitled "The Problem of Priorities". He pointed out how the administrator in such countries will be unlikely to have at his disposal adequate resources in money, staff or materials. Again, people on the verge of self-government see priorities differently from those a long way from it. As self-government approaches, so a desire for Utopia within a limited period grows up. A new sense of urgency arises, marked by a new relationship between government and people and often an unwillingness to recognize stubborn facts of inadequate resources, insufficiently trained staff and limited experience. Unless the administrator recognizes and accepts these new attitudes, it may not be possible to moderate harmful effects and gradually to establish worth-while standards. The approach to self-government is reflected also in the changing aims and emphasis in education, which now comes to be regarded as one of the keys to self-government and to a sense of equality with Western powers. Such aims must for a time dominate the educational scene, though other aims must not, in the process, be forgotten. For no country, said Mr. Woodhead, can reach nationhood without the development of a public morality, co-operative attitudes in its citizens and a willingness to accept responsibility. These personal aims need to be retained alongside the demand for greater knowledge and improved skills.

The growth of an education service in the Colonies, continued Mr. Woodhead, seems to pass through a number of fairly clearly defined stages. First, it provides an escape for the few from reality and the hardness of life. Then comes a mass demand for education, associated with the introduction of cash-crops or the growth of industry. This is a stage dangerous for standards, and needs to be passed through as quickly as possible. Then comes the third stage, one dominated by a political emphasis and a demand for universal primary education and the development of secondary schools. For each of these stages there must clearly be different priorities in the educationist's mind. The administrator's problem now is to ensure as wise action as possible at each stage, though, in any case, he will find his plans affected by many factors beyond his control.

In the development plans of most Colonies the goal is universal primary education with such secondary and further education as will meet urgent needs. Yet the problem is always one of how to meet new educational demands with limited resources. There are few features of life in these countries which so manifestly have such political priority as the education service. This political demand often outruns the wise use of resources and the establishment of good educational standards. The administrator is pressed, on one hand, to go ahead by the political situation, and, on the other, he is held back by economic considerations which are sometimes ignored by newly independent peoples. The chief challenge comes from such places as the Gold Coast, Nigeria and Malaya, where the pressure of the demand for education is in danger of submerging for a time the quality of the work undertaken.

Mr. Woodhead then reviewed briefly what seemed to him important priorities at each educational level. Something could be done to safeguard priorities in primary education by avoiding a complete dispersal of trained staff and by retaining a few good schools to serve as the guardians of standards. At the secondary school stage he stressed the need for alternative provision to grammar school education. Here again the maintenance of good standards lies in the hands of a few schools. These good standards, he thought, should be high on the list of priorities, especially since secondary education must for a long time be selective rather than universally available. The highest priority of all he would accord to teacher-training, for the preparation of really good teachers is the spearhead of educational progress. In dealing with educational administration and personnel, Mr. Woodhead stressed that two important priorities affecting standards and quality are the administrative framework and the adequacy and suitability of its personnel. In the former there is an important part for the voluntary agencies, private schools and the development of local authorities. Inspection and supervision also must be improved if minimum standards are to be maintained.

In conclusion, Mr. Woodhead indicated what are to him a number of keys to quality. The responsibility for both quality and quantity must rest with the government of the territory. Care must be taken when building on inadequate foundations in primary and secondary schools in preparation for sixth forms, universities and teacher-training. The key points for the preservation of quality of work and development are the grammar school and the training college. Where choice exists, emphasis must always be put on persons of quality, whether officer, teacher or child. He thought that a few really good schools and institutions for further education should be developed in order that these might leaven the whole educational service. Every effort should be made to recruit local officers with suitable training, though expatriates should be retained where necessary in order that the best experience of the past might be available in new situations.

The problem of building secondary education on insecure foundations under pressure from a quickly developing higher educational system was the theme of a talk by Sir James Robertson, rector of Aberdeen Grammar School, when he spoke on "The Demand for Higher Education". The strain on secondary education, said Sir James, comes chiefly from the fact that it is sandwiched between primary education, on one hand, and the universities on the other. He referred to the limiting factors mentioned by earlier speakers in connexion with under-developed countries —the smallness of the resources available and the stubbornness of local educational demands. At the moment the latter can conceive of secondary education only in terms of the British grammar school, and there is a tremendous demand for formal British education because it leads to enhanced personal status and advancement. But the provision for secondary education is very small. In the Gold Coast, for example, only 2 per cent of the school population is in secondary schools, and this is a country well advanced towards self-determination. Sir James sees a number of obstacles in the way of efficient secondary education—obstacles such as insufficient preparation at the primary stage, the immense gap between local conditions and Western civilization, and the great difficulty of crossing from vernacular literacy to a facility in the English language. All these are weaknesses of the primary school; but they reappear in acute form in the secondary school and lead to a situation where pupils know words but not realities, where speech becomes vague and abstract, and where an obsession develops for examination results.

In addition to these educational problems, there are the forces of nationalism and independence, which force the pace by demanding more training college staff and quicker replacement of Europeans by local people in the education service, and which lead to compulsive demands from university and technical colleges for more students. The British have written one of the great chapters in their Colonial story in setting up the new university colleges; but in some ways they have to pay the price, for national pride and aspirations are not satisfied with the meagre provision for higher education that is warranted in view of the poor schools. These latter could do with a period of patient quiet to develop; but, as it is, good teachers who could not be spared had been diverted to sixth-form work. In the end, this may prove a good thing, for sometimes it pays to be stretched educationally, and the schools will be compensated by receiving back a stream of good teachers. But for the period ahead in the development of secondary education, Sir James said that two things are necessary: schools must keep up standards in their lower forms and improve their English, and, if a rapid expansion of secondary education comes, good staffs must not be dispersed. A few good schools must be kept going while standards are being raised elsewhere.

Miss F. Gwilliam, assistant educational adviser to the Secretary of State for the Colonies, then spoke on "The Challenge to Teacher-Training". She asked three questions: Who are the teachers, what standards are they trying to preserve, and how are they meeting the challenge? The teachers themselves, said Miss Gwilliam, have greatly varying backgrounds and qualifications, and often they were of many nationalities. There are Austrian nuns, American missionaries, teachers from Britain who have gone out through the Overseas Appointments Bureau, the personnel of the Colonial Education Service and the local teachers themselves. All these, said Miss Gwilliam, are the teachers. The standards they are seeking to preserve, she thought, are of four sorts—academic, personal, professional and civic standards—and to maintain and improve them constitutes the challenge to teacher-training. In the different territories of the British Colonies this challenge is being met in a number of ways: local training colleges are being built in increasing numbers, scholarship funds are being provided to send students to Britain for training, and 'on-the-spot' vacation courses are being run for practising teachers. The teachers themselves are taking full advantage of these facilities, and in Cyprus, for example, 80 per cent of primary school teachers take part in unpaid, voluntary vacation courses. The in-service training schemes of the Gold Coast and the Malayan training colleges in Britain are other outstanding examples of the way in which the challenge is being met. Behind all these efforts, said Miss Gwilliam, lies the educational resources of Britain in inspiration, advice and help.

The symposium was brought to an end by Mr. Philip Sherlock, vice-principal of the University College of the West Indies, who spoke on "National Aspirations". Speaking with great eloquence and clarity, Mr. Sherlock, himself a West Indian, reminded his audience that Britain had long had a well-developed sense of nationhood. This the West Indies lacks. The great task there is to bring together a great variety of strains and races and to build from them a common nation. They have to fashion a new society, unlike the Gold Coast and Nigeria, who are seeking to rebuild an old one. It is in this task of nation-building that the contribution of the West Indies to the world and human understanding lies, for to do this successfully means a great emphasis on human relationships, and perhaps in this the West Indies may have something to offer others.

Mr. Sherlock paid great tribute to Britain for its help and foresight in setting up the new University College of the West Indies, for this, he said, is basic to the whole task they have in hand. The West Indies and the United Kingdom now stand as partners in the great enterprise of finding new patterns of social development. But this, he emphasized, is not a one-way process. Both sides will profit. The West Indies wants from Britain advice on an expanding secondary school system, on teacher-training, library services and other matters, and in return Britain might profit from the lessons learnt in what is a tremendous, dynamic move forward by the peoples of the Caribbean.

After each symposium there was a discussion in which the audience participated. Contributions were made by county education officers, professors of education, training college staff and local teachers, all of whom expressed the hope that there would be, in the future, even greater collaboration between Britain and the oversea territories in the task of promoting the latter's educational advancement.

P. C. C. EVANS

PHYSIOLOGY IN THE POLAR REGIONS

DURING the meeting at Sheffield of the British Association, Section I (Physiology) arranged a session on September 4 on "Polar Physiology".

The degree of physiological adaptation to cold by man is still an unsettled problem. Although there is convincing evidence that laboratory animals can be so acclimatized that they will survive at temperatures which are lethal to control animals, chronic physiological changes in man as a result of exposure to cold have not been clearly established.

Many studies have been made in climatic chambers, in which men can stay for relatively prolonged periods in a controlled environment. Changes have been looked for in the rate of body cooling, alterations of skin temperature, changes in metabolic rate, time of onset of shivering, alteration in the peripheral blood flow and shifts of the blood volume. There has been a number of reports indicating some change in one or more of these parameters as a result of repeated exposure; but there have also been many negative reports. One of the practical difficulties of experiments in climatic chambers is to persuade subjects to stay in such chambers for long periods. There are indications that some significant physiological changes develop slowly over a period of many weeks or months. It is for this reason that observations have been sought on polar explorers, who spend one to two years at high latitudes. Many of the members of polar expeditions are trained scientists and can make accurate and systematic observations on themselves. Detailed investigations of the subjects can also be made before and after prolonged sojourn in the polar regions, in laboratories in the country of origin.

Apart from low temperatures, another environmental characteristic of polar regions is of interest to physiologists. In high latitudes, the cycle of light and darkness varies greatly during the year, with approximately three months winter darkness and three months summer daylight. There are many biological diurnal rhythms, and it is of considerable interest to know how these rhythms in man may be affected by alteration in the pattern of day and night.

Dr. Harold Lewis, who accompanied the British North Greenland Expedition of 1952–54 as physiologist, showed a film illustrating some of the physiological problems encountered, and which demonstrated very vividly the effects of light and darkness. He also read a paper entitled "Sleep and Wakefulness Patterns in Men on a Polar Expedition". Records were kept by the members of the expedition of the hours spent in sleep each day. During the autumn and the spring, the patterns of sleep resembled those commonly observed in temperate countries. The majority went to bed between 10 p.m. and midnight and got up some eight hours later. When the sun disappeared for the long winter night, the pattern became increasingly disrupted, and the different individuals were going to bed or getting up at all hours. There was never a time when someone was not in bed or someone out of bed. Sleep was no longer restricted to the hours between 10 p.m. and 8 a.m. The intervals between periods of sleep varied greatly and so did the length of each period of sleep. A similar disruption of sleep was observed during the months of continuous daylight. These changes were observed in both years during which the expedition was in North Greenland. There did not appear to be any tendency for adaptation to the day–night pattern.

There are a number of interesting questions on sleep behaviour which can be asked as a result of these observations. Particularly during the winter months when opportunities for field-work were severely restricted, there was relatively little to do. There was no social compulsion to get out of bed at any particular hour, and opportunities for sleep were to all intents unlimited. The situation was analogous to that of 'demand' feeding in infants. Where records of the number of hours spent in sleep have been kept, in Britain and in the United States, the average is found to be approximately eight out of the twenty-four. On the North Greenland Expedition the number of hours of sleep averaged 7·9, and there was little difference for any month of the year. So it would appear that eight hours of sleep a day does represent a normal demand. There was no evidence that the incidence of light or darkness affected this average duration of sleep, although there was possibly an increased variation in the number of hours of sleep in twenty-four hours during the winter months.

Dr. Mary Lobban followed with a paper, "Studies on Physiological Diurnal Rhythms in Polar Regions". In the summers of 1953 and 1955, two expeditions went from Cambridge to Spitsbergen to study the effects of prolonged periods of life with abnormal time routines upon physiological diurnal rhythms in man. In Spitsbergen the climatic conditions are such that a very high latitude can be reached with comparative ease in the summer months, and human subjects can be maintained there for considerable periods of time in isolation and under conditions of almost constant daylight and environmental temperature.

In 1953 eight subjects lived for six weeks on a 2-hr. 'day', while in 1955 one group of seven subjects ved on a 21-hr. 'day' and another group of five ubjects lived on a 27-hr. 'day' for a similar period. n all three groups, urine samples were collected from the subjects at frequent intervals on experimental recording 'days' and a complete study was made of their diurnal excretory rhythms throughout the experimental period. On these recording 'days', diet, fluid intake and all physical activities were carefully controlled. During the 1955 expedition the diurnal variations in body temperature were also recorded.

From the results obtained on the two expeditions it would seem that rapid adaptation of the urinary rhythm to an abnormal time routine is an uncommon occurrence. In nearly all the subjects on all three time-scales, the intrinsic 24-hr. excretory rhythm persisted to a greater or lesser degree, and in some it was maintained unimpaired for the whole duration of the experiment. Subjects who failed to become adapted to the environmental time routine showed signs of stress, particularly at those times when their excretory rhythms became greatly disorganized. In at least three subjects on the 1955 expedition, the disorganization of their excretory rhythms was peculiarly complex, in that a complete dissociation occurred between the rhythms of the excretion of water and of potassium. Further evidence for the dissociation of physiological rhythms was provided by the body-temperature recordings; in all subjects on both 21-hr. and 27-hr. routines, the body-temperature rhythm appeared to become adapted rapidly and completely to the environmental routine, irrespective of the degree of adaptation manifested by the excretory rhythms.

These experiments provide evidence for the persistence of the intrinsic, 24-hr. rhythm of kidney function in some human subjects; they also indicate that the mechanism which controls the normal diurnal variations in body temperature is not the same as that controlling the excretory rhythm.

Dr. J. P. Masterton, who was the medical officer on the British North Greenland Expedition and collaborated with Dr Lewis in the physiological work, read a paper on "Nutrition and Energy Expenditure during a Polar Expedition".

There is still a lively controversy on the effects of temperature on food intake and food requirements. Investigations during the Second World War showed that the consumption of food by American soldiers rose as the temperature fell, and there appeared to be an inverse linear relationship between the two. Recent investigations of the diet of Eskimo and other inhabitants of arctic Canada and Alaska show that the calorie intake in cold countries may be little different from that in temperate countries. There have been only a few measurements made of energy expenditure in polar regions, so knowledge of food requirements is largely based on the accumulated experience of different expeditions.

Dr. Masterton measured the food intake of four men during the winter when they were living in the base hut. The daily individual intake was recorded for two periods of one week each, with a month's interval between the two weeks. A diary was kept of the activities of the subjects during these experimental periods, and from this, together with the measured basal metabolic rate, the energy expenditure was computed. There were wide daily variations both of expenditure and intake during this period, the range being 1,990–3,760 Calories consumed, with a mean value of 3,908. Expenditure varied from 2,220 to 5,890 Calories, the average being 3,510.

According to these calculations, the men were in positive food balance, and this finding is supported by the result of the measurements of body-weight, which showed substantial increases during the winter. Food was not limited at the base hut, and substantial snacks could be prepared by individuals apart from the regular meals.

The same subjects were out sledging for prolonged periods during the spring, and measurements were made of intake and expenditure during ten days. A high-calorie ration was provided; but the possibility of supplementing this was limited. The intake was much more constant, the range of forty observations being 4,000–5,500 Calories, with a mean of 4,800. Expenditure, on the contrary, varied much more, as weather on occasions prevented sledging, and a whole day would have to be spent in the tent; the range was 2,230–7,670 with a mean of 4,950. There was loss of weight during these long sledging journeys, which is consistent with the estimated negative calorie balance.

Although it is not possible on the basis of these results to be dogmatic about the effects of cold on food intake, they form a valuable basis for future work. A mean daily calorie expenditure of nearly 5,000 Calories represents very hard work, and it will be of great interest to have accurate metabolic measurements.

A food intake of 3,900 Calories in the base hut is also high, although not so high as some predictions of the effect of cold might indicate.

Dr. Masterton started his measurements because it was noted that the huskies ate human fæces voraciously in spite of the apparently adequate diet provided for them. It was considered possible that there might be a considerable excretion of fat in the fæces, in view of the high fat content of the diet both at base and while sledging. Analysis of the fæces showed, however, that the fat content was low, so the reason for this dietary habit of the dogs remains unexplained. There are a number of problems concerning the nutrition and energy expenditure of huskies which have not been previously studied. Mr. Julian Taylor described briefly some of the work he had done during the past two years while he was a member of the Falkland Islands Dependencies Survey, and specially studied dog physiology. He calculated energy expenditure during sledging by measuring the pull exerted, and recorded body-weight changes together with the food intake. Although the food consumption was high, being of the order of 2,800–3,000 Calories per day, there was considerable loss of weight during long journeys. Mr. Taylor estimated that the energy output was of the order of 4,000 Calories per day. This is a very large figure, as the weight of the dogs was of the order of 90 lb. Examination of the fæces showed that there was relatively poor utilization of the diet. Mr. Taylor emphasized the need for further studies on the physiology of husky dogs, and pointed out that dog teams still play an essential part in polar travel.

Studies on acclimatization to cold were presented by Dr. Paul Massey, who acted as medical officer for the Falkland Islands Dependencies Survey. He used Mackworth's *V* test for measuring changes in local acclimatization to cold in the fingers. By means of this test, the tactile discrimination of the finger is measured before and after the standard exposure to cold, and Dr. Mackworth has shown that there is a diminishing loss of finger numbness during repeated exposure of subjects in a cold chamber. Dr. Massey was able to study members of the Falkland Islands Dependencies Survey on Graham Land, some of whom were newcomers and others who had already spent a year or more in the Antarctic. Initially there was a marked difference between the two groups, those with antarctic experience having a much smaller loss of sensation in the finger after exposure to cold. This difference diminished during the first six weeks in Graham Land, and thereafter there was little difference between the two groups.

These results indicate that there is a fairly rapid local adaptation to cold. However, Dr. Massey believes there is probably a longer-term adaptation, as on several occasions there was mild frostbite of the exposed fingers during the test. These, however, only occurred in the newcomers.

Dr. Allan Rogers, who has been appointed as physiologist and medical officer to the Trans-Antarctic Expedition, 1955–58, described the programme of physiological research which he plans to carry out on the Expedition. He pointed out that this is a unique opportunity for physiological investigations, as the journey itself will probably occupy some four months and involve a considerable degree of exposure to cold. The work to be done on this expedition is a direct continuation of physiological work carried out on the British North Greenland Expedition, and has been planned with the help of the Medical Research Council. It is not possible to carry out elaborate experiments, for the working conditions during the crossing will be difficult, and the physiologist will also act as medical officer and dentist and will have the responsibility of veterinary work for dog teams. No heavy or bulky apparatus can be taken, as food and fuel will occupy almost the whole of the available space during the crossing.

In view of the practical importance and theoretical interest of the effect of cold on food intake and energy expenditure, the main investigation on the fifteen members of the Expedition will be an attempt to make an energy balance. Dr. Rogers will be taking with him an instrument designed by H. S. Wolff—the integrating motor pneumotachograph—for the measurement of oxygen consumption. The advantage of this apparatus is that it can be worn for long periods of time without interfering with the activity of the subject, and it has been so modified that it can be used at low temperatures. It is hoped that the members of the Expedition will be able to keep detailed diaries recording their activities, including hours of sleep, and also of clothing worn. Such diaries have been kept on other expeditions, and although the information so far obtained is not sufficiently systematic, it does indicate that the amount of clothing worn in the cold diminishes with prolonged life at high latitudes. This is certainly suggestive of adaptation to cold.

The experience which has been gained in the past few years by members of the Medical Research Council in developing physiological work on expeditions has shown that there are three important points to be realized: (1) that physiology must be an accepted object of the expedition; this is particularly important, as at this stage systematic observations at frequent intervals are necessary; (2) such observations should be carried out or supervised by a physiologist, or a medical officer with some special training in physiology; (3) only simple observations or experiments should be attempted; these principles were well illustrated in the case of the Trans-Antarctic Expedition, in which physiology is, thanks to the enthusiasm of Dr. V. Fuchs, an accepted object of the Expedition, and an experienced physiologist has been appointed. O. G. EDHOLM

METAL FATIGUE IN THEORY AND DESIGN

By Dr. A. J. KENNEDY

British Iron and Steel Research Association, London, S.W.11

AN international conference on the fatigue of metals, sponsored by the Institution of Mechanical Engineers, in co-operation with the American Society of Mechanical Engineers, was held in London during September 10–14. Some eighty papers were presented, covering the whole range of interests in fatigue, both academic and technological. Contributions were made by authors from Australia, France, Germany, Japan and the U.S.S.R., as well as from the United States and Great Britain. More than six hundred scientists and engineers attended the meetings, and the discussions on the papers brought in contributors from many more countries. The papers are to be read again in New York at a second conference during November 28–30, and the whole of the proceedings, with the discussions from both centres, is to be published afterwards in a single volume. The enterprise is the most ambitious of its kind yet attempted, and occurs at a significant stage in the development of fatigue theory and machine design.

The conference covered so wide a range of research that no short report could do justice to the detailed information presented. Certain general observations on the subject can, however, be made, prompted and shaped, as it were, by the discussions which took place. These can be very usefully viewed against the background of past development, and suggest the way in which the subject may evolve in the future.

Fatigue in metals, and in solids generally, has been plagued with an inappropriate title and an inaccurate popular press. As a subject it is really quite old. The early observations, being far in advance of understanding of the solid state, gave rise to a terminology, and even a philosophy, which have hampered scientific thinking ever since. Criticisms are repeatedly lavished on the scientists for their failure to communicate ideas and findings in a way which all can understand. This proves a most admirable exercise, but it seems hard that the scientist, who deals with difficult and often esoteric mathematical concepts, should be selected as the plain man's scapegoat, good material though he may be. He might reasonably, at times, ask for a little less plainness at the other end.

In the case of fatigue, however, much of the responsibility for the popular misconceptions rests squarely on the scientific exponents. Intentionally or otherwise, the doubts and dissensions within the subject are popularly interpreted as revealing a general ignorance of its nature, cause and effects. Recent failures in aircraft appeared to give point to this. In fact, there is, in certain directions, a surfeit of information on the subject; test data have been loading down the technical press for years, following the much careful and laborious experiment that has been undertaken in establishing the importance of a variety of practical factors. The general answer to the popular legend that metal fatigue is as prevalent and as little understood as the common cold is supplied by every aircraft, or every engine, which does not fail during its design life. These are the successful products of anti-fatigue methods, for which engineering science should be given every credit. Of course, there is uncertainty about the fundamental nature of fatigue. But the theories of the mechanical properties of metals generally are still very conjectural, and it needs to be remembered that the microscopic mechanics of the solid state have turned out to be far more difficult to understand than its chemistry or its metallurgy, in the structural-compositional sense. Problems involving, essentially, the structures of atoms, and the differences between such structures, supremely difficult though these may be, have gone forward more readily than those involving the forces between atoms in aggregates, whether solid or liquid. It was, of course, in order to deal with these difficulties that the idea of a crystal imperfection, or dislocation, was first introduced. While this idea fitted at once certain observations on the nature of slip in single crystals, it is only during very recent times, indeed during the past ten years, that the theory can be said to have established itself as a fruitful study in its own right. It now has a number of successes to its credit, of various kinds; but these are recent and involve fairly simple systems, such as, for example, pure single crystals under restricted conditions of stress and temperature. It is therefore unreasonable to expect that such an involved problem as the behaviour of complex alloys under complex stresses and conditions should be particularly well understood, or even that some single answer exists.

This latter assumption, that all failures under alternating stresses can be lumped together as the consequence of some unique process called fatigue, needs to be strongly dispelled. Useful mechanical metals have a complicated structure, and are subjected to a complicated thermal and stress treatment. They are made up of regions of differing composition, some of which may in turn possess a form of internal substructure. Each particular type of region, in isolation, may have quite different characteristics of deformation from the others, and the boundaries between such regions are also mechanically very different.

Nor are the internal stresses uniform. On the atomic scale, a number of mechanisms can occur in such aggregates: structural transformations of various types, diffusion, recrystallization, ageing, recovery, slip, polygonization, relative movements of boundaries, and so on. The operation of these mechanisms is frequently markedly directional, that is, a general anisotropy exists. At certain points quite distinctive changes may occur under alternating stresses characterized by an apparent concentration of plastic strain. In some alloys, it is interesting that an actual extrusion of material may occur at the slip band. Ultimately it is possible for small cracks to form at such sites, and some of these will be propagated, possibly to failure.

There are, then, two phases in the development of fatigue. First, the process of crack formation, and secondly that of crack propagation. It can be demonstrated that the crack usually appears at points of high local slip; but the development of such a crack must obviously depend in some way upon all the other processes taking place. Frequently all these processes are taken collectively to constitute what is termed fatigue. On the basis of present knowledge, this seems unnecessary and misguided. The fact is that a number of processes occur, and the partition of the stress energy between these depends greatly on such factors as stress, frequency and temperature, on the geometry of the system; and indeed on the chance arrangement of the constituents of the structure. It may be that future research will show that no special or singular mechanisms are required to explain crack formation by fatigue, but only the extension of others already recognized and established. At present the question is an open one. In any event, it will be evident from what has been said that, although we still have to explain how cracks may be formed in the slip-bands of crystals under alternating stresses, and to account for the differing nature of the local deformation as compared with uni-directional stressing, a number of possible modes of crack formation may arise in a complex alloy, giving rise to cracks at quite different sites under different conditions. Some discipline in our thinking is here much needed, for the idea of some single basic mechanism is deeply rooted. It is strange that this should be so, for we do not attempt to force the observations in other fields, such as those of brittle fracture, creep and ageing, into a single-mechanism explanation.

Once formed, and depending on the stress pattern and the nature of the material, a crack may be propagated. We might again well ask why this final phase should also automatically be brought together under the same general heading of fatigue. Cracks can be introduced in other ways, by quenching for example, and their propagation need have nothing whatever to do with the fatigue process as we imagine it. Some caution is necessary here, because the propagation is itself obviously dependent on the nature of the material traversed by the cracks, and it may be that the development of what might be termed the genuine fatigue process reduces the overall ductility and hence speeds the crack propagation. It is dangerously easy, then, to label all crack-forming processes, such as those that occur during corrosion, as fatigue, and hence to lose the significance that should be attached to the term.

In general, then, it seems that too much has been brought together under the title of fatigue, and that as a consequence the fundamental problem has become obscured. The problem remains, simply, why a fracture can occur in a pure single crystal (that is, in a regular lattice) under alternating stresses of a value which would not lead to failure if applied uni-directionally. The physicists seem reasonably agreed among themselves that dislocation theory can supply the answer. As it stands, the theory is now capable of demonstrating how vacancies may be generated by moving dislocations, and how these vacancies may bring about the observed increase in the speed of recovery from any residual straining. So far as the formation of an incipient crack is concerned, the collection of vacancies into clusters is taken to be the essential operation, and a mechanism for this has been proposed. No one would quarrel greatly with the general dynamics of the process as set out, and it is only fair that the theory should be allowed to prove its points, where relevant, by drawing on results, established elsewhere, of a rather different character. The theory may, in other words, establish a working model before it is fitted up around the fatigue problem, and this is indeed what has happened.

The engineers, for their part, can scarcely be blamed for being unconvinced by these tactics. Much of the theory they have necessarily to take on trust, and they feel that it is no solution simply to select from the several dislocation and vacancy mechanisms which are theoretically possible the one that best fits the facts. A much more critical experimental approach is required to demonstrate why a certain sequence of events takes place rather than another. To establish this it may be necessary to cast the experimental net much wider, and to bring in other properties, an understanding of which is already more firmly grounded. Electrical properties, particularly under conditions of extreme temperature, may be useful in affording such cross-links and in thus strengthening the whole theoretical structure. Generally, engineering has been little helped in its day-to-day problems by the more fundamental physical research. This is in many ways understandable, once the scale of the difficulties is appreciated. What is much more difficult to justify is the slight statistical treatment which the problem has attracted. Even if causes are difficult to sort out, the effects, whatever they may be, ought to provide plenty of good material for statistical analysis. There has in fact been work on these lines, and very excellent some of it is; but the infiltration of the methods into the design field, and the replacement of outdated design factors, is long overdue.

We have to admit that engineering advance, in the face of such difficulties as that of fatigue, has been gained largely by the application of what might be called the classical principles of design. More and more ingenuity has been required as the operating conditions have increased in severity, and some short relief has been obtained by the development of new high-temperature high-strength alloys. On the whole, the traditional methods of testing, coupled with established principles of stress relief, have enabled technological practice to keep up with the demands made upon it. There are, however, no large factors left in the equations. Even where some distinctive improvement in the properties of metals may be anticipated, it is quite certain that this will be quickly swallowed up by an immediate raising of design specifications. Fatigue, then, will always be with us. Supersonic machines, rockets and high-temperature gas turbines are already a reality, but their performance is below, well below, that required of them in the future. The conditions to which they will most certainly be subjected will not only be severe in themselves, but will also provide a combination of stress and temperature conditions under which fatigue, as a single factor, will be of no interest whatever. The important problem will be the survival of machines as a whole, under the complex working conditions imposed. This means their survival under repeated cycles of thermal shock, fatigue and creep, together with any other processes, such as corrosion, which may arise, the actual history being made up of both regular and random components. Although it is generally agreed that full-scale tests on major assemblies (such as aircraft) are here to stay, despite the cost, it seems worth remembering that in the case of high-speed flight the working conditions may not be reproducible at all in test form.

We are, then, confronted with a situation which differs from the past not merely in the degree of the problems faced, but in their quite revolutionary nature as well. We now have to design for change in machines, knowing that they will change and knowing that they will fail. The material design no longer demands simply knowledge of a set of static factors, but requires information on dynamic processes with statistical characteristics. The traditional methods will certainly go on indefinitely fulfilling their purpose in many fields, and they will improve; but if the materials barrier, as it may be called, is to be broken, a quite new philosophy of design is required. Whatever may develop in the future, it is certain that a mere scaling-up of the test resources, a continued amassing of data on individual properties, and a hand-to-mouth selection of material will be inadequate, however good the basic design may be. At present, not even the faintest framework of a solution exists; but there is a growing awareness of the need for some part of science and engineering to concern itself with the possibilities of quite new methods of design, particularly in the selection of materials. Such studies cannot be made without getting well away from particular problems of detail and seeing the full implications of the changes as they affect the methods of testing, the nature of the test data, the extraction of empirical factors and the use of such factors in actual design. Complex testing, so far as both stress and temperature are concerned, seems likely to replace much of the single-property fixed-conditions testing at present undertaken. The assembly of the data into a suitable usable form is bound to be fraught with great difficulties. But computing and data-processing techniques have transformed similar situations elsewhere, and encourage hopes of some success in this direction as well.

We may sum up somewhat as follows. Fundamental science needs to order its ideas on the processes which occur in metals under alternating stresses, and to be more rigorous in the distinctions drawn between fatigue and other parallel processes. The theories, though superficially sound, are facile and lack the conviction which only critical experiment can give them. The bulk of applied work on fatigue continues very successfully, according to established principles, and one by one the numerous engineering factors are being run through. There is an improved agreement between different centres of research following the better design of test machines and the recognition of differences between them, but there is a real need for an infusion of statistical theory. For the future, engineering design needs to be supplemented (not replaced) by a quite different approach involving new and, at present, unknown methods, in which fatigue takes its place as one of several interacting processes which combine to bring about, inevitably, a failure of the machine.

Conferences on the scale of the one recently held in London involve a prodigious amount of work and planning, both technical and administrative, and something more than a formal acknowledgment to the bodies concerned is required. The quality of the organization does all concerned great credit, and due to their efforts a real and effective contribution has been made to the subject. The final proceedings, when published, will be on a scale quite unlike anything attempted previously, and will surely in time become established as a major work of reference.

OBITUARY

Prof. John Garstang

John Garstang was born in 1876 at Blackburn, where his father, Dr. Walter Garstang, was a well-known physician. After leaving Blackburn Grammar School, he went to Jesus College, Oxford, with a mathematical scholarship, and graduated in 1899. While still an undergraduate his interest in archæology had been awakened, and from 1897 for some nine or ten years he undertook research and excavations at various sites of Roman Britain, particularly at Ribchester, Melandra Castle, Richborough and Brough.

His first visit to Egypt was in the winter of 1900, when he excavated at Mahasna and Bet Khallaf for the Egypt Research Account. In the following winter, supported by friends in Liverpool, he excavated on his own account in the same district. By this time he had been introduced to University circles in Liverpool, and in 1902 he was appointed honorary reader in Egyptian archæology in the University of Liverpool. During this and the following years Garstang campaigned tirelessly to stimulate interest in archæology in Liverpool. These were the years when the University was about to obtain its charter and his appeals were not ignored, for an influential group of Liverpool citizens was specially interested in ensuring that the new University should be established on broad lines. It was almost entirely due to his efforts that a sum of £10,000 was raised, and thus by 1904 premises had been secured, staff recruited, and the Liverpool Institute of Archæology was inaugurated. It was Garstang who conceived and planned the Institute, it was he who made it possible, he was its honorary secretary, and retained that office for more than forty years until the independent existence of the Institute ceased with its incorporation in the University School of Archæology and Oriental Studies. In 1907 he was appointed John Rankin professor of the methods and practice of archæology in the University of Liverpool, and held the chair until his retirement in 1941.

Although each year he did a certain amount of teaching and lecturing in Liverpool, his principal interest was in excavation. His energy was immense, and every year until 1914 saw him excavating at one or more sites in the Near East. The list of sites is formidable: Beni Hasan (1902–4), Naqada, Hierakonpolis, Edfu (Hissaia) and Nubia (1904–6), Abydos (1906–9), and Meroe in the Sudan (1909–14). At Meroe he conducted the first excavations on the site and uncovered a very large section of the enormous city. Most of the results of these excavations are still unpublished; but sufficient of his records has survived to encourage the hope that in the near future it will be possible to publish reasonably full details of his results.

During these busy years Garstang found time in 1907 to make a journey of survey and exploration across Asia Minor. This journey was to lead to an eventual widening and reorientation of his archæological interests. Apart from his own excavations at Sakje Geuzi in 1908 and 1911, in 1910 he published his book "The Land of the Hittites", which, together with its modernized successor "The Hittite Empire" (1929), was for many years the standard introduction to the subject.

In 1920, after a year as archæological adviser in Palestine, he became director of the British School of Archæology in Jerusalem, and the first director of the Palestine Antiquities Department. The creation and organization of that Department and of the Palestine Museum were virtually his own work, and showed his genius for organization at its best. Between 1929 and 1935 he directed excavations at Jericho: though some of his more optimistic claims, and still more those of over-enthusiastic supporters, are now no longer generally accepted, his work at Jericho greatly extended our previous knowledge and yielded results the importance of which cannot be disputed.

In 1936, thanks to a generous grant from Mr. Francis Neilson, he became director of the Neilson Expedition to the Near East. After a preliminary survey in Cilicia in 1936, during 1936–39 and again in 1947–48 he excavated the important site of Mersin in Cilicia. It was during his last campaign at Mersin that he was able to conduct the negotiations that led to the foundation of the British Institute of Archæology in Ankara. When the Institute was opened in 1948 he was appointed its first director, and in the following year he became its president, holding that office until his death. He died at Beirut on September 12, barely two days after his last visit to Mersin, where he had fulfilled his cherished wish to see once more the last site that he had discovered, and had addressed there a distinguished gathering.

Garstang was not a great academic figure and he built up no school of students; he was always the practical man and field-worker. He was a pioneer in many fields of archæological research. He had to an extraordinary degree a flair for discovering the good site, and once he had found that site there were few who could excel him in stimulating and sustaining general interest in the work. He had an instinctive understanding of how to appeal to the public, and his field-records and photographs show how always the propaganda side of his work was ever present in his mind. Most of his excavations, conducted in the name of the Liverpool Institute of Archæology, were carried out with the slightest of financial support: it was his gift for publicity, plus personality and untiring drive, together with loyal and generous supporters mainly in Liverpool, that year by year enabled him to open and explore new fields. It is not so much as an excavator but as an organizer that his name will live. The man whose vision and genius created organizations so diverse and so productive as the Liverpool Institute of Archæology, the Palestine Antiquities Department, and the British School of Archæology in Ankara has made a permanent contribution to archæological studies in the Near East.

H. W. FAIRMAN

NEWS and VIEWS

Prof. Charles Singer: Eightieth Birthday

CHARLES SINGER, historian of medicine and science, celebrated his eightieth birthday on November 2. Prof. Singer can look back on a life of striving and of achievement. His historical studies grew out of his clinical and research work. It is now fifty-one years since, returning from an expedition to Abyssinia, where he had medical and biological experience which many young men must have envied, he published his first clinical paper. There followed years of clinical work and of laboratory research, especially on gastric carcinoma. In the same week in which Fibiger announced the discovery of the parasite for which he was awarded a Nobel Prize, Singer independently discovered this parasite. He read several communications on these subjects at the International Congress of Medicine which was held in London in 1913, and that year saw the zenith of his writing on these subjects. Two years before that he had published his first historical paper, and from 1914 onwards he devoted himself to historical subjects. A short period at Oxford and some years in the R.A.M.C. during the First World War were followed by a post at University College, London, first as lecturer in, and later as professor of, the history of medicine. Though the years in London until his retirement in 1942 were full of great achievement, it is since that date that Prof. Singer has reaped his richest harvests. Besides several scholarly books which are of great importance in the history of medicine, he has contributed lavishly to a specialized branch of the history of the chemical industry, and for six years he has laboured on the monumental "History of Technology", of which he was the sole begetter, and in the production of which he has shouldered the major burden. May the approaching publication of the second volume of that five-volume work stimulate him to continue making the world his debtor.

Biochemistry in Birmingham: Prof. R. H. Hopkins

PROF. R. H. HOPKINS retired from the Adrian Brown chair of malting and brewing and applied biochemistry in the University of Birmingham on September 30. A graduate of that University, he has been closely associated with the Department for many years. Thus, he was lecturer under Prof. Adrian Brown and retained that position for several years before accepting a post at the Heriot-Watt College, Edinburgh. In 1931 he returned to Birmingham, this time as head of the Department, a position he was to occupy for twenty-five years. The retirement of Prof. Hopkins may be said to close the second epoch in the history of what was originally the British School of Malting and Brewing. In the first period, 1900–20, the School was primarily concerned with these subjects; but already a wider field was being cultivated. In the earlier days of the second epoch a new pattern was being laid down, and in the research laboratories interest centred chiefly on the biochemistry of plant products, especially polysaccharides. A new building was occupied in 1927, and when Hopkins arrived in 1931 the time was ripe for further expansion. The original *raison d'être* of the Department was never lost sight of, and with the advent of a group of workers from the Institute of Brewing, fundamental work on biochemical aspects of brewing and on yeast nutrition was actively pursued. The emphasis in the Department was changing—from static to dynamic biochemistry—never more so than in the special field of the amylases which has always claimed so much of Hopkins's time and interest. During and after the Second World War, nutritional investigations led to interest in yet another field—the vitamins of the B group, with special reference to their role in germination, malting and brewing processes, and their assay by microbiological means. An increasing preoccupation with microbiological chemistry has been observable in recent years and has resulted in useful studies in the nutrition of yeasts and bacteria. Prof. Hopkins may look back with some satisfaction on the achievements of a small department, limited in resources and with no possibility of team-work in the modern sense. Should the rumoured expansion of biochemistry in Birmingham be achieved, the Department may look forward with confidence to yet a third epoch.

Imperial College of Science and Technology, London

The Imperial College of Science and Technology has now completed the first stage of the massive expansion being undertaken at the request of the Government. The plan, announced in 1953, is to double the size of the College to accommodate three thousand students of science and engineering. There are now 2,240 students at the College, 36 per cent more than in 1953. The number of teaching staff now stands at three hundred—a rise of 33 per cent. Twenty-seven new posts as professor or reader in the University of London have been established at the College and have been filled. They cover a wide range of subjects, from aeronautical structures, applied geophysics, instrument technology, parasitology and soil mechanics to nuclear power. A new building for aeronautics and chemical engineering is already partly in use, and will be in full operation in two months time. By this, by a reconstruction of the Students' Union and by a number of other building projects, the College has already added 20 per cent to its gross floor space. Work has now been started on the preparation of sites for large new buildings for engineering and physics.

University of Leeds

The following have been appointed to lectureships in the University of Leeds: N. Brook (colliery engineering), Dr. A. J. Manuel (physics), J. McFarlane (mining and mine surveying), A. Peck (mine surveying), and Dr. J. E. Saxton (organic chemistry). The title of visiting professor in the University has been conferred upon Prof. Darrell Pratt, of the University of Florida, who will be working with Prof. F. C. Happold in the Department of Biochemistry during the session 1956–57. The following gifts, among others, have been received by the University: £2,000 over two years to the Department of Inorganic and Structural Chemistry from Imperial Chemical Industries, Ltd., for work on vanadium pentoxide systems; £500 a year for three years to the Department of Physical Chemistry from the Distillers Company, Ltd., for the support of research; £1,000 to the Department of Civil Engineering from the Steelwork Society for research into stress distribution of high-tensile bolted structural connexions; £3,000 for 1955–56 to the Department of Mining from the National Coal Board (North-Eastern Division); £2,000 for 1955–56 to the Department of Coal Gas and Fuel Industries from the Gas Plant Manufacturers' Development Council; £1,350 to the Department of Textile Industries from Courtaulds, Ltd.; £9,000 over three years to the Departments of Medical Physics and Radiology and Radiotherapy from the Nuffield Foundation, for research on the intensification of X-ray fluorescent screen images.

The total number of full-time students registered at the University of Leeds is now 3,731, which is some 260 more than at the corresponding date last session; of this increase, at least two hundred are in the Faculties of Science and Technology. The new admissions are about 180 more than at the corresponding date last session; 60–70 of these are on the arts side and about 120 in science and technology.

Royal Society of Edinburgh: Officers for 1956–57

The following have been appointed to the Council of the Royal Society of Edinburgh for the session 1956–57: *President*, Prof. James Ritchie; *Vice-Presidents*, Prof. J. Norman Davidson, Principal H. B. Nisbet, Prof. Meirion Thomas, Prof. A. C. Aitken, Dr. J. E. Richey, Prof. D. Whitteridge; *General Secretary*, Prof. Norman Feather; *Secretaries to Ordinary Meetings*, Dr. T. R. Bolam and Dr. A. W. Greenwood; *Treasurer*, Mr. A. W. Young; *Curator of Library and Museum*, Dr. Douglas Guthrie; *Councillors*, Prof. E. L. Hirst, Dr. D. E. Rutherford, Dr. D. A. Allan, Prof. G. H. Bell, Dr. D. N. McArthur, Dr. A. G. MacGregor, Prof. C. H. Waddington, Dr. J. A. Macdonald, Dr. J. R. Peddie, Dr. R. Schlapp, Dr. J. B. Tait and Prof. G. M. Wyburn.

Metallurgical Reviews: a New Quarterly Journal

To all those concerned with any aspect of metallurgy, the appearance of a new quarterly periodical, *Metallurgical Reviews* (members of the Institute of Metals, 32*s*. 6*d*. or 5 dollars per year; non-members, 42*s*. or 6.50 dollars), will be of more than usual interest. Although published by the Institute of Metals, the interests of which lie in the field of non-ferrous metallurgy, the new publication will cover the whole field with the exception of mining, the extraction of metals from their ores, and practice in iron and steel works. It is intended that these reviews should be of a comprehensive and critical nature, and relate both to the industrial and the theoretical aspects of the subject. The four reviews contained in the first issue (pp. 156) fully satisfy these conditions. Prof. J.-J. Trillat (Sorbonne, Paris) has written on the metallurgical aspects of microradiography; Prof. C. R. Soderberg (Massachusetts Institute of Technology) on mechanical properties in relation to design requirements; D. M. Lewis (Aluminium Laboratories, Ltd.) on the principles of continuous casting of metals; and B. E. Hopkins (National Physical Laboratory, Teddington) on the preparation and properties of high-purity iron. All these are valuable compilations, very well prepared and illustrated, and on the average some sixty references are given to each section of the work. The Council of the Institute of Metals is to be congratulated on performing a most valuable service to those concerned with both the technology and the theory of metallurgy.

Two New Scottish Nature Reserves

The Scottish Committee of the Nature Conservancy has recently established new nature reserves at Inchnadamph, Sutherland, and Glen Diomhan, Bute. The former consists of 3,200 acres south-east of Loch Assynt and is a typical sample of west Sutherland countryside, ranging in altitude from about 230 ft. near Inchnadamph to 1,680 ft. on the summit of Beinn nan Cnaimhseag. Loch Mhaolachcoire is included within its boundaries. The reserve lies in a tract of great geological and physiographical interest, being at the western front of an area of disturbed Durness limestone of Cambrian age. At Beinn nan Cnaimhseag is an isolated outcrop of Torridon sandstone resting upon the Durness limestone. Although some of the limestone in the reserve is covered with acid drift and peat, much of it is exposed, and about four hundred acres consists of limestone pavements and scraps. The ground is partially covered by low willow scrub consisting mainly of *Salix myrsinites*, but also includes *S. repens*, *S. aurita* and hybrids. Mountain avens (*Dryas octopetala*) is abundant on the drier limestones, and there is a rich woodland flora of northern character including globe flower (*Trollius europaeus*) in some parts. The gorge of the Traligill Burn is well known to botanists. The karst type of limestone country with sink-holes, underground streams and limestone caves is also to be found, and the famous Allt nan Uamh bone caves contain Palæolithic cave earths with a fauna of Pleistocene mammals and traces of occupation by early man. The reserve has been established under an agreement with the owner, Mr. R. A. Vestey. The Glen Diomhan nature reserve consists of 24 acres of a steep-sided, post-glacial gorge in north-west Arran, lying between Meall nan Damh (1,870 ft.) on the west and Ben Bhiorach (1,572 ft.) on the east. The area is noteworthy for the occurrence in it of two rare whitebeams (*Sorbus arranensis* and *S. pseudofennica*), both of which are confined to Arran. They grow intermixed with rowan (*S. aucuparia*). The trees are mostly confined to a short length of the glen between the 300-ft. and 600-ft. contours and are found on both banks of the stream. The reserve has been established under an agreement with the Dowager Duchess of Montrose.

Three-dimensional and Two-phase Illustrations

THE firm of Industrial Photographs, Ltd. (34 Belwell Lane, Four Oaks, Sutton Coldfield), has produced some interesting three-dimensional pictures, called 'Vectographs', in which the solid effect is produced by means of an ingenious application of polarized light. The two component images necessary for a stereoscopic picture are printed in superposition on either side of a transparent support. The nature of this support and the printing solution used results in the production of two images in which the original photographic densities are reproduced in varying degrees of optical polarization. The light passed by the first image is polarized at right-angles to that passed by the second. This composite picture is viewed through a small binocular analyser, the lenses of which are two pieces of polarizing material with their directions of polarization at right angles to one another; these lenses act as filters and are so arranged that the left and right images are visible only to the appropriate eye, thus producing a clear and striking three-dimensional effect. Three examples of subjects illustrated are the chemical structure of graphite, a shadowed carbon replica of pearlite, and a cone of *Chamaecyparis lawsonia*. By another application of the process, two different aspects of a subject are similarly superimposed. Each is visible by polarized light in one plane only, and a piece of polarizing filter (or one lens of the binocular viewer) is rotated to show either image or both, or the transition from one to the other. An example of this type of two-phase picture is one in which the two aspects are the human skull and its associated muscles and tissues. The pictures are 4¼ in. × 5¼ in. in size and are designed for educational purposes. As an alternative to passing them around the lecture-room, they can be used as slides (though they are rather large ones) and projected on to a metallized screen. Each member of the audience must, of course, have a polarizing viewer.

Antarctica Exhibition at the British Museum (Natural History)

A SPECIAL exhibition on Antarctica has been arranged in the Mineral Gallery of the British Museum (Natural History) to mark the International Geophysical Year, 1957–58 and the Trans-Antarctic Expedition. The rock specimens of the Department of Mineralogy, which form the National Collection, include many from Antarctica. Three areas have been selected for exhibition. The first area is South Victoria Land, scene of many British expeditions, culminating in those of Shackleton and Scott. South Victoria Land is now a base for New Zealand and American parties, and the final destination of the Trans-Antarctic Expedition. The second area represented is Queen Maud Land, in the Norwegian section of Antarctica. Part of this territory was explored by the Norwegian–British–Swedish Expedition, 1949–52. The third area, part of the Falkland Islands Dependencies, including Graham Land and its offshore islands, is now being surveyed by many British parties. Four historical specimens displayed are: the gizzard stones of an emperor penguin taken on sea ice by Sir James Clark Ross's Expedition (H.M.S. *Terror* and H.M.S. *Erebus*) in 1849, which included rocks of continental character, and gave the first scientific evidence for the existence of a southern continent; a boulder of gneiss, a typical continental rock, dredged from the floor of the Southern Ocean by H.M.S. *Challenger* in 1874, which provided further evidence of a southern continent; rocks collected by Captain Scott's party on their return march from the South Pole in January 1912; and the Adélie Land stony meteorite, which is the only meteorite so far recovered in Antarctica. There are also photographs, paintings and maps illustrating antarctic conditions.

Michael Faraday and Spiritualism

IN 1853, Michael Faraday conducted an investigation of certain spiritualistic phenomena then causing considerable stir. Using a few simple pieces of apparatus of his own design, he succeeded in establishing the same kinds of controls that characterized his more famous experimental researches and provided a rational explanation for the observed set of phenomena that was satisfactory to all. No new and strange forces were uncovered. Instead, Faraday demonstrated conclusively that the performers produced the observed effects by ordinary physical means. What was noteworthy in this inquiry—and the reason Faraday's explanation proved to be satisfactory to both sides—was that he discovered that the performers were deceiving not just others, but themselves as well. Although the performers produced the observed effects, they did so unconsciously.

Faraday investigated two sets of phenomena, the levitation of tables and the turning of tables. In his "Observations on Mental Education", which was delivered as a lecture in 1854, he described the phenomenon of levitation. Of his investigation of the second kind of phenomena, Faraday prepared a report which was published on July 2, 1953, in the *Athenæum*, a journal devoted to English and foreign literature, science, and the fine arts, which was founded in 1828 and which continues to-day, after several mergers, as the *New Statesman and Nation.* A copy of this interesting report and some comments upon it have been set out in *Scientific Monthly* (83, No. 3; September 1956).

National Science Foundation Fellowships

The National Science Foundation, Washington, D.C., is offering three types of fellowship awards for advanced study and research in the natural sciences during the academic year 1957–58: predoctoral fellowships for college seniors and graduates (1,600–1,800 dollars); postdoctoral fellowships for those who have already gained a doctor's degree in science (3,800 dollars); and senior postdoctoral fellowships for those who have had a doctorate for a minimum of five years and have demonstrated unusual ability for research (4,000–10,000 dollars). The awards are open to American citizens and are tenable in any non-profit institution of higher education in the United States or abroad. The fields of study may be the mathematical, physical, medical, biological, engineering and other sciences, including anthropology, psychology (other than clinical), geography, certain inter-disciplinary fields, and areas of convergence between the natural and social sciences. About a thousand awards will be made and will be announced next March. Applications for predoctoral fellowships should be made by January 7, and for postdoctoral fellowships by December 24, to the Fellowship Office, National Academy of Sciences—National Research Council, 2101 Constitution Avenue, N.W., Washington 25, D.C. For senior postdoctoral fellowships application should be made by January 14 to the Division of Scientific Personnel and Education, National Science Foundation, Washington 25, D.C.

Conference on the Biology of the Hair Follicle and the Growth of Hair

An international conference on "The Biology of the Hair Follicle and the Growth of Hair" will be held under the auspices of the British Society for Research on Ageing at the Royal Society of Medicine during August 7–9, 1957. The Congress will deal with the gross and microscopic anatomy and histochemistry of the hair follicle and the hair, studies on mitoses of the hair follicle and effects of nutrition and hormones on hair growth, vascularity and patterns of growth, production of pigment, regeneration and *de novo* formation of hair follicles. Admission is by ticket, obtainable free of charge from the Honorary Secretary, British Society for Research on Ageing, Dr. G. H. Bourne, London Hospital Medical College, Whitechapel, London, E.1.

Announcements

Dr. J. R. Price, senior principal research officer in the Organic Chemistry Section of the Commonwealth Scientific and Industrial Research Organization, Australia, has been awarded the H. G. Smith Memorial Medal for 1956 of the Royal Australian Chemical Institute. The Medal is for contributions over the past ten years to the development of chemical science in the field of organic chemistry and biochemistry, and the award to Dr. Price is for his researches on several types of compounds, and especially on the alkaloids.

The Meldola Medal, which is the gift of the Society of Maccabæans, is being offered for award early in 1957 to the chemist who, being a British subject and less than thirty years old on December 31, shows the most promise, as indicated by published chemical work brought to the notice of the Council of the Royal Institute of Chemistry before December 31. Communications should be addressed to the President, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1, the envelope being marked "Meldola Medal".

Sir George Beilby Memorial awards, which are considered at intervals by administrators representing the Royal Institute of Chemistry, the Society of Chemical Industry and the Institute of Metals, are made to British scientific research workers, preference being given to investigations relating to the special interests of Sir George Beilby, including fuel economy, chemical engineering and metallurgy. In general, the awards are given to younger workers for original investigations over a number of years. For awards early in 1957, the attention of the administrators should be directed, before December 31, to work of the nature indicated, all communications being addressed to the Convenor of the Administrators, Sir George Beilby Memorial Fund, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1.

Dr. R. Cockburn deputy controller of electronics, Ministry of Supply, has been appointed controller of guided weapons and electronics in the Ministry.

Mr. C. E. Lambert, representing the Colonial Territories, has been elected chairman of the Executive Council of the Commonwealth Agricultural Bureaux, in succession to Mr. J. E. C. Coventry, who represented the Federation of Rhodesia and Nyasaland. Lieut.-Colonel V. A. Nicholas, representing Ceylon, has succeeded Mr. Lambert as vice-chairman.

Prof. F. G. Gregory, of the Research Institute of Plant Physiology, Imperial College of Science and Technology, London, will deliver the Amos Memorial Lecture at the East Malling Research Station, Kent, on November 15. He will speak on "The Place of Plant Physiology in Fruit-growing".

Prof. R. B. Woodward, professor of chemistry, Harvard University, will deliver the eighth annual Ciba Foundation Lecture on December 5 at 5 p.m. in the meeting room of the Zoological Society of London; his subject will be "Recent Advances in the Chemistry of Natural Products". Admission is by ticket only, obtainable from the Assistant Secretary, The Ciba Foundation, 41 Portland Place, London, W.1

A one-day conference on "Automation, Education and Training" is being organized by the British Association for Commercial and Industrial Education, and will be held in the Royal Festival Hall, London, on December 4. Particulars can be obtained from the Association, at Management House, 8 Hill Street, London, W.1.

Erratum. In the communication entitled "Antagonists of the Action of Reserpine on Smooth Muscle" in *Nature* of October 20, p. 859, col. 2, par. 2, line 3, for "serotonin (15–40 mgm. per ml.)" read "serotonin (15–40 nanograms per ml.)".

THE DIRECTION OF RESEARCH ESTABLISHMENTS

THE scale, complexity and cost of scientific research are mounting rapidly. Laboratories are growing not only in number but also in size. To meet these ever-growing needs without waste of money or that vastly more precious commodity, scientific brain-power, a high order of organization and management is required. This is a comparatively new problem of administration—research has developed into a large-scale industry only in the past few decades—and there are almost no precedents in any field of human endeavour for showing the large-scale organization of mental and imaginative creativeness as a team effort.

The direction of research establishments was the subject of an international symposium organized by, and held at, the National Physical Laboratory during September 26–28. Delegates from seventeen countries attended. They were mainly directors of large laboratories—government, industry and public corporations—with a small representation of universities. Attendance was severely limited to 150. Papers were circulated before the conference, so that most of the conference time could be devoted to discussion.

The general plan of the symposium was that the first day should be devoted to choice of project, general problems of organization and control of research, and the personal and social factors affecting creativity in scientists. The second day provided three parallel sessions on general organization, staff and communication. The third day started with reports from, and joint discussion on, the previous day's sessions, followed by consideration of the assessment of the work of a research laboratory and a general summing up.

The proceedings were opened by Dr. G. B. B. M. Sutherland, who had just previously taken up his appointment as director of the National Physical Laboratory. The first session was then devoted to the strategy of research and the choice and termination of research projects. Prof. J. D. Bernal introduced a thought-provoking paper on "Fundamental and Applied Aspects of Research Problems". In this he emphasized that finding the problem is much more difficult than finding the solution. It is not the problem but the particular need or difficulty that stands out. It is necessary, therefore, before research is started, to reduce the immediately perceivable gap between what is known and what is required to something which can be measured scientifically. He described the working of various types of research laboratories and suggested that one of the most important aspects of the integration of research is that subsidiary problems should be referred to appropriate organizations such as research associations or national laboratories.

In dealing with invention, Prof. Bernal pointed out that its history shows that actual success depends not only on originality and imagination but also on knowing what to invent, that is, on a knowledge of requirements and of market possibilities and costs and prices. The frequent practice of firms in not allowing employees to profit directly from their invention was described as being the 'best way of killing the goose that lays the golden egg'. Prof. Bernal also thought that scientists tend to work too long on lines of traditional, set problems, whereas major advances have occurred when this rule is broken. He advocated a closer liaison between industrial and university research workers as providing two-way benefits.

The other paper in this session was by Dr. Willis Jackson, on "The Research Project—Its Choice and Termination". In this, comparisons and contrasts were drawn between the factors governing the initiation and termination of research in universities and in industry, although the outlook, approach and method of the true research worker were stated to be the same whatever his setting.

Dr. Willis Jackson gave various examples of work originating in individual inspiration which had extensive technological consequences not originally envisaged. He pointed out that the industrial research laboratory is fortunate in having ready access to the wider environment of a range of design and manufacturing activities as an outlet for its personnel. For this and other reasons he regarded it as essential for all industrial research recruits to spend a training period in carefully chosen departments of the main factory.

The first part of the second session was devoted to consideration of creativity. "Creativity and the Scientist" was introduced by Prof. Morris Stein, of the University of Chicago, and "Personality and Social Factors related to Creativity", by Prof. D. J. van Lennep, of the State University, Utrecht.

Prof. Stein surveyed the work of his team on the sociological and psychological factors related to creativity in industrial research chemists. The object of this work is the understanding of the processes involved in creativity so as to facilitate the selection of creative scientists and the administration of creative research. He stated that creativity is a process of hypothesis formation, hypothesis testing and communication of results, and that scientists can be creative in either or all of these fields. He stressed that there are differences between scientists working in different fields and in different environments, and advised employers to have a clear picture of the kind of man they want before starting to look for creativity.

Prof. van Lennep made a preliminary division of research workers under three categories: need for achievement, problem-solving ability and creativity; and he pointed out that a large research laboratory must have staff of each type. For physicists and chemists he postulated that creative workers are less dependent with respect to their environment; are less rigid and dogmatic and have a characteristic time perspective.

The final paper in this session was given by Mr. D. R. Willson, technical secretary of the Atomic Energy Research Establishment, Harwell, on "Budge s and Administrative Controls". He discussed the needs for budgets and controls in research and development establishments, and how those which are essential can best be applied.

The general organization session started with discussions of a paper by Mr. E. S. Hiscocks, secretary of the National Physical Laboratory, on "Some

'Factors affecting Laboratory Administration". In this paper Mr. Hiscocks dealt first with the changed requirements caused by the transition of research from a craft to a large-scale industry. The effects of size on the organization were then examined and the great need for devolution stressed. The division of work in large laboratories was next considered, as were also the effects on their staffing and organization of large-scale, expensive equipment.

The next paper, on "Science and the Workshop", by Dr. R. Vieweg, president of the Physikalisch-Technische Bundesanstalt, was presented by Dr. A. Scheibe, his vice-president. This discussed the place of workshops in laboratories and the types of shops and their organization to meet the requirements of modern research. This raised the controversial question of the degree of centralization of services required to produce optimum results.

The afternoon of this group session was devoted to laboratory buildings. Dr. F. M. Lea, director of the Building Research Station (Department of Scientific and Industrial Research), outlined the requirements and Mr. H. A. Snow, superintending architect, Ministry of Works, gave the architect's answer to these demands.

Punch remarked, more than twenty years ago, that the greatest of all the research problems is the people who do the research, and this was shown to be still the case by the discussions of the staff group. Dr. W. S. Bristowe, head of the Central Staff Department, Imperial Chemical Industries, Ltd., and Dr. F. T. Rosser, director of administration, National Research Council of Canada, presented papers on selection and personal assessment of staff. Dr. Rosser's account of what he described as "fantastic" methods used by employers in Canada to obtain scientists caused considerable comment in the daily press. Prof. H. A. Shepard, of the Massachusetts Institute of Technology, next discussed "Superiors and Subordinates in Research", and described the new orientations that have emerged from the work of sociologists in this field over the past twenty-five years. Prof. Shepard has himself made a significant contribution to these studies. Sir Charles Harington, director of the National Institute for Medical Research, then introduced the subject of "Staff Groupings and the Flow of Authority". The last subject discussed in this session was "Incentives". This was introduced by Mr. Stanley Mayne, secretary of the Institution of Professional Civil Servants. It was a refreshing experience for the 'managers' to hear the views of the 'managed' on this very important subject.

The third group session—that on communications—dealt first with internal communications in a large research laboratory and was introduced by Dr. C. G. Williams, director and general manager of 'Shell' Research, Ltd. This was followed by a paper "Studies in the Use of Technical Information in the Smaller Industrial Establishments", by Mr. Louis Moss and Mr. L. T. Wilkins, of the Central Office of Information. This paper described a statistical survey recently made into the dissemination of technical information in industry; and preliminary results of an investigation of the electrical and electronics industry in Great Britain were presented for discussion by Mr. Geoffrey Thomas in the unavoidable absence of Mr. Moss.

Dr. A. T. Green, director of the British Ceramic Research Association, presented a paper by himself and Dr. A. E. Dodd, information officer of the Association, on "Knowledge: Passing it on—Getting it used", and Mr. A. J. Garratt, liaison officer of the National Physical Laboratory, dealt with problems of "Extramural Communications".

Mr. M. W. Thistle, chief of the Public Relations Branch, National Research Council of Canada, presented, in his inimitable style, the last paper in this group, on "Some Fundamental Difficulties in Popularizing Science". He contended that although only perhaps 0·01 per cent of information of a highly sophisticated nature can in fact be communicated to an unsophisticated audience, the amount of information emanating from science is such that the quantity ultimately absorbed is still significant.

Dr. D. W. Hill, director of the Shirley Institute, Didsbury, was chairman of the session on general organization, Dr. J. Bronowski, director of the Coal Research Establishment of the National Coal Board, was chairman of that on staff and Dr. A. King, Department of Scientific and Industrial Research, of that on communication. These chairmen presented to the complete conference next morning admirably lucid and stimulating summaries of the previous day's discussions.

The final session considered a paper on the assessment of the work of a research laboratory by Mr. A. H. Wilson, managing director of research and development, Courtaulds Ltd., and chairman of the Industrial Research Committee, Federation of British Industries. Mr. Wilson pointed out that the standing of an academic laboratory depends largely upon subjective judgments—the æsthetic appeal of its results to the general body of academic scientists—whereas in the industrial world a laboratory is of no importance unless it exerts a positive influence on its industry, and this, ideally, is capable of measurement. On the subject of stopping research, Mr. Wilson advocated the early and continuous assessment of the whole project and its consequences—a process in which the research worker must take part and the consequences of which he should, therefore, accept. Discussion on this paper and on the conference in general was opened by Dr. A. V. Astin, director of the National Bureau of Standards, Washington.

A summing up of the conference was then given by Dr. H. W. Melville, secretary of the Department of Scientific and Industrial Research, who was chairman of this session.

It is impossible in an article of this length to summarize the many points of view put forward; but it became evident that many of the major problems of large-scale research are fundamentally the same whatever the country and whether the research is on behalf of government or industry. It was also surprising that the solutions evolved by apparently widely differing organizations bear close resemblances. This applies particularly to general organization of research services, and to the broad problems of the selection and personal assessment of staff. However, one of the major difficulties of the government research institution—what to do with the research scientist who has become less productive—is not shared to anything like the same extent by industry, where young men from the research department are continually transferred to other branches of the industry, such as technical sales, production, control, etc. The problems of internal communication are broadly similar whatever the type of industry and naturally increase with the size of the institution; but here again industry is not faced with many of the problems of external communication that are major concerns of government research for the civilian economy.

Although most of the participants in the symposium and many of the contributions came from those actually engaged in directing or administering large research establishments, considerable interest was shown in the 'research into research' papers, such as those from the psychologists, sociologists, statisticians and the trade union side. It is now clear to many research directors that, to borrow a phrase from Dr. Ellis Johnson, we should have more "operations research looking at research operations".

A surprise to the organizers of this symposium was the large number of people from many parts of the world who wished to attend, and it has become clear that discussion of problems such as those dealt with, and of the many more which time did not permit to be raised, must continue. The form which this follow-up and possible extension should take is now under consideration.

All papers presented at the symposium and summaries of the discussions will be published as soon as possible by H.M. Stationery Office, London.

E. S. HISCOCKS

INTERNATIONAL SOCIETY OF BIOCLIMATOLOGY AND BIOMETEOROLOGY

THE first business and scientific meeting of the International Society of Bioclimatology and Biometeorology was held at Unesco House, Paris, during August 29–31. Approximately sixty members, representing sixteen nations, were present. The major items covered included the drawing up of a set of statutes; the election of an executive board and a governing council; the introduction to members, through a series of area reports, of the various aspects of bioclimatological research in progress in different parts of the world; and the presentation of a small number of scientific papers.

Bioclimatology is not a new science, nor is it yet a unified one. The scope of the subject was brought out at the Paris meeting, and it speaks well of the new Society that its prime purpose should be to "unite . . . all Bioclimatologists working in the fields of Medical, General Botanical, Agricultural, Forest, General Zoological, Veterinarian, Entomological and Cosmic Bioclimatology and other future branches of Bioclimatology, . . . to facilitate the development of Bioclimatology". To achieve these ends it proposes to organize symposia, create a clearing house for publications, inaugurate a journal, institute sub-committees in specialized fields and, so far as possible, obtain funds for the fostering of research. The administration of the society is under the ægis of an executive board of seven members, assisted by a governing council of twenty-five. The following were elected to the executive board: *President*, Dr. F. Sargent (United States); *Vice-Presidents*, Prof. H. Berg (Germany), Dr. H. Boyko (Israel) and Prof. L. Emberger (France); *Secretary-Treasurer*, Dr. S. W. Tromp (Netherlands); and *Advisory Members*, Mr. W. E. Arnould-Taylor (Great Britain) and Dr. W. G. Wellington (Canada).

A total of seven area reports briefly described the work of individual bioclimatologists in North America, Western Europe, Africa, South-East Asia and Israel. Such a review provided an excellent, up-to-date account of research in progress. In addition, the width and variety of interests within the subject were made apparent through these reports, as can be seen from the inclusion of such topics as: asthma and hay-fever studies in relation to pollen, fungi and meteorological conditions of the atmosphere; the influence of climate on the behaviour and survival of forest insects; the use of weather data in connexion with irrigation; and a study of problems of clothing and resistance to extreme climates arising from pilgrimages by sea and land to Mecca.

Four sub-committees were instituted, the function of which is to collate and disseminate information on the respective specialized fields of ionic research in bioclimatology, allergy, ecological climatology and bioclimatological instruments. A proposed fifth sub-committee on nautical bioclimatology was referred to the executive board for further consideration.

It was proposed to hold a second meeting of the Society in Vienna in 1957, although a subsequent annual periodicity is not necessarily to be inferred. However, the Paris meeting showed many potential attenders to have been pre-occupied with earlier commitments, and lacunæ in some area reports suggest that scientists in certain areas and disciplines may not have fully realized the extensive nature of the Society's intentions. For these reasons and others, an early re-assembly appeared desirable.

The Society largely owes its inception to the initiative of Dr. S. W. Tromp, who got into touch with bioclimatologists in different parts of the world during the previous twelve months and also played a major part in the organization of the Paris meeting. His acceptance of the secretaryship, which he will conduct from 54 Hofbrouckerlaan Oegstgeest, Leyden, is a fortunate event for the Society.

M. J. DELANY
F. L. WATERHOUSE

YEAST IN INDUSTRY

UNDER the joint sponsorship of the Dublin and District Section, the Microbiology Group and the Food Group of the Society of Chemical Industry, a symposium on "Recent Studies in Yeast and their Significance in Industry" was held in Dublin during September 17–19. The sessions were held in the Rupert Guinness Hall by kind invitation of Arthur Guinness Son and Co. (Dublin), Ltd., on behalf of whom Sir Richard Levinge welcomed the 125 members of the symposium; some seventy-five members attended from overseas. The basis of the symposium was provided by thirteen papers, the reading of which was followed by lively discussions in which many members participated. The chair was occupied in succession by Mr. H. J. Bunker, Prof. T. Dillon, Dr. A. K. Mills, Dr. A. J. Amos and Dr. L. A. Allen.

The first paper, by Dr. A. A. Eddy (Brewing Industry Research Foundation), dealt with "Some Chemical Aspects of Yeast Growth". First, Dr. Eddy described the use of media containing L-lysine as sole major source of nitrogen for the isolation of wild yeasts and the estimation of the extent to which they contaminate brewery pitching yeasts. He then discussed three commercially important aspects of the behaviour of yeasts, namely, head retention, flocculence and finability, which are associated with the surface structure of yeast. In particular, he indicated how these aspects may vary from strain to strain and suggested the division of yeasts with respect to flocculence into those which (*a*) flocculate under the influence of chemical factors (sugars, *p*H, ethanol); (*b*) undergo mutual flocculation; and (*c*) are non-flocculent.

Presenting a paper on "Inositol Deficiency in Yeast with Particular Reference to Fat Production" on behalf of S. W. Challinor, N. W. R. Daniels and J. C. Hall (University of Birmingham), Dr. Challinor reported that the fat content of the cells of a brewer's yeast is greatly increased by growth in a medium deficient in inositol. The possible commercial value of this phenomenon is enhanced by the fact that such fatty, inositol-deficient cells are also more fragile than are normal cells, so that extraction of fat is facilitated.

In his paper on "Amylase Systems in Brewery Yeasts", Prof. R. H. Hopkins (University of Birmingham) pointed out that, although glucose, maltose and maltotriose are the only sugars of the starch series fermentable by them, brewer's yeasts elaborate (*a*) a debranching enzyme ('isoamylase') which splits α-1.6-linkages in branched structures such as amylopectin and its β-limit dextrin, and (*b*) a branching enzyme which transforms the straight-chained amylose into a branched compound. Yeasts which ferment starch and dextrin may occur as contaminants in the brewery. Such is *Saccharomyces diastaticus*, which secretes glucamylase (amyloglucosidase) at or near the cell surface. This enzyme splits successive terminal glucose residues from α-1.4-linked polyglucosans to yield β-glucose. Infection by *Sacch. diastaticus* may therefore cause 'super-attenuation' in bottled beers. In other circumstances, *Sacch. diastaticus* is potentially useful for producing ethanol from starchy materials and for carrying further the attenuation of beers.

Mr. F. W. Beech (Long Ashton Research Station) spoke on "Yeast Control in Cider Fermentation". The inoculum which initiates the fermentation of apple juice is provided by the natural microflora of the fruit. After outlining the changes in the yeast populations of fermenting ciders, Mr. Beech discussed some methods of microbiological control. Thus, a French method consists in reducing the nitrogen content of the juice. In England, aerobic spoilage organisms may be suppressed by keeping fermenting and stored ciders under anaerobic conditions, the yeast population being controlled simultaneously by mechanical methods. Sulphur dioxide, added to the original juices, effectively controls both yeasts and bacteria.

Two prominent Continental scientists provided papers to illuminate those little-understood, but fundamental, aspects of yeast behaviour which centre around the phenomenon known as the 'Pasteur effect'. Dr. H. Holzer (University of Hamburg), in his contribution, "Regulation of Carbohydrate Metabolism in Yeast Cells", adduced evidence for the theory that the key enzyme system affected by the change from anaerobic to aerobic conditions is that catalysed by triosephosphate dehydrogenase, the action of which depends on the available adenosine diphosphate and orthophosphate. Thus, there is a decrease in concentration of orthophosphate associated with the functioning of terminal respiratory processes brought into action when oxygen is introduced into a system fermenting under the action of living yeast. The resultant limitation of supply of orthophosphate will therefore restrict glycolysis. Ultimately, the Pasteur effect appears to be associated with a shift of adenosine triphosphate from the cytoplasm to the mitochondria. Dr. Holzer also discussed the occurrence of aerobic fermentation in connexion with growth. Aerobic fermentation increases when ammonium salts are added to yeast cells which are oxidizing glucose. In these circumstances, the increase in cell substance is largely due to the amination of α-ketoglutarate to glutamate catalysed by glutamic acid dehydrogenase in the presence of coenzyme I. This enzyme and the transaminase catalysing the formation of aspartate from glutamate and oxalacetate are present in yeast.

An obverse aspect of the Pasteur effect was presented by Dr. P. P. Slonimski (University of Paris) in his paper, "Respiration and Growth of Yeasts", in which he described studies involving respiratory mutants and the measurement of cell synthesis under anaerobic and aerobic conditions. *Growing* baker's yeast, even if aerated, ferments glucose: in the exponential phase, respiration is weak, the Pasteur effect is inoperative and ethanol accumulates. In this phase cytochrome synthesis is inhibited by glucose fermentation (the 'counter-Pasteur-effect'). Only in the last phase of growth, when "yeast dissimilates the alcoholic products of its own dissipation", is ethanol respired. Apart from his main thesis, Dr. Slonimski directed attention to a serious systematic error caused by absorption of carbon dioxide in work involving the measurement in conventional manometric apparatus of oxygen uptake when the ratio of carbon dioxide evolution to oxygen uptake is large, as is indeed the case with yeast. He also reported a requirement for ergosterol shown by yeast growing under strictly anaerobic conditions.

In passing, it would appear that some of the work described by Drs. Holzer and Slonimski supports the contention that the pathways of aerobic and anaerobic dissimilation in yeast are common at least up to the pyruvate stage.

Reading the paper by P. F. E. Mann, W. E. Trevelyan and J. S. Harrison (Distillers Co., Ltd.) on "Measurement of Levels of Metabolites within the Yeast Cell during Fermentation", Mr. Mann described the application of ion-exchange resins to the analysis of heat-killed yeast for intermediates and coenzymes. Such analyses promise to yield important information concerning the mechanism of regulation of the fermentation cycle. After a routine of elution has been established, separations are effected and fractions are analysed by simple techniques including measurements of ultra-violet absorption and estimations of total hexose, pentose, fructose and total phosphate. The quantitative results support the hypothesis that the enzymes which catalyse the reversible reactions of fermentation are in excess, so that, at the steady state of fermentation, their substrates are in equilibrium. Furthermore, in a simple medium, the saturation of carboxylase by its substrate, pyruvate, imposes on the rate of fermentation an absolute limitation which can be lifted by addition of thiamine. The high metabolic activity of trehalose and trehalose phosphate during the early stages of fermentation, as noted by these workers, is strong presumptive evidence that these substances play important parts in the metabolism of yeast.

Prof. E. J. Conway (University College, Dublin) contributed a paper on "Active Transport across the Yeast Cell Membrane", a subject with which his name is inseparably connected. He described how the material requirements of yeast enter the cell largely as a result of active transport during fermentation, a process requiring energy derived from other systems and effected by means of carriers, the general cationic carrier being a redox carrier of the cytochrome type. The affinity of the carrier for potassium ions is much greater than that for sodium or magnesium ions.

Aspects of yeast genetics were dealt with in two papers which followed the showing of the film, the "Life Cycle of the Yeast Cell", made for the Anheuser-Busch Co., with a commentary by C. C. Lindegren. Mr. R. B. Gilliland introduced the film and followed with a paper on "Yeast Genetics in Industry". He said that, as yet, the application of the technique of breeding yeasts for the purposes of brewing beer is disappointing, partly because of difficulties inherent in a yeast-breeding programme and partly because the assessment of desirable qualities is so difficult. The situation with respect to other yeast industries appears to be more hopeful, and the possibilities of polyploid yeasts have yet to be examined. On the more positive side, the study of yeast genetics has accumulated valuable data on the inheritance of the ability to flocculate and to ferment maltotriose, dextrin and starch. In more academic fields, the genetic analysis of yeast hybrids may find use in the separation of yeast enzymes.

In a paper on "Some Genetical Aspects of Panary Fermentation", Mr. R. R. Fowell (Distillers Co., Ltd.) presented the results of fermentometer tests on standard doughs fermented by yeasts obtained by breeding in a scheme which permitted subsequent genetical analysis. The results for the 1 hr. volume tests can be explained in terms of four major genes operating for dominance, but those for the 1–3 hr. test are complicated by action of genes operating negatively. He concluded that detailed genetical analysis of the haploid parents is necessary before the panary performance of individual hybrids could be predicted.

"The Utilization of Flour Sugars during Panary Fermentation" was discussed by Dr. R. R. McKenzie (Distillers Co., Ltd.). The subject had been studied by the application of quantitative paper chromatography to that fraction of flour extracted by aqueous ethanol. The observed changes in concentration of glucose, sucrose, glucodifructose and lævosine during fermentation were presented and their significance discussed.

The final paper, by Dr. J. White (Fardon's Vinegar Co., Ltd., Birmingham), on "Influence of Environmental Factors upon Yeast Behaviour", urged a greater appraisal of environmental effects as a step towards the production of yeasts of high fermentative capacity and good keeping qualities. The importance of such effects was illustrated by reference to the phenomenon of 'osmosensitivity', the conditions for which are developed by growth of yeasts in direct culture, but not by growth under conditions of incremental feeding. Dr. White also discussed the change in enzyme content of yeasts in relation to the capacity to ferment glucose and maltose and to secrete invertase. The enzyme content is often influenced both by the stage of harvesting of the yeast and by the nature of the sugar present in the medium.

The final summing up of the symposium was made for the brewing industry by Dr. A. H. Cook (Brewing Industry Research Foundation) and for the baking industry by Dr. J. B. M. Coppock (British Baking Industries Research Association). Dr. Cook pointed to the recent upsurge of yeast research, but also indicated the gulf which still separates pure research from the reality of technological practice. Dr. Coppock directed attention to the new questions posed as a result of every scientific advance. Both speakers brought out the value of work ostensibly carried out in one field to work in another field: in particular, the 'cross-linking' between brewing and baking had manifested itself in this symposium.

Perhaps it was surprising that no paper devoted to questions of the fundamental nutrition of yeast was presented. Such questions, of course, arose incidentally; but it is to be hoped that this deficiency does not reflect a neglected aspect of yeast research. For all that, the symposium was undoubtedly most successful: the amount and vigour of the discussion succeeding each paper testified to the interest aroused at this most informative and stimulating meeting. It is also necessary to add that splendid organization and generous hospitality, for the major part of which the symposium was deeply indebted to the firm and staff of Arthur Guinness, Son and Co. (Dublin), Ltd., contributed substantially to its success.

C. Rainbow

FREE RADICALS

SYMPOSIUM OF THE CHEMICAL INSTITUTE OF CANADA

A SYMPOSIUM on recent progress in the production, isolation and identification of free radicals was held during September 10–11 in the Chemistry Department of Laval University, Quebec. The meeting was sponsored by the Physical Chemistry Division of the Chemical Institute of Canada, and the arrangements were made by Dr. J. A. Morrison (National Research Council) and Prof. P. A. Giguère (Laval University).

The first group of papers dealt with spectroscopic studies of radicals produced by flash photolysis or shock waves. The paper by Drs. G. Herzberg and J. Shoosmith (National Research Council, Ottawa) discussed the CH_3 and CD_3 radicals. Although their spectra are predissociated, the structure of the CD_3 band at 2140 A. indicates that one state, probably the upper, is planar with $r_0(CD) = 1{\cdot}072$ A. and that the other state is slightly bent. Further work is in progress with the view of finding a predicted 'forbidden' transition in the visible which would not be predissociated.

Prof. G. Porter (University of Sheffield) presented a paper showing that simple aromatic radicals such as benzyl can be observed in vapour phase and in solution using flash photolysis, as well as in rigid media at low temperatures. He cited recent work by Bridge and Porter on the photochemistry of quinones in solution, where triplet states, semiquinone radicals and radical ions have been observed and their reactions studied.

Two papers from the National Research Council (Ottawa) dealt with triatomic radicals. In the first of these, Dr. D. A. Ramsay discussed the spectra of HCO, NH_2 and PH_2, all of which show long progressions of the bending vibration ν_2 due to a large difference in bond angle between the upper and lower states. The NH_2 radical has a $^2B_1$ ground state with $r(NH) = 1{\cdot}025$ A. and a bond angle of 103°. Its upper state is linear, probably $^2\pi_u$, and provides the first example of the interaction of the electronic angular momentum and the vibrational angular momentum of the bending mode of a linear molecule which was predicted by Renner. For PH_2 and PD_2 the bending vibrational interval in the upper state is found to pass through a minimum with increasing vibrational quantum number (v'_2). This is thought to be due to steric repulsion of the hydrogen (or deuterium) atoms at large vibrational amplitudes. The second of these papers was presented by Dr. F. W. Dalby, who showed that bands near 7500 A. tentatively assigned to DCO by Herzberg and Ramsay are due to DNO. Bands due to HNO in this region of the spectrum and lasting up to 1/10 sec. have been obtained in the flash photolysis of nitroethane, amyl nitrite and ammonia plus nitric oxide.

The only paper describing shock-wave techniques was given by Dr. N. Davidson (California Institute of Technology), who has studied the decomposition of nitrogen pentoxide in an excess of argon. In this system he was able to photograph the absorption spectrum of the NO_3 radical and to measure the rate constants of the following reactions:

$$N_2O_5 = NO_3 + NO_2$$
$$NO_3 + NO_3 = 2NO_2 + O_2$$
$$NO_2 + NO_3 = NO_2 + O_2 + NO$$

The discussion of these papers brought out both the relative advantages and limitations of these techniques and of work in rigid media, the conclusion being that they were complementary to each other.

The second group of papers dealt with the mass-spectrometric detection of free radicals and atoms produced in a variety of ways. Drs. W. A. Bryce, D. J. Fabian and K. U. Ingold (University of British Columbia) used the pyrolysis of mercury dimethyl to produce methyl radicals which reacted with oxygen in a quartz vessel designed to eliminate the need of a carrier gas. CH_3, CH_2, CH_3O_2, CH_3O, OH and HO_2 were among the radicals detected. In his paper, Dr. F. P. Lossing (National Research Council) described the detection of free radicals in the mercury photosensitized decomposition of acetaldehyde, acetone, ethylene, etc., using a flow system; by varying the length of the irradiated zone it was possible to distinguish between primary processes and secondary reactions. Dr. Lossing also showed that recent calculations of free-radical ionization potentials by Dr. J. A. Pople were in good agreement with the experimental values.

The electric discharge was the source favoured by Drs. S. N. Foner and R. L. Hudson (Johns Hopkins University) and by Drs. J. Herron and H. I. Schiff (McGill University, Montreal). The former have studied the formation of the HO_2 radical in a variety of systems and have found that an important homogeneous reaction is

$$OH + H_2O_2 = HO_2 + H_2O$$

The latter have studied the reaction of oxygen atoms with various species and find a rate constant of 3×10^{10} ml. mole^{-1} sec.$^{-1}$ for bimolecular reaction with nitric oxide.

The papers by Drs. P. LeGoff and L. P. Blanchard (University of Nancy) and Dr. A. J. B. Robertson (King's College, London) discussed processes occurring on hot metal surfaces in the presence of gases at low pressures. The former authors observed such species as CCl_2 from CCl_4 and CS from CS_2. Dr. Robertson discussed the adsorption of ethane and oxygen on platinum surfaces, and showed that the decomposition of the former was not in accordance with the transition-state theory. This point was further brought out in discussion, as was a general agreement over the mechanism of the formation and removal of the HO_2 radical which is still eluding the spectroscopists. Dr. C. K. Jen (Johns Hopkins University) reported unsuccessful searches over a wide range of the microwave region, and, in a later paper, Prof. P. A. Giguère and Dr. K. B. Harvey (Laval University) reported their failure to date to obtain the infra-red spectrum of HO_2 at low temperatures by condensing the products of a discharge through water vapour.

The next two papers described work at the National Bureau of Standards (Washington, D.C.) on the products from a microwave discharge through nitrogen collected on a surface at liquid-helium temperature. Dr. A. M. Bass discussed the experimental side of the work, the most striking feature of which is a green glow from the condensed solid with a half-life of about 15 sec. after the discharge has been switched off. Dr. C. M. Herzfeld showed that this spectrum arises from the $^2D \to {}^4S$ atomic transition of nitrogen, the position of which is shifted by the presence of molecules within one or two angstroms. Also present are bands attributed to a $^5\Sigma_g^+ \to A^3\Sigma_u$ transition of N_2, the $^5\Sigma$ state arising from normal atoms and having a very shallow minimum. Dr. G. C. Pimentel (University of California, Berkeley) described infra-red studies of radicals trapped during the photolysis of hydrazoic acid in an inert matrix at 30° K. There is strong evidence for NH_2 and N_3 radicals in this system. This produced a lively discussion, and Pimentel's work agrees with that of Dr. B. A. Thrush (Cambridge), who has found the ultra-violet absorption spectra of N_3, NH and NH_3 in flash photolysis of hydrazoic acid. N_3 was probably absent in the work at the Bureau of Standards, as its ultra-violet spectrum was not observed. It is surprising that N_3 is not formed from a metastable N atom and an N_2 molecule in this system; but Herzfeld has estimated the binding energy of the atom to be only a few hundred wave-numbers.

Dr. P. Smith (Purdue University, Indiana) presented evidence from various sources for the existence of the HO_3 radical and H_2O_4. No one present had any direct experimental evidence of these species.

The last three papers dealt with paramagnetic resonance. Dr. R. Livingston and H. Zeldes (Oak Ridge, Tennessee) pointed out the importance of using single crystals if trapped radicals were to be positively identified in irradiation experiments at low temperatures. They had, however, good evidence for OH radicals in the glass obtained by condensing the products of a discharge through water vapour. Drs. C. K. Jen, S. N. Foner, E. L. Cochran and V. A. Bowers (Johns Hopkins University) studied the products condensed from a discharge through hydrogen at liquid-helium temperatures. They found two triplets and a quartet near the free-electron resonance, and suggested that these might be due to H_3 or triplet H_2.

Dr. J. E. Wertz (University of Minnesota) discussed the hyperfine structure of the resonance spectra of semiquinone radicals; this is determined by the number and distinguishability of the protons present in the radical and greatly facilitates identification of the steps in quinone reactions. The discussion showed that this technique had great sensitivity and could well be applied to short-lived species.

The credit for the success of the meeting must be shared between the organizers and the authors of the nineteen papers presented, which dealt with very recent advances in fields that were, almost without exception, completely unknown ten years ago.

B. A. Thrush

INSPECTION OF INDUSTRIAL POLLUTION IN BRITAIN

REPORT FOR 1955

The ninety-second report on alkali, etc., works in England and Wales and in Scotland by the chief inspectors, covering 1955*, records 921 works in England and Wales registered under the Act at the end of the year, operating 1,794 processes, which is a decrease of six in the number of works and an increase of ten in the number of processes. The 3,894 visits and inspections made during the year included 165 special visits by the chief and deputy chief inspectors; of the total, 521 visits were to or in connexion with works not registered under the Act, and a further 60 visits were to or in connexion with colliery, spoil-banks. During the inspections, 2,057 quantitative analyses were made of gases evolved from processes in operation, and 827 special samples were submitted for detailed examination to the Government Chemist. Complaints and requests for technical advice and assistance involved a hundred registered and ninety-four non-registered works, the corresponding figures for 1954 being seventy and ninety, respectively; the increase is attributed not to deteriorated conditions but to a greater public awareness of the desirability of cleaner air. During the past few years there has been an increase in what are conveniently termed "area complaints", the complaint being directed against emissions from a highly industrial area or one of intensive production, such as Trafford Park, Manchester, and the Thames-side cement area, rather than against that from individual works.

On twenty-one occasions the total acidity of gases escaping to the atmosphere exceeded the statutory limits, and a further twenty-seven infractions related to failure to use "best practicable means". Since on formal notification of infraction suitable action ensued, there was no occasion to institute proceedings. Visits were paid both to the oil-fired Bankside and the coal-fired Battersea electricity generating stations, both of which are in London, to assess the efficiency of the installations for washing flue gas. While the position at Bankside was most satisfactory, the problem at Battersea is more difficult and has to contend with a doubling of the ash content of the coal since before 1939.

The high demand for cement has continued, and all kilns have operated at full output even when their associated dust-arrestment plants are undergoing repair, so that it was not surprising, especially in view of the fine summer, that there were complaints from most cement-making areas. The inspectorate continued its general policy of ensuring that all de-dusting plant is kept in as efficient a state as possible, that shut-downs are kept to the absolute minimum and that standards of supervision and "housekeeping" are as high as possible. The operation and maintenance of electrical precipitators still give real difficulty at many works. The production of sulphuric acid as monohydrate reached a record in Britain of 1,899,000 tons, an increase of 61,000 tons over 1954, and there was a spectacular increase in the usage of anhydrite for the dual production of sulphuric acid and cement clinker—from 177,000 tons in 1954 to 382,000 tons—and this process involves a serious problem of mist in the final escapes to air.

The Chief Inspector for Scotland reports no change in the number of works (82) registered under the Acts; but the number of processes operated increased by three to 119. On the 195 visits made to registered works, 92 chemical tests of flue emission were made involving the analysis of 116 samples, 14 by the Government Chemist; a further 166 visits were made which were not directly related to the provisions of the Acts. The Chief Inspector remarks that recent research has thrown more light on the dispersal of gases and dust from chimneys, and it seems desirable that the results of this work should be applied more generally, if only to test their validity; he cites an instance in which recently published work on dispersal of dust from high chimneys was particularly useful in connexion with dust emission from a power station in the west of Scotland which is fired with pulverized fuel.

BIRD SEMANTICS

Most birds have a rudimentary language. A crow, for example, gathers its flock by uttering a distinctive 'assembly call' and disperses it by squawking an 'alarm call'. The flock will respond to tape recordings of these calls just as it does to the cries of a live bird.

Two research groups, one in the United States, the other in France, recently exchanged tapes on which they had recorded the calls of their native crows. Their object was to learn whether French 'crows' (rooks, jackdaws and carrion crows) would understand the language of the American eastern crow, and vice versa (*Sci. Amer.*, August 1956). Roosting French 'crows' consistently ignored the alarm call of American crows; but more than half the French birds were aroused by the broadcast of an American 'gathering' call. American crows were wholly unmoved by the plaintive cries of nestling rooks or the strident assembly call of adult jackdaws—commands which all three species of French crow invariably obey.

In a further experiment, the French investigators broadcast the food-finding and alarm calls of the American herring gull, a bird that also dwells on French coasts. The French gulls paid no heed to the American calls. From these experiments the investigators concluded that birds learn the language of their kind from older birds of their own group. The investigators included R.-G. Busnel, J. Giban and Ph. Gramet, of the French National Institute for Agricultural Research; the Americans were Hubert and Mabel Frings and J. Jumber, of Pennsylvania State University and the Mount Desert Island Biological Laboratory.

PAN INDIAN OCEAN SCIENCE CONGRESS

THE Pan Indian Ocean Science Association was formed in January 1951, at Bangalore, India, when thirty-six delegates representing nine countries met for the first Pan Indian Ocean Science Congress. The 1951 meeting was mainly devoted to drafting a constitution for the Association, and in arranging working committees in each of the member countries. Much consideration was also given to the major scientific problems affecting these nations. This initial survey enabled the national committees during the 1951–54 inter-congress period to prepare many reports on problems of the Indian Ocean zone and on researches which had been carried out upon them. These reports provided material for the symposia and discussions of the second Pan Indian Ocean Science Congress, which was held in Perth, Western Australia, in August 1954 and attended by 527 people. Indonesia and Pakistan were admitted to membership of the Association at Perth; the other member countries are Australia, Burma, Ceylon, France, India, Madagascar, Malaya, the Netherlands and Portugal.

The Proceedings of the Congress, which appear in eight volumes, contain some of the original papers and an account of some of the discussion. The first volume contains the whole presidential address and also gives details of the constitution and membership of the Congress as well as recommendations by the whole Congress or by the separate sections of the physical sciences; biological sciences; geological sciences; agricultural sciences; economics, education, and social sciences; geography and oceanography and human ecology. The scientific papers of the various sections are set out in the remaining volumes.

The president at Perth was Prof. A. P. Elkin, professor of anthropology in the University of Sydney, who spoke about "The Natural History of Man".

The recommendations of the Congress give an indication of the wide-ranging scope of its deliberations and of the practical efforts made to secure co-operation in research and development for the whole area. Among the many important recommendations were the following.

Recognizing the importance of the preparation of detailed information on the distribution of plants and animals, particularly in coastal areas, the Congress recommended that co-operation be instituted with the Pacific Science Association in a similar project which the latter is undertaking, and that in future work more attention be devoted to the study of biocœnoses.

The Congress also recommended that continuous records of temperature, rainfall, humidity and sunshine for a range of type localities in each country be kept, and directed attention to the need for international agricultural quarantine regulations for the Indian Ocean region.

The Congress recommended collaboration in the preparation of climatic and other maps on a uniform basis, so that results obtained in any one country could be applied more systematically in other countries; collaboration in the collection of wild and cultivated forms of economic plants indigenous to the Indian Ocean region; collaboration in plant exploration in extra-regional areas of special significance for the Indian Ocean countries; and visits by and interchange of agricultural scientists of the Association countries with a special knowledge of plant introduction requirements and possibilities and thus able to stimulate useful exchanges of plant material.

Recognizing that the improvement of tropical grasslands offers great scope for improving the world's food supply and involves problems common to all Indian Ocean countries, the Congress recommended that information gained in these countries on this subject should be interchanged.

As mixed farming can play an important part in the development of tropical agriculture, the Congress recommended that there be concerted action in research on problems relating to this system of land use in the Pan Indian Ocean area.

The Congress suggested that the Association should undertake the preparation of a general handbook presenting in broad terms the present state of scientific knowledge of the Indian Ocean area as a whole; while Unesco was to be asked to assist in the development of facilities within existing stations of the area to train and interchange personnel.

The Unesco proposal to create a legally constituted inter-governmental organization for oceanographic research in the Indo-Pacific region was strongly supported.

Food problems were discussed, and the Congress recommended that exchange of information on the principles of food management should be organized; that a study of food habits and 'food fads' be made in the area; and that a study of elementary nutrition be included in primary education programmes. After considering tuberculosis and leprosy, the Congress recommended that an attack on socio-economic conditions, particularly housing, should be considered as the most effective factor in tuberculosis control and that primary education in living habits, with particular reference to spitting, and secondary education to produce trained personnel, should be emphasized in any tuberculosis-control programme; the institution of an effective method of prevention of leper migration to unaffected areas was recommended.

The secretary of the Congress is Prof. A. D. Ross, from whom at "Balnagown", Golf Links Road, Albany, Western Australia, copies of the full Proceedings may be obtained, price 37*s*. 6*d*. The next Congress is to be held at Tananarive, Madagascar, in September 1957.

METHODS FOR THE STUDY OF HUMAN RELATIONS IN INDUSTRY

DURING the War and the post-War period, in Western countries and more especially in the United States, there has been a gradual awareness of the need for a more adequate social-psychological approach to problems of human motivation and adjustment in industry. This approach is concerned with the satisfactions and motivations existing among the members of different groups in industries and how these can be improved by suitable changes in the groups and organizational structure. Psychology has contributed the maximum toward the development and refinement of techniques for study of human relations problems.

The psychologist, in his study of these problems, uses one or more of three distinct approaches. These are: (1) the attitude survey approach; (2) the group dynamics approach; and (3) the clinical psychology approach.

Each technique has its usefulness in its own field. The survey technique is particularly useful in the discovery of principles underlying problems of organizing and managing human activity. The Survey Research Centre of the Institute for Social Research at Ann Arbor is using it with advantage for the study of "social and interpersonal determinants of organizational effectiveness and employee satisfaction".

The group dynamics approach, developed on the conceptualizations of Kurt Lewin, is specially useful for the understanding of determinants of inter-group relations and of relations among members of a group. This approach, in combination with the sociometric technique, has made possible careful observation and analysis of group behaviour.

Psychotherapy is highly useful in specific cases; but its utility lies perhaps not in any improvement of human relations in industry by treating all those suffering from emotional maladjustments (there are not enough therapists for that even in the United States), but in analysing the effects of different types of personalities on the organizational structures set up by them, the top man's methods of dealing with people in the organization and the way it influences their attitude.

The ultimate object of various studies made along the above lines is to have an integrated theory of organized human effort which will be useful to society in general and to industry in particular. This can best be achieved by a close integration of ideas from different social sciences, psychology, sociology, economics, anthropology, etc. So far as human relations in industry are concerned, approaches are being made from different sides; substantial inter-professional collaboration is yet to be achieved.

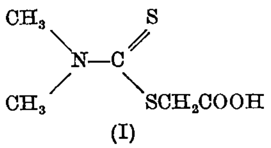
Studies based on the above techniques and the changes based on findings from such studies that the psychologist attempts to introduce in the organizational structure carry some implicit value assumptions of what is desirable, what is good. As yet, little attempt has been made to make them explicit or justify them. Harish Chandra Ganguli suggests that this is all the more necessary for psychologists of countries other than the United States who try to use these techniques mostly developed in America and permeated with American values in a setting culturally and socially very much different from that of the country of origin (*Sci. and Cult.*, 21, No. 12; June 1956).

PLANT GROWTH-REGULATING ACTIVITY IN CERTAIN CARBOXYLIC ACIDS NOT POSSESSING A RING STRUCTURE

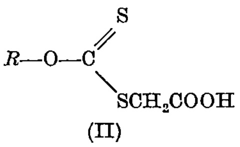
By DR. C. H. FAWCETT, PROF. R. L. WAIN and DR. F. WIGHTMAN

Agricultural Research Council Unit on Plant Growth Substances and Systemic Fungicides, Wye College, Kent

CHEMICAL structure in relation to plant growth-regulating activity of carboxylic acids has been the subject of much research over the past twenty years, and until recently it was considered that, in addition to the —COOH group, another essential requirement for activity was an unsaturated ring structure[1]. The discovery by van der Kerk and co-workers[2] that carboxymethyl dimethyldithiocarbamate (I) and certain of its analogues can show appreciable plant growth-regulating activity indicates that an unsaturated ring system may not be essential. These workers suggested, however, that the activity observed in these compounds is associated with the N—C bond acquiring double-bond character due to internal electron shifts, thus resulting in a type of 'ring' system[2]. This possibility has since been questioned[3].



(I)



(II)

We have synthesized a series of carboxymethyl O-alkyxanthates (II) and the tertiary butyl derivative ($R = (CH_3)_3C$—) was found to be significantly active in promoting the growth of 1-cm. wheat coleoptile sections (Table 1). The technique was exactly as described for the *Avena* cylinder test[4] except that wheat coleoptiles (var. Eclipse) were used. The fact that in the xanthates the O—C bond acquires comparatively little double-bond character[3] (as in the canonical form  $R{-}\overset{(+)}{O}{=}\overset{\overset{(-)}{S}}{\overset{|}{C}}{-}S{-}$) provides further evidence that a ring or partial ring is not essential for growth-regulating activity. Again, the small but significant activity reported by Bennet-Clark for dimethylacetothetin chloride[5] is consistent with the view that a ring system need not be present. The interesting possibility has been raised that the activity of the thetin is related to its known behaviour as a methyl donor[5]. Betaine hydrochloride, known to be less active in transmethylation, is inactive in the wheat test (Table 1).

In a study on the growth-promoting activity of chloro- and methyl-substituted acetic acids in the wheat coleoptile test, significant activity was found in a number of instances. Thus, for example, all three chloro-acids were active (Table 1); though no activity was shown by these or any other compounds of this group in the pea curvature test. The slight activity previously reported for trichloroacetic acid in the pea test[6] has not been observed in the present work.

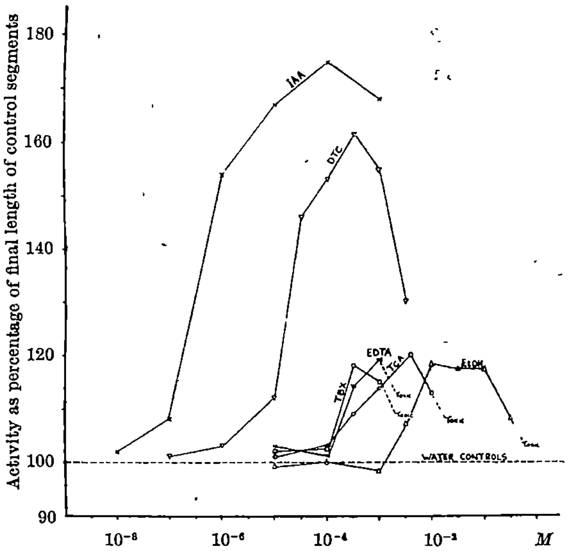


Fig. 1. Activity in the wheat cylinder test after 24 hr. of certain non-ring compounds relative to 3-indolylacetic acid. All acids tested as the sodium salts (EDTA as the tetra-salt). DTC, carboxymethyl dimethyldithiocarbamate; TBX, carboxymethyl O-*tert*-butylxanthate; EDTA, ethylenediaminetetraacetic acid; TCA, trichloroacetic acid; EtOH, ethyl alcohol

The first suggestion that chelating agents may show plant growth-regulating activity was made by Bennet-Clark at the Wye Symposium in 1955[5]. It was shown that ethylenediaminetetraacetic acid is capable of promoting slight extension growth both in oat and wheat coleoptile tissue, and this was attributed to a chelating mechanism whereby the calcium/pectin relationship in the cell wall was affected. The activity of ethylenediaminetetraacetic acid was independently observed by Heath and Clark[7], who also favour a chelation hypothesis. In support of this, they showed that whereas a number of other chelating agents possessed significant activity in the wheat cylinder test, various compounds not recognized as chelators possessed negligible activity. The suggestion was also made that highly active auxins such as 3-indolylacetic acid and 2 : 4-dichlorophenoxyacetic acid might owe their biological activity to chelating properties. In view of the limited capacity of these molecules to chelate with metals and their very high growth-regulating activity, this would appear unlikely. Furthermore, chelation cannot be a universal mechanism leading to all types of growth response, since in the pea curvature and tomato leaf epinasty tests, in which 3-indolylacetic acid and 2 : 4-dichlorophenoxyacetic acid are extremely active, ethylenediaminetetraacetic acid has been found to be completely inactive.

It is important that the activity of all these non-ring compounds should be seen in the right perspective. Heath and Clark[7] in one experiment with wheat coleoptile sections found ethylenediaminetetraacetic acid at 10^{-5} *M* gave practically the same increment of growth, compared with controls, as 3-indolylacetic acid at the same molar concentration. In a second experiment, the response to ethylenediaminetetraacetic acid was just significantly less than that shown by 3-indolylacetic acid. In the present work, using a different technique, ethylenediaminetetraacetic acid was found to be a much less active growth substance than 3-indolylacetic acid (Table 1, Fig. 1), a result previously found by Bennet-Clark using oat coleoptile segments[5].

It therefore became necessary to carry out further experiments in which the activities of ethylenediaminetetraacetic acid and 3-indolylacetic acid were compared after treatment periods of 24, 36 and 48 hr. The analytically pure compounds were tested both as the free acids and as their sodium salts, all four salts being included in the case of ethylenediaminetetraacetic acid. The results for the salts were similar to those obtained with the acids and, furthermore, no significant differences were observed

Table 1 THE ACTIVITY OF CERTAIN CARBOXYLIC ACIDS IN THE WHEAT CYLINDER ELONGATION TEST*

Formula of compound	Concentration in p.p.m. 0·1	1	10	100	500	1,000

† Tetra-sodium salt.

in the results obtained for the various treatment periods. It is apparent from Fig. 1 that ethylenediaminetetraacetic acid is very much less active for promoting extension growth in wheat coleoptiles than is 3-indolylacetic acid. Indeed, in these experiments ethylenediaminetetraacetic acid showed the same low order of activity as trichloroacetic acid and carboxymethyl O-*tert*-butylxanthate (Fig. 1). In view of the fact that these three non-ring compounds are completely inactive in the pea curvature test and that their capacity to induce slight growth responses in wheat coleoptile tissue is only revealed at near-toxic concentrations, it is possible that the compounds are not acting as true 'growth substances'. In agreement with this, the shape of the growth/time curves at optimum concentrations indicates that the pattern of growth is not typical of a normal auxin response. The action of these substances may well depend upon changes in membrane permeability and cell wall structure resulting from sub-acute toxicity.

To examine this possibility further, a study was made of the behaviour of ethyl alcohol in the wheat test. This compound showed the same low order of growth response (Fig. 1), and, furthermore, the highest activity was revealed at a concentration just below the level at which toxic symptoms were observed. Moreover, the type of elongation observed was typical of that shown by ethylenediaminetetraacetic acid, trichloroacetic acid and the xanthate and different from that induced by sugars and other respiratory substrates. This activity of ethyl alcohol has been confirmed a number of times, and it is suggested that this provides a further example of the 'non-typical' growth-regulating activity discussed above. On the other hand, certain dimethyldithiocarbamate derivatives (I), for example, can show appreciable activity in the wheat test (Table 1, Fig. 1), and since such compounds are also active in the pea and tomato-leaf epinasty tests it is probable that this type of non-ring structure is capable of inducing a true auxin response.

INHIBITION OF PLANT CYTOCHROME OXIDASE BY BICARBONATE

By GENE W. MILLER and PROF. HAROLD J. EVANS

North Carolina Agricultural Experiment Station, Raleigh, N.C.

THE concentration of carbon dioxide in equilibrium with bicarbonate in the soil has been recognized as an important ecological factor for many years[1]. Recent experiments by Thorne *et al.*[2] have indicated that the level of bicarbonate in nutrient media is positively correlated with the incidence of lime-induced chlorosis. Bean plants grown in nutrient cultures in which *p*H and bicarbonate concentrations were varied by controlling the carbon dioxide pressure of the aeration stream developed chlorosis at the high bicarbonate levels regardless of the *p*H of the solutions. Further experiments[3] indicated that the inhibition by bicarbonate of the respiratory rates of roots from chlorosis-susceptible species was greater than that of the roots from chlorosis-resistant species. A study[3] of the carbon monoxide inhibition of oxygen uptake provided indirect evidence that cytochrome oxidase was the dominant terminal oxidase in the bicarbonate-susceptible plants, and possibly was the factor affected by bicarbonate salts.

The experiments reported herein provide direct evidence that bicarbonate is an inhibitor of cytochrome oxidase from certain higher plant species. These experiments were conducted in conjunction with a more detailed study of the stimulatory effects of various salts on cytochrome oxidase activity.

In the experiment illustrated in Fig. 1 the effect of sodium bicarbonate on the activity of cytochrome oxidase from two species was compared with that of sodium chloride on the activity of the enzyme. Particulate preparations containing cytochrome oxidase were made from the roots of spinach (*Spinacia*

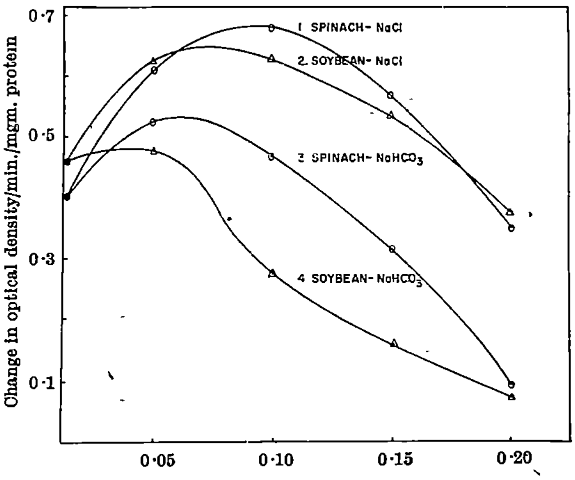

Fig. 1. The effect of sodium bicarbonate compared to sodium chloride on cytochrome oxidase activity of soybean and spinach roots. The complete system (curve 1) contained 50 μmoles tris buffer at *p*H of 8·8, 0 051 μmole reduced cytochrome *c*, extract of particulate material from spinach roots and concentrations of sodium chloride indicated in a final volume of 1 ml. Curve 2, identical reaction mixture with the exception that the extract was obtained from soybean roots. Curve 3, the assay mixture was identical to that for curve 1 with the exception that sodium bicarbonate was added instead of sodium chloride. Curve 4, the reaction mixture was identical with that for curve 2 with the exception that sodium bicarbonate replaced sodium chloride. Reactions were started by addition of extract containing 0·1–0 2 mgm. protein, and stirred prior to each reading to avoid errors due to the settling of particles in the cuvette

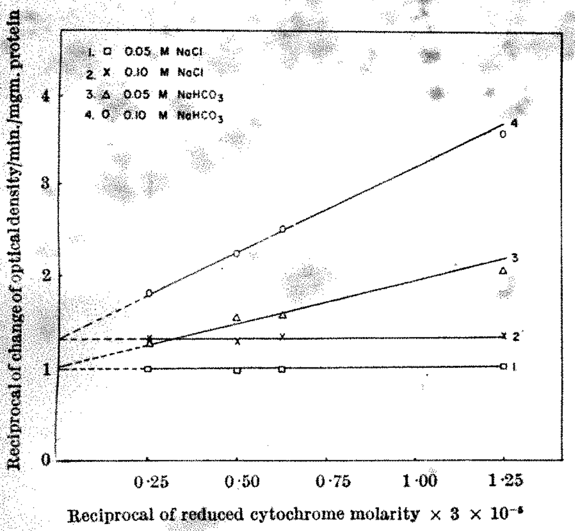

Fig. 2. Lineweaver–Burk plot of the inhibition of cytochrome oxidase activity of soybean roots by sodium bicarbonate. Assay mixtures in a final volume of 1 ml. contained 50 μmoles tris buffer at *p*H of 8·8, desired concentration of reduced cytochrome *c*, the indicated type and concentration of salt and extract containing 0·12 mgm. protein. Readings were taken every 10 sec. and enzyme activity calculated as the change in optical density per min. per mgm. protein using only the linear portion of optical density change per unit of time

oleracea L., variety Bloomsdale) or soybean (*Glycine max* Merr., variety Ogden) plants 6–30 days old as previously described[4], with the exception that the isolation medium contained 0·05 *M* tris-hydroxymethyl-aminomethane buffer at *p*H 7·5 instead of phosphate buffer. Reduced cytochrome *c* was prepared chemically by the use of sodium hydrosulphite[4] and the assays were determined spectrophotometrically at 550μ with a Beckman *DU* spectrophotometer[4]. The enzyme activity is indicated as the decrease in optical density between 15 and 75 sec. after the reaction was started by the addition of enzyme. Under the conditions of the experiments, the oxidation rates were linear for two minutes after the reactions had begun. The protein content of the extracts was determined by the use of Folin's phenol reagent[5].

The curves in Fig. 1 show that cytochrome oxidase from the roots of both spinach and soybean plants is stimulated by concentrations of sodium chloride up to 0·1 *N*; but concentrations greater than this resulted in decreases in activity. The influence of variable concentrations of sodium nitrate and sodium sulphate was practically identical to that of sodium chloride. It is apparent from Fig. 1 that various concentrations of bicarbonate at *p*H values comparable to those where chloride salts were used inhibited cytochrome oxidase activity from 20 to 75 per cent, depending on the bicarbonate concentration. This inhibitory effect also has been observed with cytochrome oxidase preparations from oat and tobacco plants and from pig heart. The inhibitory action of bicarbonate has been observed in assay mixtures adjusted to *p*H 7·8 by use of tris-hydroxyaminomethane buffer and carbon dioxide. The inhibition is not limited, therefore, to the high *p*H conditions used in the experiment shown in Fig. 1.

The influence of sodium bicarbonate on cytochrome oxidase activity of soybean root extracts at various reduced cytochrome *c* concentrations was determined, and the reciprocals of enzyme activities plotted against the reciprocals of reduced cytochrome *c* concentrations according to the method of Lineweaver and Burk[6] (Fig. 2). The results from assays containing concentrations of 0·05 *M* (curve 3) and 0·10 *M* (curve 4) sodium bicarbonate were compared with those from assays containing equivalent amounts of sodium chloride (curves 1 and 2). These results indicate that sodium bicarbonate is a competitive inhibitor of cytochrome oxidase.

Since it was apparent that bicarbonate inhibited cytochrome oxidase *in vitro* and since evidence in the literature indicated that excessive bicarbonate in culture media is detrimental to plant growth and is associated with chlorosis of leaves, it was deemed necessary to determine whether the addition of bicarbonate to culture solutions would influence the activity of cytochrome oxidase in tissues. To test this possibility, soybean plants of the Ogden variety were grown in pots of washed quartz sand in the greenhouse. Seven seven-day-old seedlings were transferred to each of twelve polyethylene pots of quartz sand. The pots held a volume of 6 litres and each was equipped with a drain hole in the bottom. Four treatments replicated three times were applied to the cultures in a randomized block experiment. The treatments indicated in Table 1 consisted of 0·008 *M* and 0·016 *M* sodium bicarbonate and 0·008 *M* and 0·016 *M* sodium chloride + sodium hydroxide. The variable culture treatments were added to a standard Hoagland nutrient solution, and the soybean cultures were flushed with the appropriate solutions three times daily. The *p*H of the effluent from cultures receiving sodium chloride + sodium hydroxide ranged between 7·5 and 7·7 and that of the effluent from cultures receiving sodium bicarbonate ranged between 7·6 and 7·9. After 25 days the plant receiving bicarbonate in solutions developed a chlorosis of leaves. At that time roots were harvested and extracts prepared from them by the method indicated in the experiment reported in Fig. 1. Results of assays presented in Table 1 show that the extracts from plants receiving the bicarbonate treatments were significantly lower in cytochrome oxidase activity than extracts from plants grown with comparable concentration of sodium added as the chloride and hydroxide. The inhibitory effect of the 0·008 *M* sodium bicarbonate treatment on the enzyme activity was significant at the 1 per cent level and the effect of the 0·016 *M* sodium bicarbonate

Table 1. THE EFFECT OF SODIUM BICARBONATE IN CULTURE SOLUTIONS ON THE CYTOCHROME OXIDASE ACTIVITY OF EXTRACTS FROM ROOTS OF SOYBEAN PLANTS

Culture treatment		*p*H of culture solution	Cytochrome oxidase activity†	Appearance of chlorosis
NaCl + NaOH*	$NaHCO_3$			
M	*M*			
0·008	0·000	7·7	1·13	–
0·000	0·008	7·7	0·67	+
0·016	0·000	7·8	0·92	–
0·000	0·016	7·8	0·60	+
L.S.D. (1 per cent			0·34	
L.S.D. (5 per cent)			0·23	

* Treatments containing no sodium bicarbonate were adjusted to the desired *p*H with sodium hydroxide, and sufficient sodium chloride was added to give a concentration of sodium comparable to the bicarbonate treatments.

† The reaction mixture in a final volume of 1 ml. contained 50 μmoles tris buffer at *p*H 7·5, 0·051 μmole reduced cytochrome *c* and extract prepared from roots of soybean plants grown with the various treatments and containing from 0·08 to 0·09 mgm. protein. Results are means of duplicate determinations from three replicate cultures and are expressed as optical density change at 550 mμ per minute per mgm. protein.

treatment approached this level of significance. As indicated in Table 1, the plants supplied with sodium bicarbonate developed a chlorosis of leaves; but this symptom was not apparent with plants grown without bicarbonate. There was no influence of treatment on the total growth of plants. Other treatments not reported indicated that extracts from plants grown with culture solutions with various *p*H values were not significantly different in cytochrome oxidase activity.

From the above results it seems clear that excessive concentrations either *in vitro* or *in vivo* inhibit cytochrome oxidase activity. Since the inhibition is competitive in respect to reduced cytochrome *c*, the inhibition in living tissues containing relatively low concentrations of cytochromes may be considerably greater than that indicated from assays conducted with relatively high cytochrome *c* concentrations. Further experimentation may prove that the inhibition of cytochrome oxidase by bicarbonate is related to the inhibition by this ion of respiration of plant tissues[3]. Also, these results may have a bearing on the observations that bicarbonate induces the accumulation of organic acids in excised barley roots[7] and on the observation that the tissues of plants affected by lime-induced chlorosis contain excessive concentrations of organic acids[8].

A CYTOLOGICAL STUDY OF THE NEURONES OF *PATELLA VULGATA* BY LIGHT AND ELECTRON MICROSCOPY

By Dr. DENNIS LACY

Department of Zoology and Comparative Anatomy, St. Bartholomew's Medical College, London

AND

ROBERT HORNE

Cavendish Laboratory, Cambridge

In view of various conflicting reports on the cytology of neurones of Mollusca[1-8] a study has been made of neurones from the pedal, pleural and visceral ganglia of the common limpet *Patella vulgata* by both light and electron microscopy.

Observations by Light Microscopy

When cells were treated by Kolatchev's method for the Golgi apparatus (post-osmification for 24 hr.) two types of inclusions were revealed: lipochondria (lipochrome granules, neutral-red bodies) and Golgi apparatus. The lipochondria were spheroidal in form, ranged in colour from light to dark brown, and varied greatly in number in different neurones. In large cells they typically clustered around a well-defined, and approximately central, region which, from evidence presented mainly by electron microscopy, was identified as an active secretory zone and will be termed the *S* region (Fig. 1). The Golgi apparatus nearly always appeared as a network of fine strands and only occasionally as apparently discrete curved dictyosomes. Both networks and dictyosomes were black in colour. Associated with some of the networks and dictyosomes was a weakly osmiophilic, diffuse material identified as archoplasm. In large neurones the Golgi apparatus ramified the *S* region and was therefore generally distinct topographically from the lipochondria. In small neurones the Golgi apparatus occupied a small juxta-nuclear region. The latter probably corresponds to the *S* region of larger cells.

It is generally accepted that iron haemotoxylin and acid fuchsin will stain mitochondria after appropriate fixation. Bleached Kolatchev preparations were stained, therefore, with iron haemotoxylin, and Helly post-chromed sections with acid fuchsin. The iron haemotoxylin stained small granules and rods which varied considerably in number from cell to cell and which were generally situated towards the periphery of the *S* region and among the lipochondria. By a study of individual cells both before bleaching

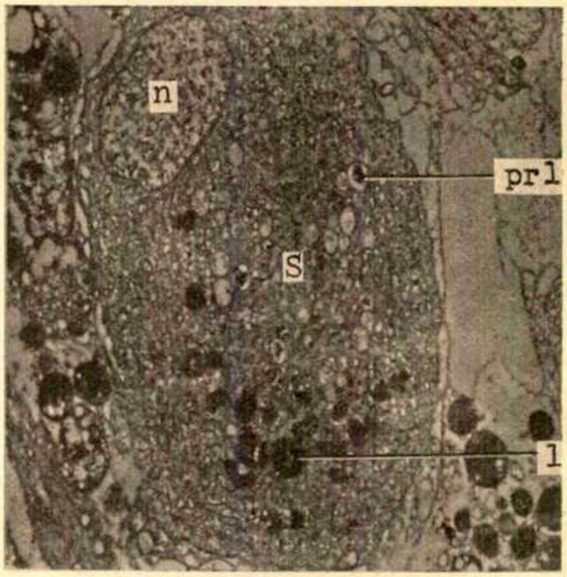

Fig. 1. Low-power micrograph showing the '*S*' region. Several pro-lipochondria (*prl*) and lipochondria (*l*) can also be seen. *n* = nucleus. (× 6,000)

and after staining with iron haemotoxylin, it was established that the Golgi apparatus is definitely not an artefact caused by the over-impregnation of mitochondria as maintained by Thomas[5].

In Helly preparations the acid fuchsin stained small granules and rods (similar to those revealed by iron haemotoxylin) and, to a less extent, the lipochondria. Some of the small granules were larger than others. Both in this respect and in their staining reaction they seemed to represent a stage in the formation of the lipochondria. Thus the acid fuchsin was apparently staining mitochondria, developing lipochondria, and mature lipochondria. (It is probable that the iron haemotoxylin also stained the mitochondria and developing lipochondria.) In cells containing many small fuchsinophil granules there were few lipochondria and vice versa.

Within the limits of resolution of the light microscope, the cell body of these neurones extended into a single nerve process. The position of the nucleus relative to the process was very variable. Often it lay either near the process or, on the other hand, at the extreme opposite end of the cell body. Rarely did we see a nucleus in the central position as so often depicted for cells of this kind[1-7]. Each nerve process passed from the outer (cortical) region of each ganglia into the central (medullary) part, where it met numerous other nerve fibres.

Each nucleus usually contained a single prominent nucleolus which was intensely osmiophilic and stained strongly with iron hæmotoxylin, acid fuchsin, and methylene blue. When Champy post-chromed preparations (gelatine embedded) were stained with acid fuchsin a few minute granules were seen in the nucleoplasm in addition to the nucleolus.

Kolatchev preparations not only revealed the lipochondria and Golgi apparatus but also fine fibrils within the nerve fibres.

Observations by Electron Microscopy

Studies on neurones treated by Kolatchev's method, or on those fixed in buffered osmium tetroxide and examined at high resolution with a Siemens Elmiskop 1, substantiated and extended the observations recorded above. The following account refers to material fixed in buffered osmium tetroxide except when stated otherwise.

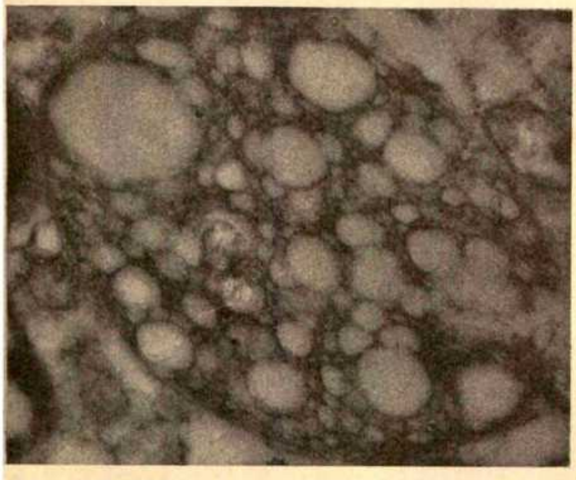

Fig. 2. Micrograph showing the ultrastructure of a lipochondrion. The internal network of membranes divides the inclusion into a number of osmiophobic compartments. (× 40,000)

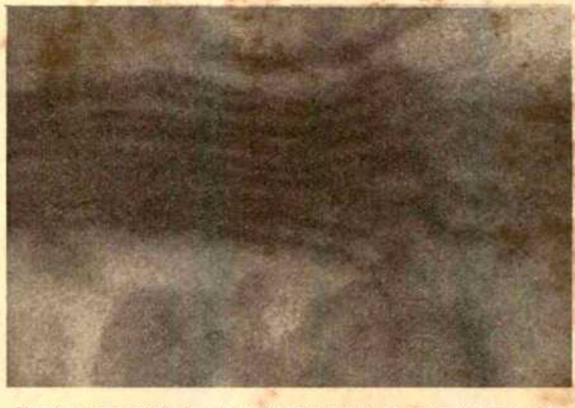

Fig. 3. Micrograph showing paired Golgi membranes. (× 120,000)

The lipochondria, which generally appeared homogeneous in light microscopical preparations, were either homogeneous or consisted of an elaborate internal network of membranes (Fig. 2). The Golgi apparatus had essentially the same ultra structure as in many kinds of vertebrate cells[9,10]. It consisted of paired anastomosing membranes which usually enclosed an inner dense (osmiophilic) substance, a vacuolar (osmiophobic) material lying within dilations of the paired membranes, discrete vacuoles, and small vesicles (Fig. 3). The networks and dictyosomes seen in light microscope preparations were due to the impregnation of the paired membranes and inner substance; the archoplasm probably resulted from the impregnation of the Golgi vesicles. The mitochondria were generally few in number and were either rod-like with numerous cristae[11] or spheroidal with few cristae (see below).

The *S* region was seen with great clarity (Fig. 1). Within this region was the Golgi apparatus, occasional rod-like mitochondria, and numerous spheroidal bodies. The last-named were generally smallest in the centre of the *S* region and largest towards its periphery, where they lay among the lipochondria. Some of the spheroids were identified as mitochondria although the limiting membrane was not always completely double. Cristae were few and small, and the matrix was osmiophobic. The majority of the spheroids possessed only a single external 'limiting' membrane, an internal coiled membrane, and an inner substance containing various amounts of a very dense (osmiophilic) material. The appearance of the last-named inclusions strongly suggested that they represented stages in the formation of the osmiophilic lipochondria. Provisionally they will be referred to as *pro-lipochondria* (Fig. 1). The evidence both from light microscopy (*vide* results with acid fuchsin above) and electron microscopy suggested that the pro-lipochondria were of mitochondrial origin. It may be emphasized here that lying between all the spheroids (mitochondria and pro-lipochondria) were masses of Golgi vesicles. This may suggest that the Golgi apparatus plays some part in the formation of the lipochondria.

Another kind of cell inclusion, lying below the limits of resolution of light microscopy, was revealed by the electron microscope. This inclusion consisted of a small vacuole with a dense granule embedded in its periphery. Such structures were observed generally towards the periphery of the cell body, although some were seen also in the *S* region.

The cells did not contain a highly developed system of ergastoplasmic membranes[12]. Typically they bordered lamelliform or large vesicular masses of ergastoplasm. Occasionally the membranes formed conspicuous whorl-like figures similar to those described by Palay and Palade[13] in vertebrate neurones. Some cytoplasmic particles[14] were in contact with one side of the ergastoplasmic membranes except when the latter were whorl-like in form. Numerous such particles lay free in the cytoplasmic matrix.

Each neurone was bounded by a single membrane. Frequently it appeared as if two membranes were present. However, in such cases the outer membrane belonged either to an adjacent cell body or nerve fibre. Each nerve fibre contained a variable number of neurofibrils (individually below the limits of resolution of the light microscope) and small mitochondria. In Kolatchev preparations studied by electron microscopy the osmium either was deposited heavily on single neurofibrils or, more usually, between them. In either way this accounted for the appearance under the light microscope of fine fibrils in nerve fibres treated by Kolatchev's technique. In material fixed in buffered osmium tetroxide, tangled masses of neurofibrils were observed passing around vacuolated bodies and small vesicles. It is possible that the vacuolated bodies and vesicles may serve as the nidus for the formation of the neurofibrils.

Both the lipochondria and the vacuole-granule inclusions described above were observed in nerve fibres. It appears, therefore, that each is a definite secretory product of the neurones. It is of particular interest that lipochondria appear to be formed in essentially the same way as are zymogen granules in exocrine cells of the pancreas[15,16]. Thus a common method of synthesizing secretion products apparently exists in such diverse types of cells as the neurones of a gastropod and pancreas cells of mammals.

We wish to express our appreciation to Drs. A. J. Marshall and V. E. Cosslett for their interest and encouragement in this work and to Mr. G. Rogers for his help in the cutting of ultra-thin sections. One of us (R. H.) is indebted to the Agricultural Research Council for financial support.

ROLE OF OXYGEN IN MODIFYING THE RADIOSENSITIVITY OF *E. COLI* B.

By TIKVAH ALPER and DR. P. HOWARD-FLANDERS

Medical Research Council Experimental Radiopathology Research Unit, Hammersmith Hospital, London, W.12

IN the course of X-ray experiments on *E. coli* B., it was found that the radiosensitivity of the bacteria was increased by oxygen concentrations as low as 1 μmole/l. This is very small compared with the concentration required to effect a similar change in other materials used in radiobiological experiments[1,2]. Oxygen concentration is measurable only in the fluids surrounding the cells or tissues concerned, and the assumption that it is the same within the cells seems best justified for micro-organisms, singly dispersed in a medium supplied with oxygen at a rate far exceeding that required for respiration. The effect of varying the oxygen concentration on the radiosensitivity of *E. coli* B. has therefore been investigated by irradiating very dilute suspensions while the required gas mixture was passed through the suspending medium in a vigorous stream of fine bubbles.

The bacteria were in the stationary phase, harvested 16–20 hr. after inoculation, from unaerated nutrient broth which then contained about 2×10^8 organisms/ml. The suspensions for irradiation were prepared by centrifuging the cultures, washing three times and resuspending in buffered saline (sodium chloride 0·13 *M*, phosphate buffer 0·02 *M*, *p*H 7·0); aliquots were then used for making up suspensions in buffered saline at the dilutions required. Irradiations were carried out at 20° C. with 200 kV. X-rays filtered by 2 mm. aluminium, at 2,000 rads/minute. 'Survivors' in the bacterial population were defined as those bacteria which retained the ability to form macrocolonies on nutrient agar plates incubated at 37° C. Survival curves were found to be exponential in all experiments. The radiosensitivity was defined as the slope of the line relating the logarithms of survivors to the dose. The radiosensitivity was found to be independent of the concentration of bacteria between 6×10^3 and 2×10^8 organisms/ml. and also independent of the respiration-rate. It appeared to depend only on the oxygen concentration at the time of irradiation. The survival curves were identical for bacteria which were held anaerobically from the time of harvesting until irradiation commenced, and for those which, in dilute substrate-free suspension, had been exhausted by oxygen bubbling at 30° C. for 1½ hr. Moreover, radiosensitivity was the same for suspensions which were free from substrate and those which contained potassium succinate at 0·01 *M*. The effect of the succinate on respiration-rate was demonstrated by measurements on a dense washed suspension of *E. coli* B. The rate of oxygen uptake was increased by a factor of 5 when succinate was added after 40 min. of endogenous respiration (we are indebted to Dr. F. A. Holton for making this measurement).

The relationship between radiosensitivity and oxygen concentration was determined by establishing survival curves under nitrogen, oxygen and a range of nitrogen – oxygen mixtures. A typical set of survival curves is shown in Fig. 1. The variation of radiosensitivity with oxygen concentration is shown in Fig. 2. The solid line (curve A) represents the equation

$$\frac{S}{S_N} = \frac{m[O_2]+K}{[O_2]+K} \qquad (1)$$

where S_N is radiosensitivity in the absence of oxygen; $[O_2]$ is oxygen concentration in micromoles of oxygen per litre; S is radiosensitivity at an oxygen concentration $[O_2]$; m and K are constants, respectively 2·9 and 7·2 micromoles/litre for curve A.

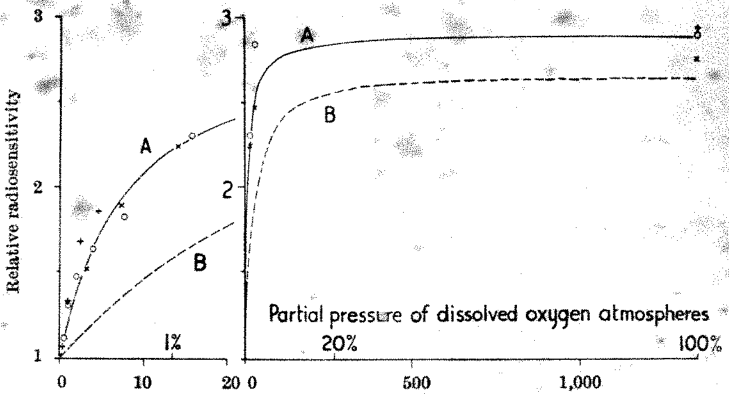

Fig. 2

The relationship between radiosensitivity and oxygen tension in other materials could also be described by an equation of the form given. In many cases the value of the constant m is close to 3 [1,2]. The value of K obtained for *E. coli* B. is, however, considerably lower than that obtained by fitting equation (1) to various sets of data in the literature: for example, Conger's data[2] on ascites tumour cells are fitted by $m = 3·6$, $K = 135$ μmoles/l. It remains to be determined whether K does in fact vary over a wide range, depending on the material and the test of damage, or whether the low value obtained in these experiments reflects the fact that oxygen pressure in the cells is more nearly the same as that measured than has been the case in the conditions of other experiments.

A relationship of the type expressed by equation (1) can be derived from various mechanisms which might be postulated to account for the oxygen effect.

HO_2 radical hypothesis. It has frequently been suggested that primary damage to biological targets may occur by a mechanism analogous with that which increases the yield of oxidation products in aqueous solutions irradiated in the presence of oxygen. This mechanism is believed to be the conversion of hydrogen to HO_2 radicals if oxygen is present. The oxidation of ferrous ions in 0·8 N sulphuric acid has been investigated by Ebert[2]. Equation (1) fits his data well with $m = 2·7$, $K = 22·4$ μmoles/l., and curve B of Fig. 2 represents the equation with these constants. In the chemical system, it can be presumed that there is far less competition for hydrogen radicals than in the living cell, where there must be a great number of competing molecules. For example, Alper (unpublished work) has found that herring sperm deoxyribonucleic acid in aqueous solution is an extremely efficient scavenger of hydrogen radicals. It is to be expected that, to bring about a given change in radiosensitivity by means of HO_2 radicals, a higher oxygen concentration is needed in the presence of a radical-acceptor. If the mechanism for the oxygen effect is the same, the constant K of equation (1) should be higher, or at least not lower, in the living cell than in solutions free from organic solutes. As the opposite was observed, it appears to us unlikely that the enhancing effect of oxygen can be accounted for by HO_2 radicals effecting primary damage.

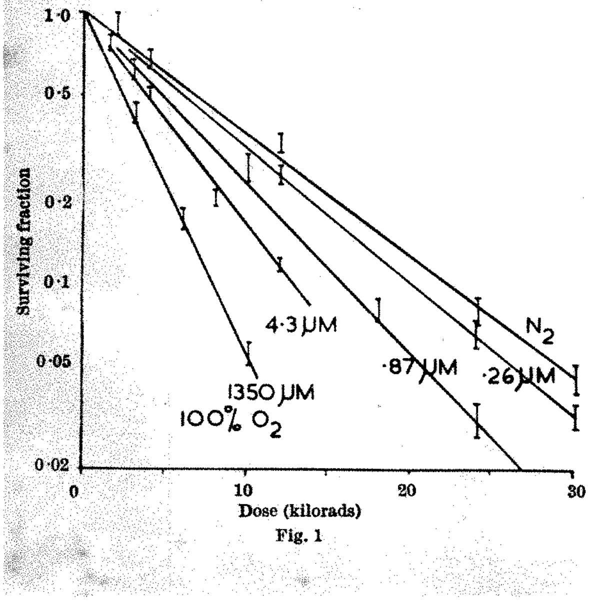

Fig. 1

Respiratory enzyme hypothesis. It is unlikely that radiosensitivity depends upon the state of the respiratory enzymes[3] as Longmuir[4] has shown that *E. coli* respire at half their full rate at an oxygen concentration of $2 \times 10^{-8} M$, whereas we found that more than 300 times as much oxygen was required to reach half the maximum radiosensitivity in *E. coli* B.

Direct effect hypothesis. In searching for an explanation of our observations on the oxygen effect on *E. coli* B., we have been led to postulate that the primary action of radiation in preventing cell multiplication is to ionize a vital target structure or molecule, which is then left in a highly reactive state, so that it will be involved in a chemical reaction within a very short time, probably less than a millisecond. The subsequent fate of the target molecule will depend on the nature of this reaction, which will affect the likelihood of its restoration to a functional state. If oxygen is present during irradiation, it will react with the ionized target and very much reduce the probability of restoration, so that a greater degree of damage will be apparent; but if it is admitted to the cell within a short time after the passage of the ionizing particle, it will be too late to take part in the reaction.

Output of Sympathin from the Spleen

Qualitative studies of the nature of 'sympathin', the vasopressor substance appearing in the venous blood after stimulating post-ganglionic adrenergic nerves, have shown that it consists of a mixture of adrenaline and noradrenaline. We have recently been investigating quantitative aspects of sympathin output from the spleen with particular attention to the effect of the frequency of stimulation.

The method used was to stimulate the splenic nerves of the chloralosed cat and to measure the sympathin, assayed as noradrenaline, appearing in the venous blood. Peart[1] and Mann and West[2] have shown that sympathin from the spleen is almost entirely noradrenaline. The spleen was isolated from the stomach, pancreas and omentum, but retained its own circulation. The venous blood from the organ could be temporarily diverted to a polythene cannula in the superior mesenteric vein by occluding the portal vein. The blood from the cannula was collected in chilled, silicone-coated centrifuge tubes containing solid heparin. These precautions prevented the formation of masking substances. The volume of the separated plasma was measured and its 'sympathin' content assayed on the pithed rat's B.P. The splenic nerves were stimulated with rectangular pulses known to be supramaximal. Since we were interested in the effect of the frequency of stimulation on the output, the total number of stimuli was kept constant at 200 stimuli irrespective of the frequency. Both adrenal glands were removed and both major splanchnic nerves cut.

The output of sympathin, expressed as output/stimulus, showed a remarkable variation with the frequency of stimulation. This is summarized in Fig. 1. At low frequencies, little sympathin appears in the venous blood; but the output rises sharply as the frequency increases, to reach a maximum at about 30 pulses per sec. In constructing this graph allowance must be made for variations in the plasma flow in the period of collection. The output of sympathin varies with flow, and if this is reduced the output falls. The figures used in this graph lie in the same range of plasma flow.

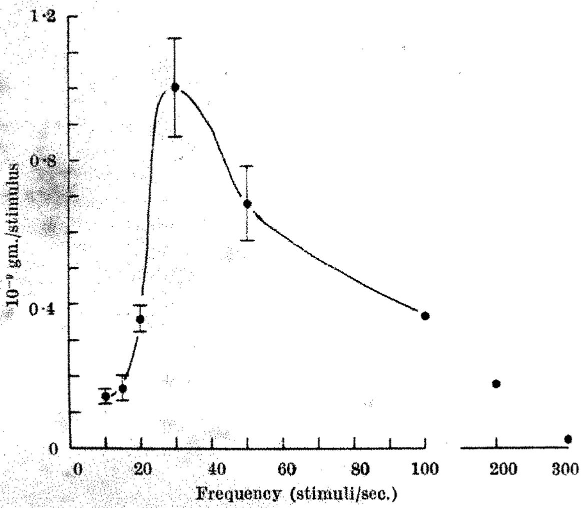

Fig. 1. Mean output/stimulus of 'sympathin' plotted against the frequency of stimulation. At all frequencies of stimulation the total number of pulses was 200. The vertical lines represent the standard errors of the means. Figures for 100, 200 and 300 pulses per sec. are single observations

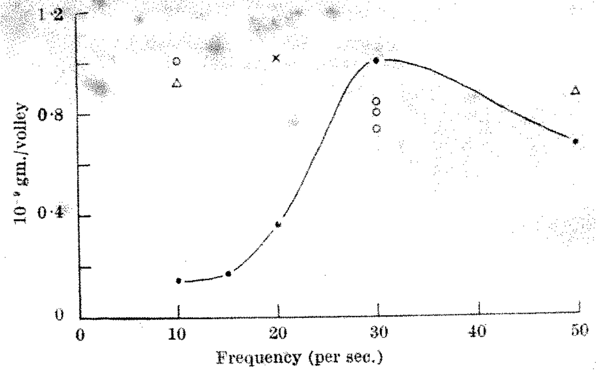

Fig. 2. First part of the graph in Fig. 1 with an extended scale for frequency. The individual results from three animals previously given 'Dibenamine' are shown. The output/stimulus at 10 pulses per sec. has increased and equals the maximum in the untreated animal. There is no obvious variation with frequency

Several explanations of this variation with frequency were possible. It might be that the more prolonged exposure to amine oxidase of the sympathin liberated at lower frequencies permitted a greater destruction of the active amine. This was tested by inhibiting the amine oxidase with isopropyl isonicotinyl hydrazine ('Marsilid'). The output before and after 'Marsilid' was the same.

Another possibility was that although the amount of sympathin released by each nerve volley was constant, the amount utilized by the tissue receptors was greater when the rate of release was slowed, that is, at low frequencies of stimulation. This was tested by blocking the tissue receptors with N.N. dibenzyl-β-chloroethylamine ('Dibenamine') and measuring the output/stimulus at varying frequencies. The results are shown in Fig. 2.

The first part of the previous graph has been drawn with an extended scale for frequency. Superimposed on it are the individual results for three experiments in which 'Dibenamine' had been given to the animal. The output at 10 pulses per sec. is increased some sevenfold and now equals the maximum output in the untreated animal. Furthermore the difference in output with frequency in this range has disappeared.

We suggest that the explanation of these observations is that the sympathin release per nerve volley is constant, and that the fraction utilized by the tissues is greater at the lower frequencies of stimulation.

Autoradiography of End-plates with Carbon-14 – Calabash – Curarine I and Carbon-14 – Decamethonium

A HUNDRED years have passed since Claude Bernard's publication of his investigations on the action of curarine in "Leçons sur les effets des substances toxiques et médicamenteuses"[1]. He was able by indirect experiments to localize the curare-block in the end-plates of skeletal muscle. Some time ago when we investigated the metabolism of carbon-14 – curarine I in the cat[2], we tried to obtain autoradiographs of muscle, intending to show the fixation of this alkaloid directly at the neuro-muscular junctions.

For this purpose we had to synthesize carbon-14 – curarine of the highest possible radioactivity by methylation of 2·0 mgm. nor-curarine with an excess of 6·4 mgm. $^{14}CH_3I$, having the activity of 1 mc. After recrystallization we obtained 0·25 mgm. pure carbon-14 – curarine – iodide (biquaternary) with an activity of 24·2 μc./mgm. The minimal lethal dose of the water solution was injected into the veins of the tails of mice, which died of asphyxia within 40–120 sec. The diaphragms of these animals were stretched over steel rings of the same diameter (22 mm.) and dried in air. They were then brought into contact with X-ray film (Ilford X-ray PM_1) or mounted on microscope slides and covered by stripping film (Kodak). After developing the films the end-plates were stained by the Koelle method, in which acetylthiocholine is split by the cholinesterase, brown copper sulphide finally resulting[3].

After 60 days the resulting pictures on X-ray film showed a slight blackening in the region of the end-plates, which lie in a band of 260μ thickness around the centrum tendineum. In addition, there was blackening over the centrally situated vessels due to radioactivity in the blood. On microscopic examination of the stripping film a diffuse formation of silver grains over the end-plates was seen; but the crossfire over this region had been so heavy that only twice the grain density existed over each end-plate as compared to its immediate surroundings. The whole region had a 4–6 times higher density of grains compared with a corresponding region of muscle without end-plates.

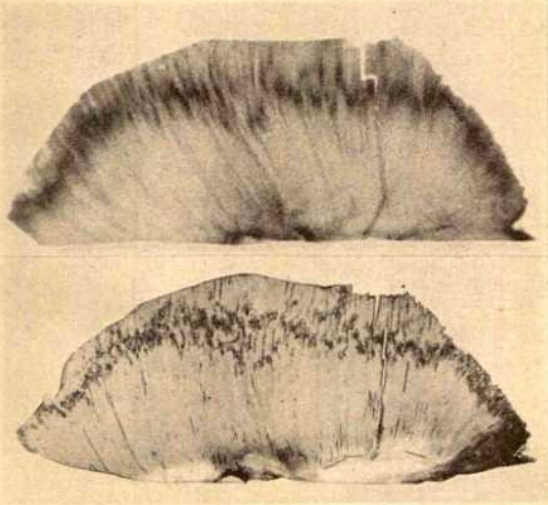

Fig. 1. Autoradiography of mouse diaphragm with carbon-14–decamethonium in comparison with staining of end-plates in the same diaphragm by the Koelle method (× c. 4)

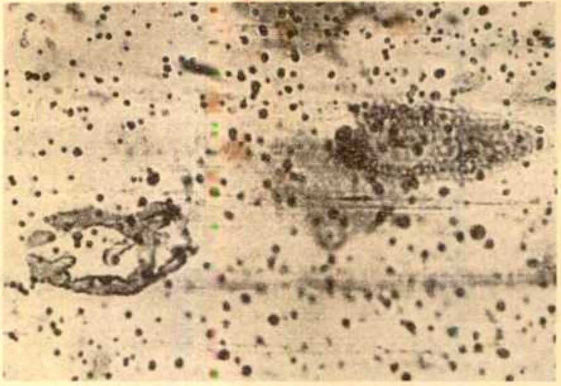

Fig. 2. Stained end-plates (Koelle method, × c. 700) and silver grains in stripping film by carbon-14–decamethonium

In order to obtain a much higher specific activity in a curarizing molecule we then methylated decamethylendiamine with $^{14}CH_3I$ and obtained 0·44 mgm. decamethonium with six carbon-14 atoms. The specific radioactivity was approximately five times larger than that of carbon-14 – curarine. After five days the resulting autoradiographs again showed clearly the localization over the end-plates, especially when compared with the stained diaphragms (Fig. 1). Over this region we counted four times more silver grains in the unit area of stripping film than in the muscle layer farther out (Fig. 2).

These pictures thus prove the fixation of 'curarizing' and 'depolarizing' drugs in the end-plate. They make possible the calculation of the number of molecules reacting with the receptor surface. We found 8 × 10^6 curarine molecules bound to one end-plate and 1·7 × 10^{12} molecules/cm.^{2} of apparent area of end-plate membrane, thus neglecting the possibility of a large increase in surface due to the palisade structure described by Couteaux[4]. The order of magnitude of apparent coverage of the end-plate surface is 5 per cent.

Details will be published in *Archives internationales de Pharmacodynamie et de Thérapie*.

Globulins in the Chicken Egg-White

LONGSWORTH *et al.*[1] demonstrated, by electrophoresis in the Tiselius apparatus, three globulins in the white of an egg. These were labelled G_1, G_2, G_3. (G_1 was identified later with the lysozyme.)

The antigenic properties of egg-globulins were demonstrated first by Hektoen and Cole[2] and later by me[3].

In my studies on egg-white and its constituents[3-5], I have employed the methods which permit the analysis of complex mixtures, such as electrophoresis and immunochemical techniques in agar gel. Thus, for the demonstration and enumeration of egg-globulins, four methods were used: (1) zone electrophoresis on paper and in agar gel[6]; immunological techniques (in this communication we give only the qualitative ones); (2) specific precipitation by double diffusion in agar plates[3–5] and (3) immunoelectrophoresis[7]; and (4) ultracentrifugation.

In this work, I have always studied comparatively the entire egg-white and its fractions, prepared chiefly by salting out with ammonium sulphate between 25 and 50 per cent of saturation. These fractions were substantially enriched in globulins (about 75 per cent as determined by electrophoresis in the Tiselius apparatus); but they still contain variable amounts of egg albumin, conalbumin, ovomucoid and lysozyme.

In immunological experiments I employed two sorts of antisera: anti-egg-white and anti-egg-globulin preparations (fractions precipitated by ammonium sulphate at 50 per cent saturation). The latter reacts more strongly, quantitatively and qualitatively, than the former, with the globulins of egg-white[4,5].

The results obtained with different techniques are as follows:

By electrophoresis on filter-paper (barbiturate buffer μ 0·1, pH 8·2, 6 hr., 4 V./cm.) stained with bromphenol blue, the 'true' globulins are separated from the lysozyme. The latter forms an indefinite trail near the negative end of the paper strip. The egg-globulins give one intensively stained spot, situated between those of egg albumin and conalbumin. The total egg-white and the fractions poor in egg globulins give a faint spot at the same place; the analysis of the 'incomplete egg-white' (artificial preparation, deprived of globulins[3–5]) shows no colour in this position.

By electrophoresis in agar gel (barbiturate buffer, μ 0·05, pH 8·2, 5 hr., 4 V./cm.) a larger number of constituents is demonstrated, especially when stained with the 'Amidoschwartz' (black-blue naphthol B 'Geigy'). It is interesting to note that the natural egg-white does not give the same egg globulin spot as the fractionated preparations[5]. Thus, independent of the total protein concentration, the total egg-white analysis revealed only the spot which I have labelled β_2, while my globulin preparations never give this spot, but form the spots β_1 and β_3[6]. Other visible globulin spots are α_1 and α_2; the last correspond to constituents which do not migrate from the original reservoir and the 'tongue' due to lysozyme (an artefact caused by retention of lysozyme near the original reservoir by the agar[4]).

The other dyes employed react differently with the various globulins. For example, azocarmin reacts strongly with the β_1 but very weakly with the β_3. These facts suggest that the available terminal groupings of these two constituents are not the same.

Sudan black did not colour any of the globulins, indicating that they are not lipoproteins.

By specific precipitation by double diffusion in agar plates using the procedure described by me[4,5], numerous lines can be seen, which I attribute to the precipitating systems of egg globulins and their homologous antibodies. There are two kinds of lines: when the concentrations of the antibody and the antigen are near the point of equivalence or an excess of antigen, the first lines appear in 2–3 days near the serum reservoir; the second appears more slowly (6–10 days) and are always near the antigen reservoir. These two kinds of lines correspond to antigens with different diffusion constants, respectively high and low. I have observed one line of the first kind and up to five lines of the second kind. The first line is not apparent with anti-egg-white serum[5].

Table 1

Technique	No. of egg-globulins demonstrated in: Total egg-white	Preparations of egg globulin
Electrophoresis (Tiselius)	2 [1] ($G_2 + G_3$)	2
Zone electrophoresis:		
(*a*) Paper	1 [3]	1
(*b*) Agar gel	2 [5] (α_2, β_2)	4 [6] (α_1, α_2, β_1, β_3)
Specific precipitation	1 [2]	1 [2]
Specific precipitation in agar plates	4–5 [4,5]	6 [4,5]
Immunoelectrophoresis	3–4 [5]	9 [5]

N.B.—The lysozyme has not been included in this table.

By immunoelectrophoresis, the number of constituents is also dependent on the nature of the serum. Thus, with anti-egg-white serum, the line of β_3-globulin is absent, while it is the principal globulin line with anti-egg-globulin serum.

The number of globulin lines varies with the nature of the fraction studied, but the total number of different lines is at least nine.

The corresponding constituents are classified according to their mobility. I enumerated three α_2 (one of which corresponds to lysozyme), three β_1, two β_2 and one β_3. The lines of α_2 and β_1 are always formed near the antigen reservoir while that of β_3 corresponds to a protein of high diffusion constant.

Sedimentation studies have demonstrated that in my fractions there are constituents of high sedimentation constant ($S_{20} = 15$ and 18).

In conclusion, at east nine globulins have been demonstrated in the chicken egg-white by immunoelectrophoresis; but it is possible that there are more which might be demonstrated with different sera or methods.

Coagulase Activity *in vivo*

COAGULASE production is a property of all pathogenic *Staphylococci* and is the most commonly accepted single criterion of pathogenicity. In addition it has been shown that coagulase plays a part in staphylococcal infections. Evidence for this is indirect: first, clottable plasma inhibits phagocytosis of *Staphylococci*[1]; secondly, rabbits can be protected from *Staph. aureus* infection by human coagulase-inhibiting serum[2], and, also, they receive a degree of immunity against such infection by active immunization with coagulase[3].

To our knowledge, however, there is no experimental evidence that coagulase does in fact exercise its clotting action *in vivo* except that in rabbits Tager[4] mentions the occasional fall in blood fibrinogen and death following the intravenous injection of very large doses of coagulase.

The present report presents what is considered to be evidence of *in vivo* clotting by coagulase. The preparation used was a purified coagulase supplied by Dr. E. S. Duthie; this preparation, at a dilution of 1 in 500,000, clotted an equal volume of 1 in 5 human plasma in 1 hr. and no alpha toxin was detected. Chinchilla rabbits (approximately 2 kgm.) were slowly injected intravenously (10–15 min.) with 2–10 mgm. coagulase in 6–8 ml. normal saline. The coagulase effect *in vivo* was assessed in two ways: by the estimation of fibrinogen-levels and histologically.

Fibrinogen was estimated both chemically and electrophoretically. Doses of 2–5 mgm. of coagulase produced a precipitous drop in the fibrinogen-level, the drop being roughly proportional to the amount of coagulase introduced, and the fibrinogen-level at 30 min. after injection ranged from 15 to 40 per cent of the original value. Blood shed at this stage failed to clot and puncture wounds bled freely. The fibrinogen was rapidly re-formed and by the second or third day was twice the initial value or more. Thereafter the level slowly dropped and had returned to the original level at the end of a week. A drop in all globulin fractions was observed simultaneously with the fall in fibrinogen.

Injection of large doses of coagulase (10 mgm.) led to the death of the animals in 10–20 min. Microscopic examination of the organs showed widespread intravascular deposits which gave the staining reactions of fibrin. These deposits were formed of multiple fibrin strands lying parallel to one another and to the long axis of the vessel in which they lay. The deposits were present in small or moderate numbers in the liver, kidneys and adrenals and they were exceedingly numerous in the lung, where they occluded the majority of capillaries and many of the small and large arteries. These findings and the manner in which the animals died suggested that death was due to blockage of the pulmonary vasculature.

The microscopic findings and changes in fibrinogen-level are similar to those observed after the intravenous injection in animals of thrombin or thromboplastin, and in some cases of accidental hæmorrhage in pregnancy.

In control experiments, autoclaved coagulase was used: no fall in fibrinogen-level was observed. Full details of these experiments will be published later.

It appears from these experiments that coagulase, admittedly in high doses, has a potent action *in vivo*. Since purified, but not pure, coagulase was used, it cannot be entirely ruled out that accompanying impurities may be responsible for the changes described above. However, since coagulase is a clotting agent, it seems logical to assume that the disappearance of fibrinogen from the blood and the formation of fibrin deposits in the vessels are due to the action of coagulase itself.

We wish to thank Dr. E. S. Duthie for the generous supply of purified coagulase and Dr. E. B. Hendry and his staff for fibrinogen estimations.

Anaerobic Uptake of Glucose *in vitro* by the Isolated Rat Diaphragm

THE uptake of glucose *in vitro* by the isolated rat diaphragm has been reported to be the same under both aerobic and anaerobic conditions[1,2]. In these experiments the medium used for incubation was a balanced salt solution buffered with phosphate, and phosphate buffers are known to be inadequate for tissues exhibiting a high rate of glycolysis[3]. The uptake of glucose *in vitro* by the isolated rat diaphragm under aerobic and anaerobic conditions has therefore been re-investigated using as supporting medium a balanced salt solution buffered with bicarbonate.

The diaphragms were obtained from normal, hypophysectomized or adrenalectomized male albino Wistar rats of 100–150 gm. Normal animals were fasted for 20–24 hr. before use, and hypophysectomized or adrenalectomized animals were fasted for 6 hr. After excision the diaphragms were bisected along the central tendon and one half-diaphragm from each animal was prepared and incubated anaerobically, and the other prepared and incubated aerobically. The incubation media used were Geys' bicarbonate-buffered medium[4] and Krebs–Ringer phosphate solution (phosphate-buffered medium)[5]. (The Krebs–Ringer phosphate solution was modified by reducing the calcium content to approximately one-half. The calcium contents of the modified Krebs–Ringer phosphate and Geys' bicarbonate medium were then identical.) The bicarbonate-buffered medium was gassed either with 95 per cent nitrogen, 5 per cent carbon dioxide (anaerobic preparation and incubation) or 95 per cent oxygen, 5 per cent carbon dioxide (aerobic preparation and incubation). Phosphate-buffered medium was gassed either with nitrogen or oxygen. The glucose concentration of the medium was 2·5 mgm./ml. in all instances.

After excision the hemidiaphragms were washed for five minutes in the appropriate medium. The hemidiaphragms were then lightly blotted, transferred to small conical flasks containing 1 ml. of medium, the flasks gassed and sealed, and incubated for 1 hr. at 37° C. in a Dubnoff shaker. After incubation the hemidiaphragms were blotted and weighed and the residual glucose in the medium determined colorimetrically by Somogyi's modification of Nelson's method[6]. In some experiments the residual glucose was additionally determined manometrically using glucose oxidase, after the method of Keilin and Hartree[7]. Uptake of glucose by diaphragm was calculated as mgm. glucose disappearing

Table 1. Uptake of Glucose *in vitro* by the Isolated Rat Diaphragm under Aerobic and Anaerobic Conditions in Media buffered with Bicarbonate or Phosphate

State of rat	Incubation medium	Glucose uptake. Mean ± S.E. of mean (mgm. glucose/gm. of wet diaphragm/hr. of incubation)				
		Anaerobic	Aerobic	Difference (anaerobic–aerobic)	*t*	*P*
Intact	Bicarbonate-buffered medium	5·68 ± 0·11 (23)	3·03 ± 0·13 (23)	2·65 ± 0·17	15·6	< 0·001
Hypophysectomized		4·96 ± 0·22 (19)	3·54 ± 0·14 (19)	1·42 ± 0·25	5·61	< 0·001
Adrenalectomized		4·52 ± 0·25 (5)	3·04 ± 0·33 (5)	1·48 ± 0·41	3·70	< 0·01 > 0 001
Intact	Phosphate-buffered medium	3·23 ± 0·22 (12)	3·00 ± 0·22 (12)	0·23 ± 0·31	—	—

Figures in parentheses are number of observations from which the mean is derived.

Table 2. Comparison of Glucose Uptakes based on Glucose Values obtained by Copper Reduction (Somogyi, ref. 6) and by Glucose Oxidase (Keilin and Hartree, ref. 7)

Experiment No.	Glucose uptake (mgm. glucose/gm. of wet diaphragm/hr. of incubation)					
	Anaerobic		Aerobic		Difference (anaerobic–aerobic)	
	Copper reduction	Glucose oxidase	Copper reduction	Glucose oxidase	Copper reduction	Glucose oxidase
1	4·15	4·72	2·24	2·87	1·91	1·59
	4·85	5·53	3·26	3·80	1·85	1·53
2	4·38	5·82	1·92	3·36	2·46	2·46
	5·64	6·42	2·38	2·74	3·26	3·68

Each value represents the combined uptake of glucose by five hemidiaphragms incubated together in 3 ml. of bicarbonate-buffered medium.

from the medium/gm. of wet diaphragm/hour of incubation.

The uptake of glucose by the isolated rat diaphragm incubated in bicarbonate-buffered medium was found to be substantially greater under anaerobic conditions than under aerobic conditions (Table 1). The increase in glucose uptake under anaerobic conditions which was seen with diaphragms from normal, hypophysectomized or adrenalectomized rats was highly significant. Since this difference had not been reported by other workers who have studied the uptake of glucose by the isolated rat diaphragm under anaerobic conditions in phosphate-buffered media[1,2] the studies were repeated with a phosphate-buffered medium. In the phosphate-buffered medium the uptakes of glucose under aerobic and anaerobic conditions did not differ significantly—an observation in agreement with those of earlier studies by other workers[1,2], and in clear contrast to the results obtained in a bicarbonate-buffered medium. Measurements of *p*H before and after incubation showed that the *p*H of phosphate-buffered medium fell markedly during incubation under anaerobic conditions (*c.* 0·6 unit) whereas the *p*H of bicarbonate-buffered medium suffered little change (*c.* 0·1 unit).

Anaerobic incubation in a bicarbonate-buffered medium was associated with a significant fall in the level of glycogen in the diaphragm despite the high rate of glucose uptake, whereas aerobic incubation was associated with a significant increase in the level of glycogen. Lactic acid production was significantly increased under anaerobic conditions. Similar changes in the level of glycogen in diaphragm and of production of lactic acid by diaphragm have been noted previously, in phosphate-buffered medium, by Walaas and Walaas[1].

Chain, Catamzaro, Chain, Masi, Pocchiari and Rossi[8] have suggested that reducing substances other than glucose may be added to the medium by diaphragm during incubation and so lead to false values for uptake of glucose when glucose is estimated in the medium by methods based on reduction. In two experiments, therefore, glucose was estimated in the medium both by the copper reduction method of Somogyi[6] and by means of the specific glucose oxidase[7]. The uptakes of glucose, based on glucose values obtained with glucose oxidase, were higher than those obtained by the Somogyi method of glucose estimation. This observation would be in keeping with the suggestion of Chain *et al.* The increase in glucose uptake under anaerobic conditions in the bicarbonate-buffered medium was, however, still evident when glucose uptakes were calculated from glucose values obtained by the glucose oxidase method (Table 2).

These studies indicate that the uptake of glucose by the isolated rat diaphragm is increased under anaerobic conditions in a medium buffered with bicarbonate. The significance of these results in relation to the mode of uptake of glucose by the isolated rat diaphragm will not be discussed here. In a phosphate-buffered medium, anaerobic incubation does not lead to any alteration in the uptake of glucose by the isolated rat diaphragm. Media buffered with phosphate would appear to be unsuitable for *in vitro* studies with the isolated rat diaphragm, because of their poor buffering power. Estimations of glucose by both copper reduction (Somogyi) and by glucose oxidase have supported the suggestion of Chain *et al.*[8] that reducing substances other than glucose are added to the medium during incubation of the isolated rat diaphragm and that these are estimated together with glucose when copper reduction methods are used.

I wish to thank Prof. F. G. Young for helpful advice and criticism; Miss N. Savage for the gift of a preparation of glucose oxidase; and Mrs. J. C. D. Coe for technical assistance. The cost of this work was largely defrayed by a grant from the Medical Research Council.

Heat Changes during the Clotting of Fibrinogen

In order to get a better insight into the energetics of the clotting of fibrinogen, we conducted heat measurements using the Benzinger[1,2] microcalorimeter.

The heat change during clotting of fibrinogen comes essentially from three sources: (1) the splitting of peptide bonds by thrombin, (2) the neutralization by the buffer system of the charged groups created, and (3) polymerization of the fibrin molecules to a network.

The polymerization involves the formation of 19 hydrogen bonds[3] where the histidine groups appear to be the acceptors[4,5]. In order that the histidines may serve as acceptors at pH 6, protons have to be removed. According to Mihalyi[4], at pH 6 three protons are removed from histidine residues.

In these experiments bovine fibrinogen, purified according to the method of Laki[6], and Parke–Davis thrombin were used. Usually, the thrombin solution and the fibrinogen solution were dialysed against the same buffer salt solution. About 5 mgm. fibrinogen per ml. was suitable for the measurements. Thrombin was added in an amount sufficient to make the clotting complete in 20–25 min. The experiments were performed in phosphate, tris (hydroxymethyl) amino methane (*tris*) and borate buffers. The results of the experiments are summarized in Fig. 1.

It is seen that in phosphate and borate buffers the heat evolved amounts to about 44 kcal. in a fairly wide pH range. In *tris* buffer the heat evolved is higher.

The 44 kcal. of heat evolution found in phosphate buffer at pH 7 is practically the same as found by Sturtevant *et al.*[3] for the heat of the polymerization reaction only. From this it follows that the heat of the splitting which is included in our experiments is very small and thus negligible.

At lower pH's Mihalyi finds that, as a result of the polymerizations, protons appear to originate from the histidine residues. This process absorbs about 6–7 kcal. of heat per proton. At pH 6, where three protons (per mole of fibrinogen, mol.wt. = 330,000) appear, this heat absorption is about 20 kcal. This means that at this pH instead of 44 kcal. we would measure 20 kcal. less in the polymerization reaction.

In the total reaction this heat absorption will be compensated by the neutralization heat of the amino-groups generated by the removal of the peptides. In phosphate buffer, therefore, we obtain a line which runs from pH 8·5 to 6 at a level of approximately 44 kcal. (Fig. 1).

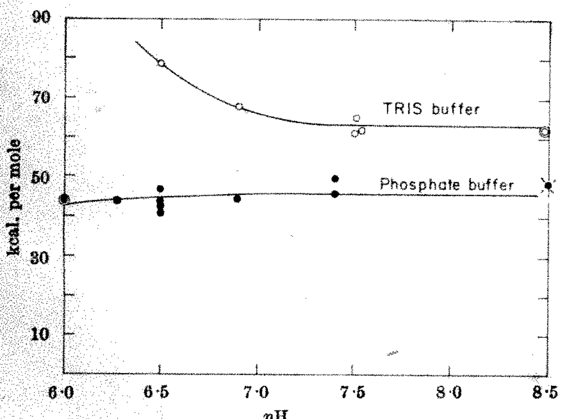

Fig. 1. The heat (in kcal.) liberated during clotting the fibrinogen plotted against pH of various buffers at which the clotting was performed. ●, Phosphate buffer; ○, *tris* buffer; ×, borate buffer

In *tris* buffer the situation is different so far as the neutralization of the liberated charged groups is concerned. From pH 8 down to pH 6 we find that the heat of neutralization of the two carboxyl groups is uniformly about 20 kcal., since *tris* involves about 11 kcal.[2,7] for the neutralization of a proton. The polymerization heat again can be expected to be 44 kcal.; but now as we approach pH 6, the three protons removed from the histidine residues are neutralized by the buffer, which involves considerable heat (in contrast to phosphate buffer[2,7]), thus overcompensating the heat consumption needed to remove these protons. We expect the curve, therefore, to bend upward, but to run about 20 kcal. higher (between pH 7–8·5) than the results obtained in phosphate buffer. The 20 kcal. difference is the result of the neutralization of the two protons of the carboxyl groups which are liberated during the enzymatic phase.

These experiments definitely indicate, then, that two (but not more) peptide groups are split during the clotting of fibrinogen. It is expected, therefore, that the peptides split from fibrinogen should contain C-terminal groups. This is in agreement with recent experiments of Gladner and Laki (unpublished work) showing that carboxypeptidase brings about a considerable degradation of both of these peptides. A detailed account of the work will be submitted for publication elsewhere.

Cell Membranes and Morphogenesis

Cell membranes can be readily visualized in the electron microscope; but a rather special cell system is needed if one wishes to study their supposed role[1,2] in morphogenesis. In the hair follicle we have been able to examine at high resolution a system which fulfils most of the electron microscopist's demands. It is small enough not to make the task of surveying it at high magnification too formidable and, in a geometrical sense, simple, in that the differentiating cells move away from the papilla in almost linear streams, preserving the order of their formation.

In normal growth a steady stream of cells, maintained by division in the neighbourhood of the papilla at the base of the follicle, passes up the tube formed by the outer root sheath and differentiates to form as many as six concentric cylinders; the three outer cylinders constitute the inner root sheath and the three central, the hair proper. The cells of these layers are differentiated in their shape and in the different intracellular materials which they make.

In the mid bulb immediately above the zone of cell division the plasma membrane, seen in material fixed in osmium tetroxide solution and embedded by standard electron microscopical procedures, consists of a single thin (<50 A.) dense line bounding the cytoplasm. The cell surfaces are extremely convoluted and long finger-like pseudopods may penetrate far into neighbouring cells. These fixed appearances probably record momentary aspects of the restless membrane activity often noted in films of cultured cells. One gains the impression that adhesion between cells is slight. The intercellular space often dilates into wide empty openings (up to 2–3μ wide); where the membranes are closer it is evident (Fig. 1) that the gap is actually filled by a material of lower electron absorption than that of the membranes. Over certain small areas the separation is more constant (125–150 A.), and these seem to correspond to areas of true adhesion with the intercellular material acting as a cement. Such localized contacts also characterize the epidermis[3,4] and outer root sheath.

The first signs of differentiation appear in the presumptive cuticle cells and are shown by a spread of the 'adhesive contacts' leading to a closing of the gaps, a smoothing out of the cell surfaces and the progressive assumption of a columnar habit by the cells. This development also occurs later and to a lesser degree in the sheath cells. In the cortex, however, contact areas remain small and local, membrane activity persists and the intercellular gaps afford pathways for melanocyte processes bearing pigment. The fully established contacts between the cuticle cells seem, however, to bar further peripheral penetration by the pigmented processes, and the cuticle and sheaths thus remain unpigmented.

At about the level of the tip of the papilla all the cells (except those of the cuticle) have begun the synthesis of their characteristic products: fibrils of keratin in the cortex and droplets of amorphous trichohyaline in the inner root sheath. Trichohyaline synthesis commences first and proceeds farthest in the Henle cells nearest the outer root sheath; it is delayed and less marked in the two inner layers of the sheath. In each of these three cell layers, and with a time-lag between each, the amorphous trichohyaline droplets suddenly transform into a birefringent fibrous modification, a change well shown electron microscopically, and at the same time the cell membranes separate to about 250–300 A. with the deposition between them of a dense central layer. This type of membrane modification occurs also in the cuticle cells and leads to the deposition of a most elaborate succession of coats between the cells (Fig. 2). Proceeding from one cell to the other (and counting the 'white' lines which represent material of low electron density) we have here certainly seven layers and perhaps even nine.

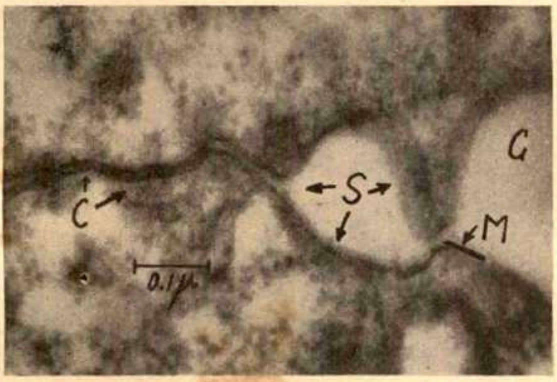

Fig. 1. Portions of two cells in the mid bulb of the hair follicle showing the nature of the areas of contact *C*. *G*, an intercellular gap; *S*, intercellular cement; *M*, the plasma membrane. (× 116,000)

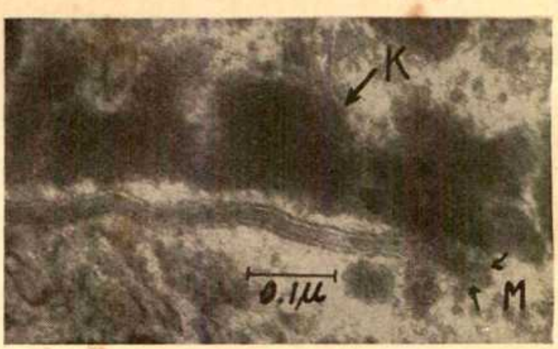

Fig. 2. Membrane complex developed between two cuticle cells at the level of keratin formation. *K*, keratin droplets; *M*, plasma membranes. (× 120,000)

In the central fibrous cortex of the hair the membranes, which have persisted in their surface activity longer than elsewhere, finally dilate and become cemented together as the cells fill with fibrous keratin, but do not develop a complex layered structure.

Surveying the whole process, it is seen that everywhere changes in cell contacts accompany differentiation. In the bulb localized adhesion, spread of contacts and suppression of membrane activity (contact inhibition[5]) seem early formative events in the causal chain; the later more elaborate development of the membranes seems part of the process of consolidating the tissue.

A New Method for the Identification of Biochemical Mutants of Micro-organisms

A RAPID method for the identification of biochemical mutants of *Ustilago maydis* has been devised. The method is suitable for sporing or non-mycelial micro-organisms which form discrete colonies on agar.

Thirty-six possible requirements for single growth-factors are tested. Twelve plates of minimal medium are each supplemented with different combinations of six growth-factors with the arrangement shown in Table 1. A mutant strain with a single biochemical requirement when inoculated on all twelve plates will grow on two of them, one of plates 1–6 and one of plates 7–12. Thirty-six combinations are possible ; each combination indicates a different requirement. The number of requirements tested can be varied by altering the number of plates and the arrangement of growth-factors among them.

Table 1

	Plates 1	2	3	4	5	6
Plates 7	adenine	biotin	phenylalanine	alanine	arginine	leucine
8	hypoxanthine	folic acid	serine	cysteine	ornithine	glycine
9	cytosine	pantothenic acid	tryptophan	threonine	aspartic acid	*iso*leucine
10	guanine	pyridoxin	tyrosine	thiosulphate	proline	histidine
11	thymine	thiamin	*p*-amino benzoic acid	methionine	glutamic acid	lysine
12	uracil	riboflavin	nicotinic acid	choline	inositol	valine

An inoculating instrument with twenty-five points is used for transferring cells from each of twenty-five different mutant colonies growing on complete agar medium to each of the twelve plates. The multiple inoculator consists of twenty-five bolts (½ in., 10 *BA*) fitted to double-thickness zinc gauze. A short handle allows the instrument to be sterilized by dipping in methylated spirit and flaming. In preparing the master plate of complete medium the mutants are inoculated in positions corresponding to the points of the inoculating instrument and then incubated until a suitable growth has occurred. The Lederbergs' technique of replicating colonies with velvet or damp filter paper would be an equally suitable method for carrying out the inoculations[1].

So far as possible the arrangement of growth-factors allows for the detection of likely double or alternative requirements. Mutants requiring, for example, both *iso*leucine and valine for growth will only grow on plate 6, and the precise requirement must be tested with different combinations of the six growth-factors in that plate. Mutants with alternative requirements will grow on more than two plates. For example, those using methionine or cysteine will grow on plates 4, 8 and 11, and their requirements can be detected at once.

When large numbers of mutants are to be identified, this technique is more efficient than previous methods in which the field of search is progressively reduced[2,3]. With one or a few mutants auxanographic techniques are preferable[4,5].

The Snail's Foot as a Langmuir Trough

THE importance of the surface film of protein on stationary or slowly moving bodies of water as a food for small aquatic animals had apparently not been realized until the recent work of Goldacre[1], who made film-pressure measurements on ponds, lakes and rivers and found on all of them unimolecular layers of protein in higher or lower states of compression. A concomitant study of the behaviour of small aquatic animals led him to the conclusion that they ate this protein in large amounts. Observations of the movements of dust particles in a film during its ingurgitation by a tadpole indicated that this animal might well eat its own dry weight of protein, spread as a monolayer at the air–water interface, in one day.

I have recently acquired, through the courtesy of Mr. G. Ashby of the Zoological Society of London, some water snails of the South American species *Pomacea canaliculata* Studies of the behaviour of these animals, of which my largest specimen weighs 52 gm., have shown that they not only eat surface films of protein, but also have the technique of compressing them to fibrous masses which are then eaten without a disproportionately high intake of water.

The phenomenon is manifested in the following manner. A snail in the usual resting position, adhering to the wall of the tank or to a floating plant just below the water surface, detaches the anterior portion of its foot and extends and curves it in such a manner as to form, either alone or with the tank wall, a funnel with its rim in the surface. Rapid undulatory movements are then seen to pass posteriorly from the periphery of the foot, while from the motion of particles in the adjacent water surface it is clear that the material constituting the surface film is being drawn towards the mouth of the funnel. Within a few seconds the presence of a collapsed protein film is evident at the water surface within the funnel. As the protein accumulates, the water-level is forced down and after, say 10 sec., the funnel is almost empty, with denatured protein tightly packed in the narrow end. After a short period of further accumulation, the animal brings its mouth forward and downward and eats the protein.

The funnel is not refilled from above during compression of the film since the foot is rendered hydrophobic by the protein and the contact angle between foot and water is hence increased. The protein is probably anchored to the mucin layer of the foot by its polar side-chains, the hydrophobic, non-polar groups being directed predominantly towards the air. The strongly anionic character of the mucin is shown by the avidity with which, *in situ*, it takes up basic dyes such as methylene blue.

This behaviour is very much more frequent in young snails than in adults. With the latter, film compression sometimes occurs, as it were, absent-mindedly, while the animal is engaged in a clearly more rewarding pursuit such as the consumption of a lettuce leaf. In such an event the protein mass is abandoned.

It may be pointed out that proteins are the only quantitatively important biological materials that yield surface films capable of pedipulation in the fashion here manifested.

Influence of Freezing-rate on the Denaturation of Cold-stored Fish

It is commonly held that the major factor governing the changes which gradually take place in frozen muscle is the temperature of storage, and that the speed at which the tissue was originally frozen is of relatively small importance. Though storage temperature is undoubtedly the biggest single factor, it now appears that freezing-rate is more important than was formerly supposed.

Examination of published work relating to the effect of freezing-rate on fish after cold storage shows that in most cases this rate is very arbitrarily defined. At the worst, the only information given is the temperature of the medium in which material to be frozen is placed. A better concept is the 'freezing-time' defined as the time taken for a certain part of the muscle to pass through two fixed temperatures as measured by thermocouples. However, the tendency is still to relate observations to a simple numerical value, without intimate knowledge of corresponding disposition of the ice crystals or any cell damage for which they may be responsible.

It was the aim of the present work to investigate denaturation in relation to the disposition of the ice in fillets of North Sea cod (*Gadus callarias*). The type of ice distribution was indicated indirectly by a recent technique, which utilizes the amount of deoxyribose nucleic acid in the intercellular fluid as a measure of the amount of cell damage[1,2]. Denaturation was assessed from the percentage of muscle proteins that would dissolve in neutral 5 per cent sodium chloride. The reproducibility and accuracy of this method was much enhanced by taking account of most of the biological variation which normally destroys much of its usefulness. The technique by which this was done has recently been described[3]. Fillets were frozen at different speeds by stacking them in vertical piles on an aluminium plate maintained at —78° C. by solid carbon dioxide. It had previously been found[4] that such an arrangement yielded fillets frozen over a suitable range of conditions, those in contact with the plate freezing most quickly, and those at the top of the stack most slowly. Observations at the time of writing have been limited to fillets afterwards stored at —14° C. for 86, 108, 148 and 162 days, and at —30° C. for 328 and 390 days.

While the overall extent of denaturation depended on the length of storage, the results showed clearly that large differences in denaturation existed between fish frozen at different rates. Denaturation was relatively low where high-speed freezing produced small intracellular ice columns. It increased steadily with slower freezing to a maximum value at the point where the largest possible intracellular ice columns were produced, the proteins being then compressed into narrow strips along the margins of the cells (*see* Love[1], picture *E*). As freezing became slower still, cells were burst open, denaturation decreased, and decreased still more when the ice commenced to form in the intercellular spaces, until at freezing-times of 200–250 min. (time to cool from 0° to —5° C.), where all ice was intercellular and fibres no longer ruptured, denaturation was at a minimum. There was a gradual increase in denaturation after very slow freezing (500 min. and upwards), probably the result of dehydration, the ice front moving so slowly that osmosis was occurring from the cells outwards. An important factor affecting denaturation seems, therefore, to be the mode of ice formation and distribution and the resulting concentration patterns of tissue salts, rather than actual mechanical damage to the cell walls.

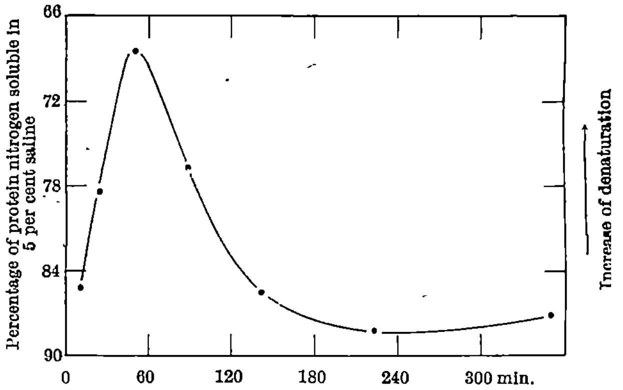

Fig. 1. Percentage of cod muscle proteins which can be dissolved in 5 per cent sodium chloride after freezing fillets at different rates and storing them at —30° C. for 390 days

The results from storage at —30° C. for 390 days are shown in Fig. 1, which illustrates the considerable difference in denaturation between fish frozen in 70 and 220 minutes. By deoxyribonucleic acid measurements the change-over from intra- to intercellular freezing was shown to have commenced in fillets with a freezing time of 60 min. and to have been complete in those of 130 min. freezing time in this experiment. The smoothness of the curve underlines the accuracy of the denaturation measurements. This pattern was not shown by fillets that had been stored at —14° C. for 162 days, since denaturation was almost complete at all rates of freezing. It is significant that the quantity of expressible fluid obtained under standard conditions from these fillets was almost the same at each rate of freezing, suggesting that the usefulness of such determinations is limited.

An indication of relative toughness can be obtained from a taste panel, and preliminary data obtained in this way suggest that the relation between toughness and denaturation is not a simple one, at any rate at low storage temperatures. For example, in Fig. 1, at a freezing-time of 220 min., 88·2 per cent of the proteins are soluble—a value but little below that of fresh fish (95–96 per cent)—but the muscle is undoubtedly tough to eat. This finding is in accord with the work of van Mameren[5], who detected no reduction in protein solubility at this temperature, in spite of increased toughness. Toughness and solubility appear to be more closely related at about —10° C.[5,6].

It would appear that these phenomena have previously been overlooked on account of the relatively narrow range of conditions under which they occur.

A full account of the completed work will be published elsewhere.

Protein solubilities were determined by Mr. J. I. M. Ironside and Mr. I. Robertson. Nucleic acids were determined by Miss Eleanor Brown. The work described in this communication is part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

Protective Action of Vitamin B_{12} in Experimental Liver Injury

THERE are several reports concerning the biochemical changes accompanying experimental liver damage by administration of carbon tetrachloride and other steatogenic poisons. However, the fundamental metabolic deviation causing fatty degeneration has not been well understood. Patwardhan *et al.*[1] have demonstrated that marked changes in the distribution and quantity of several constituents of the liver cells occur before structural damage to the organ. In the present communication, it is shown that a rapid rate of depletion of soluble sulphydryl compounds is among the major derangements in liver injury by carbon tetrachloride. The possibility has been indicated that the protection afforded by prior administration of vitamin B_{12} may be due to its known influence on sulphydryl metabolism[2].

Adult male rats (Wistar strain), 100–150 gm. in weight, reared on the laboratory stock diet, were given, intraperitoneally, vitamin B_{12} (10 μgm./animal) 3 hr. prior to carbon tetrachloride administration (2 c.c. per kgm. body-weight). It was ascertained from preliminary experiments that protection by the vitamin was best under these conditions and that animals not receiving the vitamin showed maximum liver fat accumulation at the end of about 48 hr., after which there was regeneration. Animals were killed at intervals after carbon tetrachloride injection and the livers quickly excised, chilled and homogenized in cold isotonic sucrose to a 20 per cent suspension. Determinations were made on aliquots of the whole liver and on centrifugally separated fractions. The values reported (Table 1) are averages for four animals from each group and are for the whole liver only, sampled at the end of 6 and 48 hr. after carbon tetrachloride poisoning and employing the analytical procedures cited.

It is seen that liver fat accumulation proceeds even after restoration of glutathione to normal levels and that vitamin B_{12} protects against rapid depletion of glutathione. A study of the distribution of glutathione in cell fractions has shown that while the mitochondrial fraction is completely devoid of it, nearly 80 per cent is present in the supernatant, the remainder being accounted for in the nuclei. Nuclear bound glutathione does not become depleted as a result of carbon tetrachloride injury. Mitochondrial damage in carbon tetrachloride injury can be inferred from alterations in pyridino-protein nucleotides[8] and lability of other acid-soluble nucleotides[9].

The protective action of vitamin B_{12} is more marked with respect to changes in ribonucleic acid and in phospholipids than in neutral lipids. It has apparently no effect on glycogen losses in the prenecrotic and necrotic stages. Deoxyribonucleic acid and methionine values remain unchanged throughout.

Lability of Intramitochondrial Components in Experimental Liver Injury

THE mitochondrial membrane has a limited ability to retain nucleotides and other co-factors like Mg^{++} which are essential for maintaining normal respiration and efficient coupled phosphorylation[1]. Exposure to hypotonic conditions, ageing, other environmental alterations and physiological states cause swelling of the mitochondria accompanied by biochemical modi-

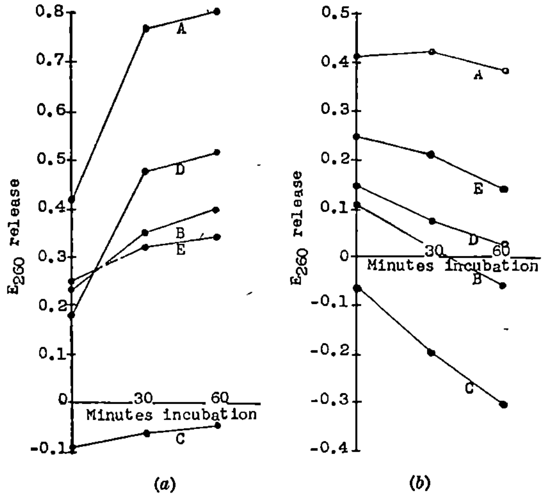

Fig. 1. (*a*) Release of acid-soluble nucleotides from mitochondria incubated in phosphate buffer; (*b*) effect of oxidative phosphorylation on E_{260} release.
A, Normal mitochondria; *B*, mitochondria from livers 6 hr. after injury by carbon tetrachloride; *C*, mitochondria from livers 48 hr. after injury by carbon tetrachloride; *D*, as in *B*, vitamin B_{12}-protected; *E*, as in *C*, vitamin B_{12}-protected

fications, such as loss of Mg^{++} and of acid-soluble nucleotides with absorption maximum at 260 mμ, increase in adenosine triphosphatase activity and dissociation of phosphorylation from oxidation[1-3]. Conditions favourable to oxidative phosphorylation or the presence of adenosine monophosphate apparently protect the mitochondria against this damage[1,4].

Uncoupling of oxidative phosphorylation has been reported in thyrotoxicosis[5], dietary necrotic liver degeneration[6] and experimental liver injury[2]. Mitochondrial preparations from such liver tissues show lowered oxygen consumption and decreased levels of pyridine nucleotides[2,5]. It was of interest to study their behaviour with respect to release of nucleotides and to ascertain the influence of prior administration of vitamin B_{12}, which protects against thyrotoxicosis[7] and injury by carbon tetrachloride[8]. This report relates to observations with the steatotic poison.

Well-fed adult rats (Wistar strain), 150–200 gm. in weight, were used for the different groups (Figs. 1*a* and *b*). Carbon tetrachloride was administered intraperitoneally at 2 ml. per kgm. body-weight, and control animals were similarly given corresponding amounts of distilled water. Vitamin B_{12} was also given intraperitoneally at 10 μgm. per animal, 3 hr. before carbon tetrachloride injection. The animals were killed by decapitation, 6 and 48 hr. after injury by carbon tetrachloride[8]. Mitochondria from the livers were prepared by the procedure of Schneider and Hogeboom[9]. The mitochondrial pellet was taken up in cold isotonic sucrose and aliquots equivalent to 500 mgm. wet weight of liver were incubated in the presence of 0·01 *M* phosphate buffer, *p*H 7·2, either alone or, to maintain conditions for oxidative phosphorylation[1], with additions of 3 μmol. each of magnesium chloride and adenosine monophosphate and 30 μmol. of glutamate in a final volume of 4·0 ml.; powdered sucrose was added to give isotonic conditions. At commencement, as well as at the end of 30- and 60-min. intervals, the suspensions were spun at 7,500 × *g*. The supernatant was deproteinized with 2 ml. of 1·5 *N* perchloric acid and the optical density at 260 mμ of the resulting solution was read in a Beckman *DU* spectrophotometer (Figs. 1*a* and *b*). Results are averages of at least quadruplicate determinations in each group.

As may be expected, incubation of mitochondria from normal livers in phosphate buffer results in a loss of intramitochondrial nucleotides which is checked in the presence of the oxidizable substrate. In mitochondria from steatotic livers the initial release of E_{260} material is very low and points to damage to mitochondrial morphology *in vivo*. There is a non-specific interference from absorption due to Mg^{++} and PO_4''', the influence of which are apparently more pronounced with mitochondrial preparations from livers 48 hr. after administration of carbon tetrachloride.

The uptake of adenosine monophosphate from the medium in presence of glutamate could be due to the action of surface-adenylate kinase and is consistent with the suggestion[2] that steatotic poisons interfere with the mechanism whereby inorganic phosphate is transferred to adenosine diphosphate to form adenosine triphosphate coincident with oxidation rather than with adenylate kinase action.

The protective action of vitamin B_{12} against poisoning by carbon tetrachloride[8] is reflected in the initially higher release of E_{260} material of mitochondrial preparations, as well as in its more normal increased release with time to the surrounding medium. This protection may not be specific and could arise from the general lipotropic action of the vitamin and from its known influence on sulphydryl conservation and nucleotide metabolism.

Diphenylhydantoin and Brain-Levels of 5-Hydroxytryptamine

It has been demonstrated that the anti-epileptic drug, diphenylhydantoin ('Phenytoin'), in rats is capable of inhibiting the pituitary–adrenal system, preventing the usual depletion of adrenal ascorbic acid by such stresses as unilateral adrenalectomy, intravenous vasopressin and subcutaneous epinephrine[1].

There is evidence to suggest that 5-hydroxytryptamine might be an important neuroregulatory amine, perhaps playing a part in the transmission of impulses in the brain. It has been established that 5-hydroxytryptamine is present in certain areas of the brain[2,3], and that many of these regions are capable of synthesizing 5-hydroxytryptamine[4]. The hypothalamus, an area of extreme importance in autonomic and possibly hormonal homeostasis in the organism, is one region with high levels of 5-hydroxytryptamine and the enzyme responsible for its formation.

It seemed of some interest to determine the effect of diphenylhydantoin upon brain-levels of 5-hydroxytryptamine, since to date the only substances reported to alter brain-levels of 5-hydroxytryptamine have been, on one hand, the monoamine oxidase inhibitor, iproniazid[5], and the immediate precursor of 5-hydroxytryptamine, 5-hydroxytryptophan[6], which lead to an increase, and, on the other hand, reserpine, rescinnamine and 11-demethoxyreserpine, which lead to a decrease, in brain 5-hydroxytryptamine[7,8].

In preliminary experiments it was found that rats treated with diphenylhydantoin (100 mgm./kgm. B.I.D., intraperitoneally for two days) had twice the normal brain-level of 5-hydroxytryptamine (see Table 1). A further increase in the elevation occurred after the administration of 5-hydroxytryptophan (100 mgm./kgm. intraperitoneally given to diphenylhydantoin-treated rats). These animals were killed 1 hr. after receiving 5-hydroxytryptophan, and the adrenal ascorbic acid level was found to be lowered (no such result was obtained in control animals treated with the slightly alkaline medium in which 5-hydroxytryptophan was dissolved).

Table 1

Primary* treatment	Secondary treatment	Adrenal ascorbic acid† (μgm./100 mgm. adrenal)	5-Hydroxytryptamine† in brain, (mμgm./gm.)
None	None	460 (25)‡	330 (25)
Diphenylhydantoin	None	426 (12)	682 (6)
Diphenylhydantoin	One adrenal removed, and 1 hr. later the second taken for analysis	426 (10)	—
None	5-HTP 100 mgm./kgm. i.p. 1 hr. previously	—	879 (5)
Diphenylhydantoin	5-HTP 100 mgm./kgm. i.p 1 hr. previously	374 (9)	1,290 (6)
None	Reserpine 2·5 mgm./kgm s.c. 6 hr. previously	364 (5)	100 (3)
Diphenylhydantoin	Reserpine 2·5 mgm./kgm. s.c. 6 hr. previously	413 (2)	245 (2)

* In these experiments, male rats 150–225 gm. were used. The diphenylhydantoin was administered intraperitoneally 100 mgm./kgm. twice daily for four doses.

† Bioassay of 5-hydroxytryptamine was on hearts of *Venus mercenaria*: acetone extracts of whole brain (excluding cerebellum) made by procedure of Amin, Crawford and Gaddum (ref. 2). Ascorbic acid was determined by method of Roe and Kuether (ref. 9).

‡ Figures in parentheses indicate the number of rats.

Reserpine (2·5 mgm./kgm. subcutaneously) caused the same degree of depletion of brain 5-hydroxytryptamine in diphenylhydantoin-treated rats as in untreated animals when examined at 6 hr. after administering reserpine. However, there was no apparent depletion of adrenal ascorbic acid in the diphenylhydantoin-treated animals, in contrast to the regularly observed decrease seen in normal control animals. In control animals reserpine caused a more marked depletion of adrenal ascorbic acid at 2 and 4 hr., whereas in a small group of diphenylhydantoin-treated animals no significant changes were determined at these times.

Further examination of these interesting relationships are being undertaken; but it is clear that in the rat diphenylhydantoin causes an increase in the level of 5-hydroxytryptamine in the brain.

This investigation was supported, in part, by a grant from the Fluid Research Fund, Yale University, and a grant from the National Institutes of Health, Public Health Service.

Shikimic Acid in Apple Fruits

FOLLOWING the discovery of quinic acid in apple fruits[1] it has been found in other fruits[2,3] and in grass[4]. It was originally suggested that quinic acid might provide a link between aliphatic and aromatic metabolism in plants and that shikimic acid might be the first stage from quinic acid in the 'disaturation' of the six-membered carbon ring[1]. However, shikimic acid could not at that time be found in apples. It was, however, isolated later from grass[5] and has recently been detected in small amounts in the juice of cider apples by Phillips, Pollard and Whiting[6], who used paper chromatography and a specific colour reaction. The development of the technique of gradient elution of organic acids from anion exchange resins[7,8] has greatly facilitated the separation and isolation in the pure state of organic acids present in very small amount from solutions which also contain other acids in much larger quantity; by using this technique, an acid has now been found in very small amount on paper chromatograms prepared from extracts of the peel of Bramley's Seedling apples which gave a yellow to orange colour with Cartwright and Roberts reagent[9] (specific for quinic, shikimic and dihydroshikimic acids[6]) and corresponded in R_{Malic} values with shikimic acid. About 20 mgm. of this acid was obtained in the pure form from an extract of 300 gm. of the peel of the same apples using gradient elution (acetic acid) from 'Dowex 1' columns in the acetate form. The acid had a specific rotation of $[\alpha]_D^{20} = -177\cdot5^\circ$ (an authentic sample, measured at the same concentration, of shikimic acid kindly supplied by Dr. Wayne Umbreit of the Merck Institute, gave $[\alpha]_D^{20} = -177\cdot1^\circ$). The elementary analysis gave, C, 46·9; H, 5·8 per cent; calculated for shikimic acid C, 43·3; H, 5·79 per cent. The specimen had a melting point of 182·5° C. (corrected); mixed melting point with the Merck sample of shikimic acid, 183·5° C. (corrected). It was undoubtedly shikimic acid.

The acid is barely detectable in the peel of unripe apples; but it increases in amount as the fruit ripens and becomes senescent. The amount of shikimic acid in pulp tissue even from senescent fruit is extremely small. It is interesting that there is also much less quinic acid in the pulp than in the peel of comparable apples[10]. If quinic and shikimic acids are indeed concerned in a chain of reactions leading to full aromatization of the six-carbon ring, it is possible that the rate of conversion of shikimic acid to the next member of the sequence is greater than the rate of production of quinic acid, so that shikimic acid appears in detectable amounts only during the general slowing down of metabolic activity associated with the senescence of the fruit.

Physiological Control of Population Growth

Mouse ova collected from the Fallopian tubes at the eight-cell stage have been consistently shown to develop to blastulæ when cultivated in a purified medium[1]. It has now been observed that if progesterone is added to this medium, all ova die when the concentration is 8 μgm./ml. or more. A proportion survive at 4 μgm./ml., while a concentration of 2 μgm./ml. is without apparent effect. Since Forbes[2] found a level of 5·2 μgm./ml. in human plasma it seemed possible that this action of progesterone, together with those described by Pincus[3] and Ishikawa[4], might provide a method of fertility control. However, when recently inseminated mice were injected with 10 mgm. of progesterone intraperitoneally on two successive days, there was no reduction in the number of free blastulæ or of implantation sites.

The development of blastulæ from tubal ova *in vitro* was also prevented by low concentrations (10 μgm./ml.) of 'Triton' *W.R.* 1339 and other surface-active agents. In the presence of these substances the blastomeres, which normally fuse to form a compact spheroidal mass, failed to do so and remained discrete and rounded. The concentration required to produce this change was considerably less than that maintained in the blood by Cornforth *et al.*[5], or used in cultures of monocytes by Mackaness[6], which indicates that ova are more sensitive than other tissues to the action of 'Triton'. None the less, normal blastulæ could be recovered from the Fallopian tubes of mice injected intraperitoneally with 25 mgm. of 'Triton' on two successive days shortly after mating. In these animals, however, implantation did not occur, and if the injections were delayed until it had taken place the embryos were aborted or resorbed. A single intraperitoneal dose (10 mgm.) of suramin prevented or interrupted pregnancy in a similar way.

It is possible that this action of 'Triton' is related to the depletion of lipoids of the corpus luteum described by Rees[7]; however, such depletion did not occur in the animals injected with suramin. Nevertheless, both these substances are active in the systems described by Lovelock and Rees[8], so that their action in this case may also be related.

The absence of any action of 'Triton' or progesterone on ova *in vivo* may be due to a failure of the substances to reach the lumen of the Fallopian tubes. If this can be overcome, it may be possible to interrupt the course of pregnancy at the stage of oval cleavage.

The finding of an undescribed pharmacological action of suramin after years of clinical use is disquieting, and suggests the need to test new drugs on pregnant animals.

Influence of Light on Sporulation of Brewing Yeast

It is well known that bottom yeast as used in the brewing industry can scarcely be made to sporulate. Only a few strains produce some spores. This is a handicap in experiments devised to obtain improved yeast by crossing suitable strains.

In this laboratory many of the presporulating and sporulating media described in the literature were tried with rather poor results. On the other hand, the influence of the season was observed: as a rule, more spores were formed in winter and spring.

Winge has shown that the formation of spores indicates a change from the vegetative generation to the generative generation of the life-cycle of the yeast. Now in the higher plants light has a considerable influence on this transformation. There are plants which only flower when exposed to a long period of light, others are short-day plants. Finally, there is a group which is indifferent to light. Influence of light on the sporulation of yeast was therefore investigated.

Several bottom yeasts, which are still in use in breweries, were inoculated in tubes with about 20 ml. of sterilized wort. After 7 days, when fermentation had ceased, the yeasts were transferred to new tubes. After 2 days, when fermentation was vigorous, 1–2 ml. of the wort was transferred to gypsum blocks.

After the wort had penetrated into the gypsum blocks the Petri dishes were provided with sterile tap-water. After 5 days, preparations of the yeasts on a slide stained with malachite green and safranin were examined microscopically.

One set of cultures (the dark set) had been kept in a dark thermostat at 20° C. all the time.

The second set (the long-day set) had been kept in the window. The third set (the short-day set) had been placed in the window from 9 until 17 hr. and for the rest of the time stored in the dark thermostat at 20° C. The dark set was not exposed to light except when being inoculated in normal daylight. The short-day set was subjected to 8 hr. daylight, the long-day set to about 16 hr., as the experiments were performed in May and June.

The culture tubes as well as the gypsum blocks of one set were kept under the same conditions.

Table 1

Yeast	Exposure time (hr.)	No. of cells counted	Percentage vegetative cells	Percentage asci with				Total asci (per cent)
				1 sp.	2 sp.	3 sp.	4 sp.	
G_{2a}	0	566	98·0	0·2	0·9	0·9	0	2·0
	8	605	96·4	0·8	1·0	1·5	0·3	3·6
	16	323	54·5	9·3	13·0	16·4	6·8	45·5
G_5	0	489	57·1	2·0	18·6	9·6	12·7	42·9
	8	610	75·9	2·1	7·0	9·7	5·3	24·1
	16	615	89·5	1·3	3·1	4·3	1·8	10·5
G_{27}	0	601	97·2	1·5	0·7	0·5	0·1	2·8
	8	620	97·7	1·0	1·1	0·2	0	2·3
	16	633	96·6	2·3	0·9	0·2	0	3·4

Three typical examples of the results are given in Table 1.

Sometimes when the experiments were repeated several times the results were identical; although at other times the results were different. Perhaps there is a certain period of sensitivity to light that may have a conclusive influence; but this has not yet been investigated. No doubt there exists an influence of light in inducing sporulation in the yeast strain G_{2a}. In other strains the sporulation is inhibited as shown in the case of strain G_5. The third type is indifferent towards light, as the latter neither stimulates nor inhibits sporulation (G_{27}). This was, however, only found with badly sporulating yeasts. On the other hand, no abundantly sporulating bottom yeast is known.

When the water of the 5-day-old cultures on gypsum blocks was replaced by a 0·1 per cent glucose solution, the sporulation sometimes could be improved without altering the proportion of the results. In one experiment 0·5 per cent sodium acetate produced no improvement.

The experiments will be extended with more exposure times. Where there is a sensitivity towards light, a substance, presumably a pigment, is probably responsible. This is to be investigated. With regard to this substance, the effectiveness of different wavelengths will be also examined.

Some strains show an influence of light on the rate of fermentation. When the cultures of these yeasts are exposed to artificial light during 24 hr. the rate of fermentation is decreased. This inhibition may explain the irregular results which are sometimes obtained.

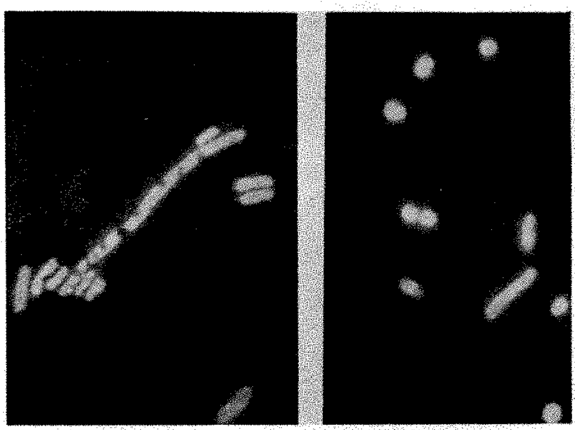
Autolytic 'Protoplast' Release in *Bacterium coli*

We recently discovered accidentally that controlled autolysis of certain Gram-positive bacteria in concentrated sucrose solutions adjusted to a critical ionic strength at *p*H 6 results in the release of the internal protoplasts from the mechanical protection of the cell-wall[1,2]. These 'protoplasts' are stable in suspension media of osmotic pressure above 20 atm., but lyse in more dilute media. The observations of Alfred Fischer[3] and Garbowski[4] on plasmoptysis of certain Gram-negative bacteria in media of low salinity suggested that autolytic release of stable protoplasts might also be possible in these organisms. We have therefore made a preliminary investigation of the conditions required to release the protoplasts of *Bacterium coli* (American strain *B*).



(*a*) (*b*)

Fig. 1. Anoptral contrast micrographs of *Bacterium coli* (*a*) at commencement of incubation and (*b*) after 12 hr. incubation in the controlled autolysis medium (× 4,000)

The development of osmotic fragility—representing loss of tensile strength of the cell-wall—was measured by the degree of lysis of the organisms (depression of light scattering) when pipetted into a buffered medium of low osmotic pressure (0·01 *M* phosphate buffer *p*H 5·8) compared with equivalent samples pipetted into *M* sodium chloride containing the same buffer. Rapid development of osmotic fragility without appreciable lysis of the 'protoplasts' occurs at 25° in 0·3 *M* sodium malonate in 0·5 molal L-arabinose at neutral *p*H. The rate of 'protoplast' release is greater the faster the growth of the organisms at harvesting; and, for exponential phase growth in an aerated 2 per cent tryptone, 1 per cent glucose, 0·1 per cent 'Marmite' medium at 25°, half the organisms become osmotically fragile in less than 60 min.

Anoptral contrast microscopy (Messrs. Reichert, Austria) shows that the organisms are initially strongly plasmolysed in the autolysis medium (Fig. 1*a*). The chains of organisms become shorter as autolysis proceeds; but when complete osmotic fragility is achieved the organisms are still cylindrical. Transformation to spheres commences some hours later (Fig. 1*b*) and nears completion in about 12 hr. Similar results have been obtained with *Aerobacter aerogenes* although sphering is much more sluggish in this organism. It is possible that the plasma-membrane and/or protoplasm of these organisms normally possess enough mechanical rigidity to resist the tendency to assume a spherical shape even when the cell-wall has been lost or has ceased to possess mechanical rigidity.

We are indebted to Mr. R. A. Fox for photography, and to the Scottish Hospital Endowments Research Trust for grants in aid of this work.

Application of Large Volumes in Small Spots on Paper Chromatogram Strips

SEVERAL devices have been designed for continuous application of large volumes up to 5 ml. on chromatogram strips[1,2]. The diameter of the spots thus obtained is usually 1 cm. or more, and considerable time is needed.

In order to apply relatively large volumes in very small spots on narrow paper strips in a reasonably short time, the following apparatus was constructed, in which a strong centripetal stream of warm air is concentrated around the place of application on both sides of the paper.

The apparatus is made of glass and consists of two parts (Fig. 1).

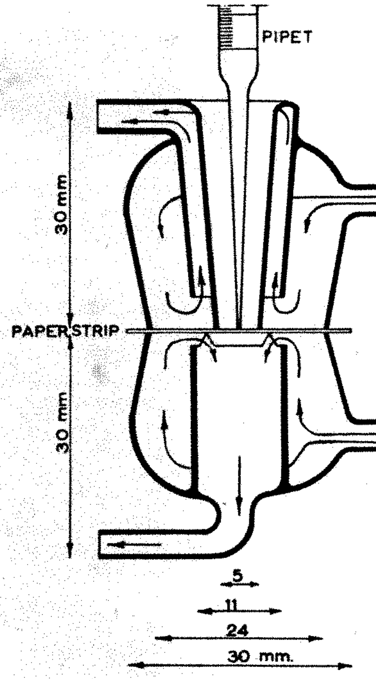

Fig. 1

The upper part is made of three concentric tubes, of diameters as indicated, fused together at the top. The middle tube is 2 mm. shorter than the other two, which have been ground down afterwards so as to end at exactly the same level. An air inlet is fused to the outer tube, the outlet is between the middle and the innermost tube.

The lower part is made symmetrical with the upper part, but without the innermost tube. The inner tube is again shorter than the outer one by 2 mm. and provided with four small points, the ends of which have been made level with the rim of the outer tube by grinding.

The paper is firmly held in its place by the rims of the two outer tubes of the innermost tube of the upper part, and the points of the inner tube of the lower part. The two parts are held together by slightly flexible rubber joints on the air inlet.

In this way even very narrow chromatogram strips 6 mm. wide can be used, when a paper mask is inserted. The tip of the applying burette or pipette is put on to the paper by entering it into the innermost tube of the upper part, and is protected by it from the air stream.

Air is blown through the apparatus from the compressed-air main after passing a filter and a heated copper spiral. A thermometer permits control of temperature.

The solution can be applied by means of a microburette of the Scholander or Rehberg–Kirk[3] type or by means of an Agla microsyringe. Thus outflow of solution, air stream and air temperature can all be controlled.

The time needed for application depends on the paper, the temperature used, and the volatility of the solvent. With various sorts of paper and solvents very small spots can be obtained in a reasonably short time: dilute solutions can be applied in a spot of 4–5 mm. diameter at a rate of 0·1 ml. in less than 10 min. for water, and less than 5 min. for butanol at 50° C. It is more convenient to condense volumes larger than 1 ml. by evaporation before application.

Chromatography of Insulin on Calcium Phosphate Columns

Swingle and Tiselius[1] investigated the behaviour of the protein phycoerythrin when subjected to chromatography on columns packed with hydrated tricalcium phosphate supported on kieselguhr. It was found that the protein could be displaced by low concentrations of phosphate buffer. In a further study by Tiselius[2] it was found that other proteins could be displaced to give sharp elution zones when using aqueous solutions containing sodium phosphate.

The purpose of this communication is to record some results obtained when solutions of insulin stored under various conditions were subjected to chromatography on calcium phosphate–kieselguhr filled columns, eluting with sodium phosphate buffer of linearly increasing concentration.

The method used for the preparation of the calcium phosphate gel was essentially that of Keilin and Hartree[3], and each column contained 40 ml. gel supported on 26 gm. kieselguhr. The insulin was adsorbed at low ionic strength and eluted with the phosphate gradient increasing from zero to 0·05 *M* (*p*H 7·3) over a volume of 150 ml.; the concentration was then maintained at 0·05 *M*. The eluting solvent contained 0·5 per cent sodium chloride. Fractions of 3·5 ml. volume were collected and the optical density of each fraction at 276 mμ determined on a Unicam *SP* 500 instrument.

When the insulin solution was freshly prepared, the protein was eluted as a reasonably sharp peak (insulin 1) showing evidence of tailing. Any preservative such as phenol was only slightly, if at all, adsorbed and was eluted as a band ahead of the insulin. When the insulin solution was stored for a period of time in acid solution before subjecting to chromatography, it was found that a fraction of the insulin was transformed to a modification (insulin 2) which was eluted behind the band originally observed. On increasing the period of storage, the fraction of insulin changed increased still further. This effect is illustrated by

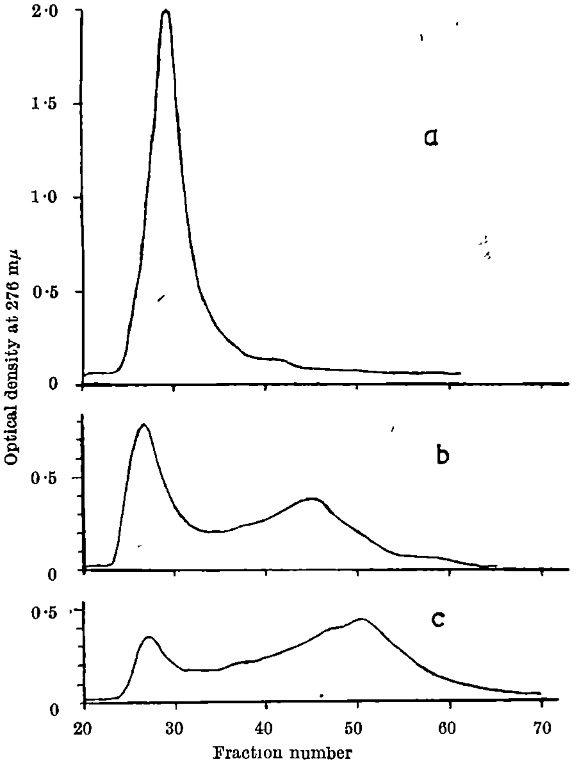

Fig. 1

the accompanying elution curves (Fig. 1), for insulin solution freshly prepared (*a*), and when stored for four days (*b*) and eight days (*c*), at 40° C. and *p*H 3·0.

Insulins 1 and 2 were isolated after elution and subjected again to chromatography, when it was found that each gave its appropriate peak on the elution curves. Bio-assay of materials isolated from the two peaks indicated that insulin 2 retained most, if not all, of the original potency in spite of the marked difference in chromatographic behaviour. A mouse assay gave the ratio of the potency of insulin 2 to insulin 1 as 0·92 ($p = 0·95$, limits 0·827 and 1·03).

It was found that the decrease in concentration of unchanged insulin, as represented by the area under the first insulin peak of the elution curve, followed first-order kinetics, at least for the early stages. Experimental values obtained for the half-life for the transformation of insulin 1 to insulin 2 at *p*H 3·0 and various temperatures are given in Table 1.

These values correspond to an energy of activation of 25,000 cal./mole. The rate of reaction is increased by lowering the *p*H and decreased by increasing the *p*H of the solution for storage. It appears to be affected only slightly, if at all, by sodium chloride concentration, by increasing the zinc concentration, or by removing the zinc from the insulin.

Preliminary results from Dr. Johnson and Mr. Rowe, of the Department of Colloid Science, Cambridge, who are investigating the two fractions, have indicated that a molecular-weight change may be associated with the transformation of insulin 1 to insulin 2.

Table 1

Storage temperature (° C.)	Half-life
0–4	3 0 years
30	14 8 days
40	3 84 days
50	1 11 days
60	10 6 hours

Further work is in progress on this effect, and it is hoped to publish detailed results in due course. I wish to thank Mr. W. Brown for assistance with the experimental work, Mr. K. L. Smith for the bio-assay, and the directors of Boots Pure Drug Co., Ltd., for permission to publish this communication.

An Improved Method for the Preparation of Sialic Acid or Acetylneuraminic Acid

Although two decades have passed since the discovery of sialic acid by Blix[1], few investigations on this acid have been reported, due possibly to the difficulty of the preparation of the acid and the small yield. Recently Odin[2] reported a modified method for the preparation of sialic acid by mild acid hydrolysis in good yield instead of the old method, in which 'water hydrolysis' was employed. I have found that sialic acid is almost quantitatively adsorbed on activated charcoal, and this provides a convenient method for its preparation in good yield.

30 gm. of bovine submaxillary mucin were heated in 30 ml. of distilled water in a sealed tube for 2 hr. at 100° C. After cooling, the solution was dialysed against distilled water for 20–24 hr., changing the water three times during dialysis. The dialysate showed not only a positive direct Ehrlich reaction and Fehling test, but also the biuret reaction. However, the Molisch reaction was negative. The combined dialysate was concentrated *in vacuo* to about 50 ml. The solution became slightly pink during the concentration. The concentrated solution was then passed through an activated charcoal (about 150 mesh) column (2 cm. × 10 cm.). The effluent solution was colourless and was negative in the direct Ehrlich reaction. Thus sialic acid had been quantitatively adsorbed on charcoal. The column was washed with 100–150 ml. of water, and no sialic acid was lost from the column. After removal of the washing water, sialic acid was eluted with 180 ml. of 98–99 per cent methanol. Sialic acid was scarcely eluted at all with ethanol. The effluent solution was evaporated *in vacuo* to dryness. The residue, which did not show the biuret reaction, was dissolved in dry methanol and filtered into a centrifuging tube, and dry ether was carefully added to the filtrate, producing a flocculent precipitate. When no more flocculent precipitate occurred on adding ether, the precipitate was centrifuged off. The volume of ether needed did not exceed that of the methanol solution. Dry petroleum ether (about 5 ml.) was added dropwise to the clear colourless supernatant solution, whereupon the solution became turbid. On allowing to stand in an ice-box, crystalline sialic acid appeared on the glass wall. The form of the crystal was similar to that reported by Blix[1], and the yield was about 350 mgm. from 30 gm. of the mucin. The nitrogen

content was 4·1 per cent; the same value was obtained for every preparation. Other chemical properties of the crystal were identical with those of bovine sialic acid described by Blix. The specific rotation of the crystal, however, was different from that of bovine sialic acid reported by Blix: according to Blix[3] bovine sialic acid has the value of $[\alpha]^{23}_{D} = +8 \pm 2°$; whereas my sample showed $[\alpha]^{20}_{D} = -42 \cdot 0°$ (in water) after 10 min. and $-32 \cdot 8°$ after 30 min. The value of the specific rotation extrapolated to zero time was $-50°$. Thus mutarotation was observed with the substance. This evidence accords with the assumption of the presence of a potential aldehyde group in sialic acid[4,5].

From the optical rotation and nitrogen content of the product I have obtained it seems to be identical with Klenk's acetylneuraminic acid[6] and sheep sialic acid[3]. Recently, Klenk *et al.*[7] stated that acetylneuraminic acid should be identical with sheep sialic acid. Whether the product I have obtained is natural bovine sialic acid or not is not yet certain. It may be a slightly decomposed bovine sialic acid. Although bovine sialic acid was distinguished from neuraminic acid by the aid of colour reaction[5], Blix's authentic bovine sialic acid (kindly provided by Prof. Blix) could not be distinguished from my product by colour reaction.

The details of this investigation will appear elsewhere; further experiments are now in progress.

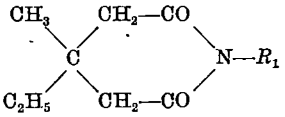
New Analeptics and Hypnotics related to the Barbiturate Antagonist, 'Bemegride'

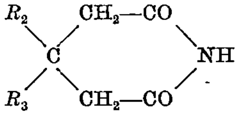
THE preparation of various glutarimides in these laboratories for testing as possible analgesics led to the discovery[1] in the Department of Pharmacology and Physiology, University of Melbourne, of the antibarbiturate activity of ββ methyl ethyl glutarimide ('Bemegride', 'Megimide'), from which a new method of treatment for barbiturate intoxication has been developed[2]. This prompted the investigation of related β-substituted glutarimides and derivatives of 'Bemegride' for similar activity. A series of compounds was therefore synthesized for examination, and the results of preliminary pharmacological trials are reported here.

The effects of the test compounds on the sleeping times induced by pentobarbital sodium in mice were compared with that of 'Bemegride', using groups of ten mice. The control group received 60 mgm./kgm. pentobarbital sodium. The test group received pentobarbital sodium (60 mgm./kgm.) and the test compound (25 or 50 mgm./kgm.), followed by further injections of the test compound at the same dosage at 15 min. intervals. The third group received pentobarbital sodium (60 mgm./kgm.) and 'Bemegride' (25 mgm./kgm.), followed by further injections of 'Bemegride' as for the test group. The control group received injections of distilled water at similar intervals. All injections were intraperitoneal. Where the compounds were too insoluble for administration in aqueous solution, suspensions in 1 per cent gum tragacanth were used. The sleeping time was the time elapsing between loss and recovery of the righting reflex. Where any appreciable reduction (50 per cent or more) in mean sleeping time was observed, a *t*-test was applied.

The two hydrolysis products of 'Bemegride', ββ methyl ethyl glutaramic acid and ββ methyl ethyl glutaric acid, were found to be ineffective as barbiturate antagonists. Three N-substituted derivatives of 'Bemegride' (I where R_1 = Me, Et and Ph) were also found to be inactive.



(I)



(II)

Fourteen other β-substituted glutarimides of type (II), where R_2, R_3 = H, H; Me, H; Me, Ph; Et, H; Ph, H; Et, Et; Pr, Pr, and the series of ββ methyl alkyl glutarimides, where R_2 = Me and R_3 = Me, *n*-Pr, *n*-butyl, *i*-butyl, *n*-amyl, *n*-hexyl and *n*-heptyl, together with the β spiro cyclopentane, cyclohexane and cycloheptane glutarimides, were then examined for analeptic activity.

Three compounds, the β spiro cyclopentane, ββ methyl *n*-propyl and ββ diethyl glutarimides, were found to have similar analeptic effect to that of 'Bemegride', the relative activities being in the order named. The cyclopentane compound was almost as effective as 'Bemegride' at the same dose-level (25 mgm./kgm.) in producing a 50 per cent reduction in sleeping time, while the other two produced the same result when administered at 50 mgm./kgm. (*t*-tests gave $P < 0 \cdot 01$ in all cases). Like 'Bemegride', all three caused convulsions in mice when injected alone at doses of 15–50 mgm./kgm., the cyclopentane and diethyl compounds being lethal at 20 and 75 mgm./kgm. respectively. The methyl *n*-propyl compound is less toxic and at doses up to 400 mgm./kgm., induced periodic convulsions for upwards of one hour, when the animals usually recovered.

The β ethyl, ββ methyl *iso*butyl and the other two β spiro cycloalkane glutarimides were also convulsants when administered alone at 20–50 mgm./kgm. Treatment of the animals with pentobarbital before injection of any of these compounds prevented convulsions in all cases; but the sleeping times were not affected.

ββ Methyl *n*-butyl glutarimide was found to have hypnotic effects in mice, its action being opposite to that of the convulsant methyl *iso*butyl compound. The methyl *n*-amyl and methyl *n*-hexyl glutarimides were also found to have hypnotic activities, while the methyl *n*-heptyl compound had no apparent pharmacological action.

These three hypnotic glutarimides, being rather insoluble in water, were administered as suspensions in 1 per cent gum tragacanth. For all three compounds, the minimum hypnotic dose is 150–200 mgm./kgm. and the approximate *LD*50 is 600 mgm./kgm. Using groups of ten female albino mice, the mean sleeping times induced by each compound at a dose

Table 1

-glutarimide	Dose level (mgm./kgm.)	No. losing righting reflex	Mean induction time (min.)	Sleeping time (min.) Mean ± S.E.
ββ Methyl *n*-butyl-	200	7	7	3·5 ± 1·23
	300	10	6	23 1 ± 2·75
ββ Methyl *n*-amyl-	200	10	5	42·3 ± 6·02
ββ Methyl *n*-hexyl-	200	10	9	17 0 ± 2 62

of 200 mgm./kgm. were obtained, and are listed in Table 1.

The methyl *n*-amyl compound thus appears to be the most effective of the three. No signs of toxic effects were observed at these doses. Sleeping times up to 5 hr. were induced with all three hypnotics at doses of 400–500 mgm./kgm.

Finally, it has been shown, by the procedure used for screening the other test compounds, that the hypnotic action of these three glutarimides is very effectively antagonized by the methyl ethyl glutarimide, 'Bemegride'. Of a group of ten mice injected with 200 mgm./kgm. of the methyl *n*-amyl compound followed by a single injection of 20 mgm./kgm. 'Bemegride', five did not lose the righting reflex at all, and the mean sleeping time of the remaining five was reduced to less than one-third the control value. No convulsions were observed, indicating a swift antagonism between the two glutarimides in the animals.

From the pharmacological results so far obtained the following conclusions regarding the activity of 'Bemegride' as a barbiturate antagonist are evident. (1) The intact glutarimide ring is essential for analeptic effect, as the two hydrolysis products have no activity. (2) The inactivities of the *N*-substituted derivatives of 'Bemegride' demonstrate the importance of the imido hydrogen atom. (3) 'Bemegride' is not unique among β-substituted glutarimides as a barbiturate antagonist, as three closely related compounds have been shown to have similar activities.

In the series of β methyl β *n*-alkyl glutarimides, which contains two analeptic compounds, 'Bemegride' and ββ methyl *n*-propyl glutarimide, further extension of the *n*-alkyl substituent to butyl, amyl and hexyl results in hypnotic activities in these three compounds. 'Bemegride' effectively antagonizes the hypnotic effect in mice of these glutarimides. The methyl *n*-heptyl glutarimide, however, has no particular activity.

Work is continuing on compounds of the glutarimide type, and further pharmacological results, together with complete chemical information, will be published shortly.

I should like to thank Prof. F. H. Shaw, of the Pharmacology Department, University of Melbourne, who allowed me to use the facilities of that Department for some of the earlier testing, and also the directors of Nicholas Proprietary, Ltd., for permission to publish this communication.

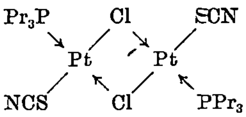
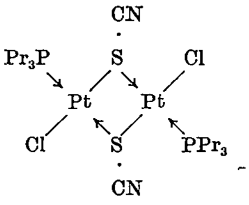
Use of the Infra-Red Spectrum to distinguish Bridging from Terminal Thiocyanato-S-Groups in Co-ordination Compounds

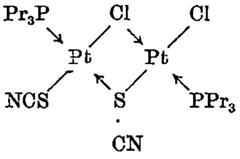
In 1952 the existence of two thiocyanato-complexes of composition $(PPr^n_3)_2Pt_2Cl_2(SCN)_2$ was reported[1]. The labile α-isomer had m.p. 144°–152° and the stable β-isomer, m.p. 173°–174·5°. These isomers have dipole moments of less than 2 Debye units and so must have the tri-*n*-propylphosphine groups in *trans*-positions to each other. Possible structures are (I), (II) and (III).



(I)



(II)



(III)

A substance of structure (II) might also exist in two geometrically isomeric forms, according to whether the CN groups are in *cis* or in *trans* relationship to each other about the planar PtS_2Pt ring. Since such geometrical isomerism, arising from the aplanarity of the valencies from the 3-covalent sulphur atoms, was then unknown, it was considered that the α- and β-isomers would most probably be structural isomers, and from general considerations of their relative stabilities they were assigned structures (I) and (II) respectively. At that time no means of confirming or disproving that assignment of structures was available to us; but now using infra-red methods we conclude that both isomers have their SCN groups in bridging positions, and so cannot be the structural isomers at first postulated.

We find that the infra-red spectrum affords an excellent method of determining whether thiocyanato-S groups are in terminal or in bridging positions. This conclusion is based on the examination of a number of thiocyanato-complexes of platinum (II) and of palladium (II). The spectra were obtained from paraffin oil mulls of the powdered crystalline complexes using a Grubb-Parsons *S3A* spectrometer fitted with a lithium fluoride prism. The observed frequencies (to the nearest cm.$^{-1}$) are listed in Table 1. All the thiocyanato-complexes which we have studied exhibit at least one strong absorption band in the region of 2,100–2,170 cm.$^{-1}$, and this can be unequivocally assigned to the SCN stretching modes. The particular modes are presumably derived[2] from ν_3 of SCN^-, which has[3] a frequency of 2,066 cm.$^{-1}$. All the mononuclear complexes have an absorption band in the range 2,100–2,120 cm.$^{-1}$, and those binuclear complexes which from their composition must contain both bridging and terminal SCN groups have additional bands in the range 2,150–2,182 cm.$^{-1}$. It is evident that bridging SCN groups give rise to

Table 1. STRONG ABSORPTION BANDS IN THE 4μ REGION OF THE SPECTRA OF SOME THIOCYANATO-COMPLEXES OF PLATINUM AND PALLADIUM

Compound	Bridging SCN	Terminal SCN
$(AsPr^n{}_3)_2Pd(SCN)_2$	—	2,115

α-$(PPr^n{}_3)_2Pt_2(SCN)_2Cl_2$	2,162	—
β-$(PPr^n{}_3)_2Pt_2(SCN)_2Cl_2$	2,169	—

* Dipy = 2 : 2′-dipyridyl

stretching frequencies about 30–80 cm.$^{-1}$ higher than the corresponding frequencies originating from terminal SCN groups, and that all the complexes of the type $L_2M_2(SCN)_2Cl_2$ (L = $AsAlk_3$ or $PAlk_3$; M = Pd or Pt) which we have investigated have both their thiocyanato-groups bridging the two metal atoms.

This conclusion rules out the original proposal that the α- and β-forms of $(PPr^n{}_3)_2Pt_2Cl_2(SCN)_2$ are the structural isomers (I) and (II) and points to both having the structure (II). On this basis the two isomers can only be accommodated if they are the geometrical isomers discussed above, and would provide the first example of such isomerism. Against this it can be argued that all SCN stretching modes of the *cis*-form of (II) should be infra-red active and hence its spectrum should have two bands in the neighbourhood of 2,160 cm.$^{-1}$, whereas we observe only one. However, in complexes containing heavy metal atoms accidental degeneracies may easily occur and prediction from group theory concerning the numbers of bands which should occur in the infra-red spectrum can be misleading. As evidence for this we have the single absorption band in the spectrum of the dipyridyl complex which cannot be centrosymmetrical. It is proposed to investigate these points more fully.

The difference between the SCN stretching frequencies of the bridging and terminal groups is in the sense to be expected if it were caused by electronic effects. The valence force treatment of the SCN^- ion given by Penney and Sutherland[2] indicates that the frequency of the 4μ band is determined to a large extent by the CN bond-stretching force constant. The CN bond order will increase with increasing positive charge on the sulphur atom, and so the frequency of the 4μ band should be greater when the sulphur atom is co-ordinated to two metal atoms than when it is only co-ordinated to one, as we observe.

Vapour Pressures of Some Disperse Dyes

THE vapour pressure, heat and standard entropy of sublimation of two disperse dyes, 1-methylaminoanthraquinone and 1-(β-hydroxyethyl)aminoanthraquinone, have been determined.

Vapour pressures of the former were determined over the temperature range 110°–130° C., and of the latter over the range 150°–165° C., by a modification[1,2] of Knudsen's effusion method. The vapour effused through a hole of known area into a hard vacuum and was condensed on a cold finger. The rate of effusion was measured by observing, by means of a cathetometer, the deflexion of a silica spring from which was suspended the effusion vessel. This vessel had been previously calibrated at approximately 40° C. by using benzophenone, the vapour pressure of which has been accurately determined by Neumann[3]. As a check, a second vessel containing a hole of smaller area was also used, and the results agreed within the experimental error. The method assumes that the effusing vapour is monomolecular.

The dyes were purified by chromatography and sublimation *in vacuo*. Spectrographic analysis of material sublimed in the temperature ranges, as above, shows that no decomposition of the material takes place under these conditions.

On plotting $\log_{10}p$ (cm. of mercury) against $10^3/T$, where T is the absolute temperature, the results were found to fit the equation

$$\log_{10}p = \frac{a}{T} + b$$

Data for the two dyes are given in Tables 1 and 2.

	1-Methylaminoanthraquinone	1-(β-Hydroxyethyl)aminoanthraquinone
Heat of sublimation (kcal. mole^{-1})	30·85	36·50
Standard entropy of vaporization for vapour at one atmosphere (cal. mole^{-1} deg.$^{-1}$)	52 87 (±0·30)	59·24 (±0 01)

Majury[4] has shown that, in the case of five 'model' dyes, namely, *p*-nitroaniline, NN-dimethyl-*p*-nitroaniline, azobenzene, *p*-aminoazobenzene, and NN-dimethyl-*p*-aminoazobenzene, from a knowledge of vapour pressures and dyeing adsorption isotherms from the vapour phase, the absolute heat of association of the model compound with the substrate can be found.

In the present work, the compounds used are actual dyestuffs with much smaller vapour pressures, and it is hoped, eventually, to correlate these results with data on the energy and entropy of adsorption of the dye vapour on suitable substrates, and with data on the diffusion of dyes in such media.

Oxidation-Reduction Reactions of Metal Salts in Non-aqueous Solvents

THE recent exploitation of electron exchange reactions in aqueous solutions[1] has provided valuable information on oxidation-reduction reactions in general and stimulated their study. The situation for the latter reactions in non-aqueous solvents is completely different, little being known about them despite their importance in trace-metal catalysed autoxidations[2]. Collinson and Dainton[3] have pointed out that radicals produced during polymerization will react with a variety of metal salts in a number of media. Useful comparative data can also be obtained by studying the reactions of metal salts with a stable free radical. In this instance the reactions between metal acetates and the radical αα′-diphenyl-β-picrylhydrazil have been investigated. First-order kinetics for each reactant were observed; below are listed specific rate constants for reactions in anhydrous acetic acid at 25° C.

Metal acetate	Specific rate constant (M^{-1} sec.$^{-1}$)
Lead (IV)	35
Cobalt (III)	22
Cerium (IV)	55
Iron (III)	88

Other acetates, namely, those of chromium (III), copper (II) and manganese (III), also react with the free radical, but kinetic data are not available yet. In all these reactions the rate was reduced by the addition of methyl alcohol or benzene but increased markedly by the addition of water.

Further interesting reactions were found to occur between valence states of metal acetates; again, anhydrous acetic acid was the main solvent used. The systems which were examined in detail are lead (IV)–cobalt (II), lead (IV)–cerium (III) and lead (IV)–manganese (II); first-order dependence on all the reactants except manganous acetate was observed. Below is a table of apparent activation energies and specific rate constants for these systems.

	Specific rate constants (M^{-1} sec.$^{-1}$)	Activation energies (kcal./mole)
Lead (IV) + cobalt (II)	0·56	14 ± 1
Lead (IV) + cerium (III)	0·24	21 ± 1
Lead (IV) + manganese (II)	0·43	14 ± 1

Attempts are being made to identify the reacting species by noting the effect of the addition of other solvents and unreactive salts on the reaction-rates, absorption spectra and ion migrations with an applied potential. For example, in the lead (IV)–cobalt (II) reaction addition of water retarded the reaction-rate whereas sodium acetate accelerated it; both these additives affected the absorption spectrum of cobaltous acetate markedly; with added water, migration to the cathode only was observed, but when sodium acetate was present instead, migration to both anode and cathode occurred.

Preliminary work has shown that reactions between the valence states of the acetates of chromium, copper, mercury and iron also take place in dry acetic acid. In addition, chromous acetate may be oxidized to the chromic state in methyl alcohol by some metal acetates.

Crystal Structure of 1 : 2-Benzanthracene

As part of an investigation into Daudel and Pullman's theory[1,2] concerning the connexion between carcinogenic activity and the chemical structure of benzanthracene derivatives, we have made a detailed study of the crystal structure of 1 : 2-benzanthracene.

Crystal studies of this substance have been reported previously by Iball[3], who, however, appears to have obtained a *c*-crystal axis dimension which is twice the length we have found.

As already reported by Iball, 1 : 2-benzanthracene is very difficult to obtain in crystals suitable for single-crystal analysis. We have found that a dilute solution of benzanthracene in a mixture of 1/3 methanol to 2/3 ethanol, which is allowed to evaporate slowly (24 hr.) at room temperature, will deposit perfect, but very small, crystals (0·1 mm. × 0·3 mm. × 0·5 mm.). Slowing down the rate of evaporation did indeed enable one to obtain larger crystals, but single-crystal photographs of these invariably showed them to be twins.

We have carried out a three-dimensional Fourier analysis of 1 : 2-benzanthracene in order to measure

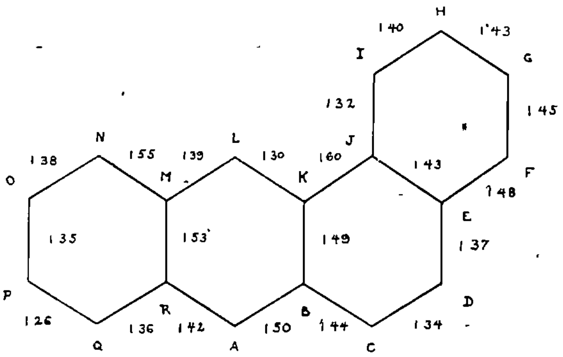

Fig. 1

the bond-lengths and electron densities of the *K*-region, so named by Daudel and Pullman[1].

Because of the lack of a centre of symmetry in three dimensions, the total absence of atomic resolution in the only centrosymmetric projection (*h0l*), and the low percentage of measured reflexions (518 out of a permitted total of 1,658), the refinement of the structure has been difficult and is not yet complete. For this reason the bond-lengths (in A.) shown in Fig. 1 are only tentative. To date, the refinement has consisted of three rounds of three-dimensional Fourier refinement (for which our thanks are due to Prof. R. Pepinsky, who very kindly allowed us to use *X-RAC*) and nine rounds of three-dimensional least-squares refinement carried out on the *IBM* 701 computer and Remington Rand's *UNIVAC*. The structure now has a discrepancy *R* of 21·5 per cent over the 518 planes. The molecule is planar within experimental error. Further work is in progress to improve the discrepancy, and full details will be reported later.

We are grateful for a U.S. Public Health Service grant.

Absorption of Oxygen and Carbon Monoxide by Barium Alloy Getters

WAGENER[1] has described a novel method of finding both the pumping speed and capacity of getters, and has made measurements[2,3] with common gases and barium alloy getters of the type used in radio valves. The results obtained were conflicting. In the earlier paper[2] it was reported that the speed of pumping depended upon the amount of ionizing electron current in a nearby diode or ionization gauge. Wagener's measurements were made in a range of electron current from 5 m.amp. to 20 m.amp. If these measurements are extrapolated to zero current they show that the speed of pumping is not then zero, contrary to the hypothesis suggested in the paper. In the later publication[3] it was reported that the speed of pumping was about the same without, as with, an ionizing electron discharge. The present work was undertaken to decide between these contrary findings. It was decided to study the pumping of oxygen, because the chemical affinity of barium for this gas would make more remarkable any necessity for electron current.

The apparatus used here was similar to that described by Wagener[1-3], except that, for measuring pressures without using any ionizing electron current, a Pirani gauge was fitted. In addition, pressure measurements could be made with the ionization gauge over a range of electron current, from less than 1 microamp. to more than 1 milliamp. During most of the present experiments, the pressure above the getter was of the order 10^{-6} mm. mercury. The barium alloy getters used were of the *KIC* type, 20 mgm. size, with a non-magnetic stirrup, as in television tubes.

It was found that the speed of pumping of oxygen by a barium getter film was very little changed when an ionizing (180 V.) electron current was run nearby. A typical set of values of speed and current was as follows:

Electron current (μamp.)	0	1	5	10	50	100	500	1,000
Speed of pumping (l.sec.$^{-1}$)	1 50	1·50	1·50	1·50	1·52	1·54	1·67	1·85

The slight variation of speed with current was linear. Thus barium getters pump oxygen in the absence of any ionization.

The speed of pumping of the getters was found to vary with time, as had already been reported by Wagener[2]. The variation of the speed of pumping with time and temperature is shown in Fig. 1. The increase of speed with temperature should be noted. Moreover, the amount of oxygen taken up by the getter (capacity) increased with temperature. At room temperature the capacity was independent of the thickness of the getter film deposited, so that thick films were still opaque and metallic-looking when pumping ceased. At higher temperatures the capacity increased with the thickness of the film, and the deposit became translucent at the end of pumping. These results show that the mechanism of gettering involves diffusion.

In spite of ionization not being necessary for the pumping of oxygen by barium, it was suspected that the hot filament in an ionization gauge might influence the speed of pumping. The measurements of the variation of the speed of pumping of oxygen, with electron current, were made with the getter film at room temperature, while the speed was not changing with time. However, it was found, from Pirani gauge measurements, that during the falling-speed period, towards the end of the life of a getter film, all pumping ceased if an incandescent tungsten filament near the getter was switched off. The tungsten filament became effective when its temperature was raised above 1,800° K.; but increasing the temperature to 2,100° K. did not increase the speed further. Moreover, the speed was not raised further by increasing the number of filaments that were heated. Thus, some product of the interaction of oxygen molecules with an incandescent tungsten filament, probably atomic oxygen, has a catalytic effect upon the taking up of oxygen by a failing barium getter film.

A considerable increase of speed of pumping and of capacity with temperature was also found in experi-

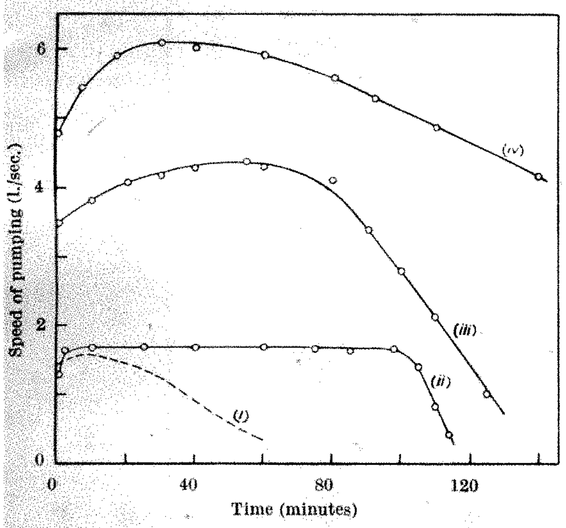

Fig. 1. Variation with time and temperature of the speed of pumping of oxygen by barium. Curve (i) represents Wagener's work, with an area of 12 sq. cm. at an unknown temperature. The present work is with an area of 8 sq. cm. at the following temperatures: (ii) room temperature; (iii) 40° C.; (iv) 70° C.

ments with carbon monoxide. This result contrasts with the small increase reported by Morrison and Zetterstrom[4]. The increased capacity was marked by the getter film becoming translucent, although stained brown.

I wish to thank Mr. M. E. Haine and Mr. B. M. Cox for much help, and Dr. T. E. Allibone, director of this laboratory, for permission to publish this communication.

Change in Surface Area of Anthracite on Heat Treatment

Maggs[1] and Malherbe[2], among others, have shown that coal behaves as a molecular sieve material. That is, the adsorption of nitrogen and argon at 77° K. is restricted because of activated diffusion into pores of molecular dimensions and gives data only on the readily accessible macropore area of coal. From heats of wetting and gas-adsorption data at higher temperatures, the macropore area is shown to represent an insignificant part of the total surface area of most coals.

The presence of a large micropore area in coal affects many of its properties. One property which is thought to be markedly affected is the thermal stability of anthracite on pyrolysis. Raw anthracite when used as a metallurgical fuel is susceptible to thermal shock, usually resulting in the lowering of its physical strength and subsequent size degradation. This phenomenon is thought to be primarily caused by the large increase in gas pressure in the micropores produced by the difficulty of releasing volatile matter from these pores upon heat treatment. It is with this thought in mind that a comprehensive programme has been initiated to study the nature of the micropore surface area in anthracites, its change with heat treatment, and its relation to decrepitation. An initial result of interest is being reported at this time.

The anthracite studied has the following proximate analysis on the as-received basis: water, 3·4 per cent; volatile material, 2·9 per cent; ash, 7·1 per cent; free carbon, 86·6 per cent; and sulphur, 0·54 per cent. Adsorption studies were performed on minus-60 mesh samples (Tyler series) of raw and calcined anthracite. Calcination was conducted in a reducing atmosphere with samples heated to 1,200° C. in two hours and maintained at this temperature for two additional hours. Surface areas of the anthracite were determined from nitrogen adsorption at 77·2° K. and carbon dioxide adsorption at 194·6° K. using the procedure and Brunauer–Emmett–Teller equation discussed by Emmett[3]. Final adsorption pressures were read after 30 min. even though equilibrium was not completely attained.

Table 1 presents the surface area data. The nitrogen value can be considered essentially the macropore area, whereas the carbon dioxide value can be considered essentially the total area. The nitrogen value would be expected to consist of some micropore area, and the carbon dioxide value would be expected to be somewhat less than the total area since equilibrium was not reached. Naturally, any arbitrary adsorption time of reasonable duration has the above limitations, and this fact must be kept in mind when interpreting the data. It should also be pointed out that good agreement of surface areas from nitrogen and carbon dioxide adsorption on carbons known to have an insignificant microporosity has been obtained[4].

Table 1. SURFACE AREA OF RAW AND CALCINED ANTHRACITE

Treatment	N_2 area, m.²/gm.	CO_2 area, m.²/gm.
Raw	11·2	175
Calcined	0·78	2·8

It is seen that for the raw anthracite the micropore area represents at least 93 per cent of the total area, whereas for the calcined material only somewhat more than 72 per cent need be in micropores. Of greater significance is the marked decrease in the magnitude of micropore area upon calcination. At least 98 per cent of the micropore area has been destroyed or blocked from access to the exterior surface on calcination at 1,200° C.

Calcination of the anthracite produced approximately a 15 per cent volume-shrinkage. In the light of the area results, it appears that this shrinkage parallels the removal of the majority of micropore area from the anthracite. Indeed, anthracite which has been calcined at a very low heating rate[5] shows good thermal stability when afterwards plunged rapidly into a hot zone, which is to be expected if the microporosity and occluded gases have been removed.

The Golgi Apparatus and Secretion of Enzymes in Peptic Cells of Rabbit

IN rabbits starved for 48 hr. with free access to water, the Golgi apparatus as shown by the Aoyama technique, as modified by me, is in the form of a compact reticulum lying close to the luminal pole of the nucleus (Fig. 1.1). After feeding, the Golgi reticulum expands and increases gradually in volume until it occupies the luminal part of the cytoplasm (Fig. 1.2–4). During increased secretory activity, the power of the Golgi substance to reduce silver nitrate or osmium tetroxide gradually increases ; this suggests that besides the morphological changes, chemical changes occur in the Golgi substance. In the fed rabbits, argentophile secretory granules appear in the field of the Golgi apparatus, and as the latter hypertrophies the secretory granules increase in number (Fig. 1.2–3).

Most of the secretory granules are seen in close association with the Golgi substance ; those which have moved away from the Golgi apparatus field are present above it in the supranuclear region which is usually free from mitochondria. The granules when secreted are argentophile ; then they increase in size and loose their argentophily. Some of these argentophobic granules run together, forming larger spheres which ultimately accumulate at the luminal part of the cytoplasm.

It is worth mentioning that subsequent to feeding, the argentophile granules were observed in the cells ; but after approximately two hours they were less frequently seen, and instead of them non-argentophile larger granules were observed. Some of these argentophobic granules were seen to be encircled either partly or completely by the Golgi substance (Fig. 1.4) ; this is well illustrated in the photomicrograph (Fig. 2), where argentophobic spheres (*Z*) lie in the claw-like prolongations of the Golgi substance ; this indicates that the argentophile material represents an early stage in the formation of the non-argentophile secretion granules, and that the process of transformation of young secretory granules to mature zymogen takes place in contact with the apparatus of Golgi.

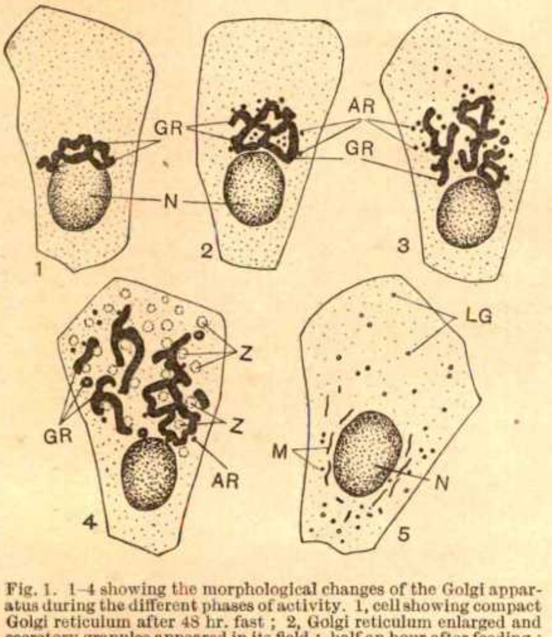

Fig. 1. 1–4 showing the morphological changes of the Golgi apparatus during the different phases of activity. 1, cell showing compact Golgi reticulum after 48 hr. fast ; 2, Golgi reticulum enlarged and secretory granules appeared in its field ; half an hour after feeding ; 3, cell in an advanced stage of secretion ; one hour after feeding ; 4, cell showing the transformation of some of the argentophile secretory granules (propepsinogen) into non-argentophile pepsinogen spheres ; 5, a composite cell showing lipid granules (drawn here as spheres) and mitochondria

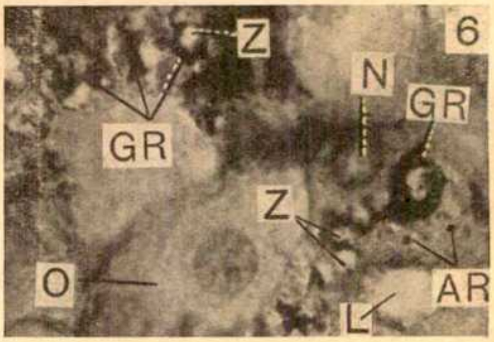

Fig. 2. A photomicrograph showing argentophile propepsinogen granules and non-argentophile pepsinogen globules which are encircled either partly or completely by the Golgi substance ; two hours after feeding. *AR*, argentophile secretory granules (propepsinogen) ; *GR*, Golgi reticulum ; *L*, lumen of gastric gland ; *LG*, lipid granule ; *M*, mitochondria ; *N*, nucleus ; *O*, oxyntic cell ; *Z*, non-argentophile pepsinogen globules

In rabbits which had constant access to food the Golgi apparatus presents great variations in appearance, which indicate that the cells are in different phases of activity and that each cell appears to act as an independent unit.

I consider the argentophile granules, which appear after the intake of food, as the young or prozymogen (propepsinogen) granules ; these are transformed into mature secretory granules (zymogen or pepsinogen) which are non-argentophile. None of the prozymogen or zymogen granules appears to stain vitally in neutral red, methylene blue or janus green. They have also no marked affinity for sudan dyes, and in sections prepared for the study of the mitochondria, unstained vacuoles are seen in the place of zymogen granules. The earliest secretory granules (prozymogen) are lightly stained in mitochondrial preparations ; they are larger than the granular mitochondria and are restricted to the field of the Golgi apparatus.

The mitochondria are shown most clearly in material fixed in Champy's fluid and stained with Heidenhain's iron-alum hæmatoxylin or better by treating post-osmicated material for mitochondrial staining. They are present as granules, rods and filaments scattered through the cytoplasm, especially around the nucleus (Fig. 1.5). Fasting and feeding do not induce any noticeable change in the size, shape, distribution or in the number of the mitochondria.

No evidence was obtained suggesting that the mitochondria of peptic cells change into the Golgi material, secretion granules, or that they take any part in cellular secretions as claimed by some authors. On the contrary, the location of the earliest secretory granules in the Golgi apparatus field and in intimate connexion with the Golgi substance, the difference in position between the mitochondria and secretory granules, and the changes in the morphology of the Golgi apparatus during the different phases of activity seem to point to the Golgi apparatus as being the centre of enzyme formation in peptic cells. The Golgi apparatus reticulum is argentophile and osmiophile but does not stain with sudan black, neutral red or methylene blue. The apparatus seen in living unstained or supravitally stained cells, under the phase-contrast microscope, is comparable with the Golgi apparatus picture given by silver or osmic methods.

A further account of the material is being published elsewhere.

Relationship between Blood Concentration and Environmental Salinity in *Palaemonetes varians* (Leach)

IN Britain *Palaemonetes varians*, variety *microgenitor*, commonly inhabits only saline water around the coastline and has never been recorded in fresh water. The prawn is, however, very abundant in water of extremely low salinity in the Cardiff area, where it occurs in the drainage ditches of farm-land adjacent to an area of salt-marsh[1]. In the summer months both the salt-marsh and the farm-land waterways swarm with larval prawns. The *P. varians* of these two regions are morphologically identical but differ physiologically, those from the latter habitat being in some way better suited for life in a low salinity environment. When in water of low salinity (such as that contained in the ditches traversing the cultivated area) they show a much smaller expenditure of metabolic energy (as measured by the respiratory rate) than those from the neighbouring, highly saline marsh pools[2].

Estimations of the osmotic pressure of blood taken from specimens of both habitats kept in different concentrations of sea-water have been measured by Baldes's modification of Hill's thermo-electric technique[3,4], in order to determine whether a difference in blood concentration exists in these two physiological races. A reduced blood concentration in a low-salinity medium would diminish the osmotic gradient and, as a consequence, decrease the amount of energy the animal would have to expend on osmoregulatory work.

The results are shown in Fig. 1. Both groups of prawns are isotonic at a salinity of about $20^{0}/_{00}$ sodium chloride in the external medium, which is in agreement with the figures given by Panikkar[5]. The blood concentrations vary slightly as the external medium changes in salinity; but these are comparatively minor fluctuations, being only about $5^{0}/_{00}$ sodium chloride over a range of $30^{0}/_{00}$ sodium chloride in the external environment. Both populations show a slight fall in the value for blood when the medium becomes diluted to a salinity below $10^{0}/_{00}$ sodium chloride. The small differences of values between the two sets of results are well within the range of fluctuations due to experimental error incurred by the use of this thermo-electric technique, and shows no significant difference in their concentrations. Thus the marked difference in energy consumption in media of very low salinity, displayed by these two populations of *P. varians*, is not due to one of the groups becoming subjected to a reduction in the osmotic gradient between external environment and internal body fluid. The blood concentration is the same in both cases and both are typically homoiosmotic.

A Spiral 'Valve' in the Hepatic Portal Vein

THE occurrence of laminar flow in the hepatic portal vein is acceptable on hydrodynamic grounds[1]. In any consideration of the probable distribution within the liver of blood from a particular tributary of the portal vein the anatomy of the vein is important. Drs. C. H. Barnett and W. Cochrane[2] suggest that the relative diameters of tributary and main vein and the angle of union are the important factors in determining the path of the streams. I have recently observed an anatomical structure in the portal vein which on theoretical grounds would appear to be more important than either of these factors.

In neoprene latex casts of the portal vein of rabbits there is a constant spiral groove, starting below the junction of the splenic with the mesenteric vein and ending above it, making two complete clockwise turns. In life this can be seen as a band of thickening in the vein wall, the wall bulging between the turns of the spiral. Within the vein the band of thickening corresponds to a flap or ridge projecting from the vein wall, composed of a fold in the intima and media, bridged by a continuous adventitial coat.

This structure was present in all of twelve rabbits examined. Its occurrence in other species is being investigated. Preliminary observations suggest that it is present in other small rodents but not in dogs or man.

If, as seems likely, this structure rotates the portal blood stream within the vein, then the speed of rotation will vary with flow-rate and the distribution of the different components of the portal blood to the efferent branches of the vein will vary. Since minor fluctuations in flow-rate probably occur with the respiratory changes in intra-abdominal pressure, the final result may be randomization of the distribution within the liver of the blood from any given tributary.

The presence or absence of such a spiral fold within the portal vein of any species is clearly of great importance in assessing the probability of selective distribution of the portal blood within the liver of that species.

Life-History of *Phyllodistomum simile* Nybelin

It is of interest to note that although sixty-one species of *Phyllodistomum* have been described, the life-cycles of only four have been determined experimentally and recorded. All four are American species. In Europe, however, no successful experimental work has been undertaken, although several early workers including Sinitsin[1], Reuss[2], Odhner[3], and Nybelin[4] have postulated, on the basis of morphological similarities, certain relationships between cercariæ, metacercariæ and sexually mature phyllodistomes. Many of the suggestions made in this connexion were contradictory.

The purpose of this communication is to place on record that the life-history of *P. simile*, a European species, has been elucidated by me under experimental conditions. The trematode was found in the urinary bladder of brown trout, *Salmo trutta* L., taken from the River Teify in mid-Wales. This appears to be the first record of *P. simile* in Britain. The tubular, motionless, sporocyst stages occurred in the epibranchial cavity and between the gill lamellæ of *Sphaerium corneum* L. The cercariæ are liberated from the daughter sporocysts through the birth pores and, after entering the epibranchial cavity of the clam, emerge to the outside through the exhalent siphon. The cercaria is of the macrocercous type, with a cercarial chamber in the tail, into which the body of the cercaria is completely retracted. It possesses a stylet, six pairs of penetration gland cells and a flame-cell formula of $2(4+4)+(4+4+4+4)$. There is no pharynx.

Attempts to infect aquatic insects and minnows, *Phoxinus phoxinus* L., were unsuccessful. Brown trout, *Salmo trutta* L., known to be free from infection, were, on the other hand, successfully infected in the laboratory with metacercariæ which had encysted precociously in the daughter sporocysts. Sexually mature worms were recovered three months after the initial infection. It is noteworthy that while the cercaria and certain aspects of the life-history differ from those described by the European workers, they bear many resemblances to those of the American species described by Beilfuss[5]. A detailed description of the cercaria and the life-history will be published elsewhere.

I am indebted to the Department of Scientific and Industrial Research for financial help, and also to Mr. L. E. Hughes, of the Veterinary Investigation Laboratories, Aberystwyth, for undertaking the experimental infection of the trout.

Meiosis without Chiasmata in *Periplaneta americana*

That meiosis in *Periplaneta americana* is characterized by the absence of any visible chiasma has already been reported by Morse[1] and Suomalainen[2]. However, this absence of visible chiasmata with the consequent parallel disposition of the homologues in the bivalents from the zygotene to the pro-metaphase I, in this species, differs from that in coccids[3] and dragon-flies[4], but resembles *Callimantis*[5] inasmuch as the meiosis is pre-reductional. A thorough examination of the chromosomes during the prophase of the first meiotic division reveals that this anomalous type of meiosis is closely related to the persistence of the single thread of each homologue right from the leptotene to the pro-metaphase, and it is only during the pro-metaphase stage, which is of a little longer duration than usual, that the latter is duplicated. In fact there is very little difference between the bivalents at the late zygotene and those at the early pro-metaphase, and it is the orientation of the bivalents at the metaphase plate which results in the regular segregation (pre-reduction) during anaphase of the first division. Thus, like *Callimantis*, the diplotene and diakinesis which are of practically universal occurrence in the typical pre-reduction meiosis are altogether absent in this species.

This anomaly of meiosis in *P. americana* does not, however, go in any way against the precocity theory of Darlington[6]. The homologous chromosomes in each bivalent are held together by the force of attraction due to the singleness of each homologue, even in the absence of any chiasma, throughout the prophase of the first meiotic division. The regular disposition of the bivalents at the metaphase is, however, partly due to the repulsion of the homologues, because of their duplication and partly by their orientation, which is, perhaps, accompanied by some sort of poleward pull of the homologous centromeres towards the opposite centrosomes. Unlike *Callimantis*, therefore, where according to Hughes-Schrader[5] the two pairs of chromatids show no repulsion except at the kinetochores, the repulsion of mainly the homologues, in this species, appears to play the major part in the formation of metaphase bivalents, as is evident by the ring-like configurations at this stage. The kinetochores do not appear to show any repulsion whatever, at least in some of the bivalents. In fact the homologues of each bivalent appear to be held together, at the metaphase, by the residual affinity or the terminal attraction even in the absence of any chiasma.

A detailed account of the structure and behaviour of the chromosomes in *P. americana* will shortly be published elsewhere.

Crossing-over in *Drosophila willistoni*

In the course of analysing the frequency of chromosomal inversions in 292 adult females of *Drosophila willistoni*, we have recorded for the first time evidence of crossing-over between two non-overlapping inversions in the same chromosome arm of this species. These findings are of some general interest since, as Dobzhansky and Epling[1] have said: "The biological function of inversions in natural populations of *Drosophila* and their principal role in the evolution of these insects might be conceived to be the suppression of crossing over between gene complexes which have reached an adaptive equilibrium. Crossing over would destroy these complexes and would result in gene combinations of different adaptive values, but would be prevented by the binding effect of the inversions".

In *D. pseudo-obscura* Dobzhansky and Epling found a strong suppression of crossing-over in the third chromosome due to inversion heterozygosis. Such suppression of crossing-over is adaptive, for the reasons Dobzhansky and Epling give. At the same time suppression of crossing-over reduces one source of genetic plasticity. However, there is gain in plasticity in other ways since crossing-over appears to be intensified on those chromosomes without inversions in individuals heterozygous for inversions on a given chromosome. This is true of *D. pseudo-obscura* as well as of other species[2]. In *D. willistoni* the inversions occur on all chromosomes. Suppression of crossing-over on all chromosomes would then cause a great reduction in genetic plasticity. But this does not seem to occur, as the following results indicate.

We have examined the frequency of inversion heterozygotes of six offspring of each of 292 crosses of wild virgin females with males of a strain homozygous for its gene arrangements. Table 1 shows the minimal frequency with which crossing-over occurred between inversions *B* and *J* on the third chromosome and between inversions *E* and *F* on the left arm of the second chromosome. These are minimal frequencies since not all crossing-over will be recorded in this way. There were insufficient numbers of pairs of heterozygous inversions on the other chromosomes for us to obtain estimates for these chromosomes. The flies were bred from three different wild fruits. There are no significant differences between the fruits, so the samples may be regarded as replicates. For chromosome *IIL* the minimal mean frequency of crossing-over between inversions *E* and *F* was 19·7. This is remarkably high as these two inversions are quite close to one another on the chromosome. For chromosome *III* the mean frequency of crossing-over between inversions *B* and *J* was 11·7. This is less remarkable as the distance between these two inversions is quite large, *B* being at the base of the chromosomes and *J* near the tip.

Table 1. Minimal estimates for the frequency (per cent) of crossing-over between inversions *E* and *F* in the left arm of the second chromosome and between inversions *B* and *J* in the third chromosome of *Drosophila willistoni*. Flies were bred from three different fruits

Fruit	Chromosome and inversion		No. of flies
	IIL *E* and *F*	*III* *B* and *J*	
Philodendron sp.	23	9	100
Psidium araça	20	11	100
Arecastrum romanzofianum	16	15	92
Mean	19·7	11·7	

These high frequencies of crossing-over in *D. willistoni* are quite in conformity with the principle formulated by Dobzhansky and Epling[1] to which we have already referred. It is what might be expected to happen in a species in which inversions are spread through all the chromosomes. The inversions maintain the integrity of blocks of genes within the inversions but do not inhibit recombination as between inversions.

Chromosomes of the Cultivated Mushroom

Since the original work by Maire[1], the attention of a number of cytologists[2-4] has been attracted to the study of nuclear behaviour and basidiospore formation in the two-spored cultivated mushroom, *Agaricus campestris* Fr. var. *bisporus*[5]. Sass[2] first published a full account of meiosis in the basidium, and although in one of his diagrams eight bivalents are clearly figured he reported a diploid chromosome number of approximately eight, a determination which was later confirmed[4]. In the interim, however, Colson[3], after a most comprehensive study, reported a chromosome number of $n = 9$.

The results of an investigation using a variety of mushroom grown on a commercial scale in Great Britain have proved of considerable interest, and a chromosome number differing from the two earlier recorded numbers has been found. In this material,

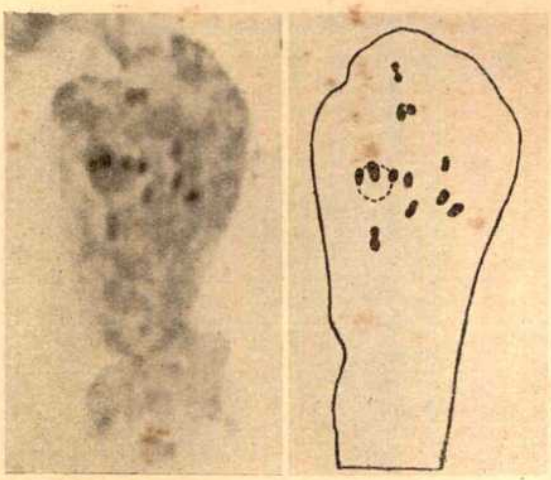

Fig. 1. Metaphase I showing twelve bivalents and a persistent nucleolus. Note the small bivalent in the 11 o'clock position (× 2,860)

twelve chromosomes have been observed at mitosis, and twelve bivalents are regularly formed at meiosis (Fig. 1). The chromosomes are extremely small and at metaphase I of meiosis the largest bivalent is slightly more than 1μ long.

Possible explanations for the reported differences in chromosome number are: (1) that different strains of the fungus having different chromosome numbers have been studied (the two haploid numbers of four were determined from American and French material, whereas the two higher counts were found in British material); or (2) that differences in chromosome number are due to limitations of technique.

In the Autobasidiomycetes, haploid chromosome numbers of $n = 4$ are most common[6], the haploid number of twelve for the mushroom being the highest reported in this group. The possibility that the variety studied is triploid has been investigated, but evidence indicative of a polyploid origin has not been found; meiotic pairing is complete and no multivalent associations have been observed.

The second possibility, that differences in chromosome number are due to inadequacy of techniques, is suggested because all earlier work was carried out using sectioned material. In the present work, considerable use was made of sectioning techniques; but it was found that reliable chromosome counts could not be obtained with such methods. The chromosomes contain considerable amounts of heterochromatin, and in many of the preparations studied there was a tendency for secondary association of bivalents. Associations of bivalent chromosomes are difficult to resolve in sectioned material, and consistently accurate counts were only achieved through the use of squash techniques. For this purpose, material was fixed in a mixture of chloroform, ethanol and glacial acetic acid (7 : 5 : 2) and stained in aceto-carmine or acetic orcein.

Although the possibility of the existence of different chromosome races cannot be ruled out, the minuteness of the chromosomes, together with the inadequacy of sectioning methods for accurate chromosome analysis, lend support to the suggestion that previous counts may have erred on the low side.

This work was conducted in the Department of Agricultural Botany, Aberystwyth, under the direction of Prof. P. T. Thomas, whose help and encouragement are gratefully acknowledged: a more detailed account will be published later.

Dormancy of Seeds of *Phalaris arundinacea* and *Phalaris tuberosa*

DORMANCY, giving rise to irregular and poor germination, is a characteristic of certain strains of *Phalaris arundinacea* and *P. tuberosa*.

Seeds of the Welsh Plant Breeding Station strain *S*.230, a hexaploid hybrid derived from *P. tuberosa* × *P. arundinacea*, were subjected to thirteen treatments, as in Table 1, and incubated on a Jacobsen apparatus at 25° C. with access to light. Seeds of a commercial strain of *Lolium perenne* were used as a check.

The treatments involving dehulling, scarifying and pricking show a significant increase in germination compared with the control. The causal factor of dormancy remains unknown; but the following points are indicative: (1) The caryopses swell, therefore water is not limiting. (2) Pricking the palea with a pin and scarifying are partially effective, therefore a chemical inhibitor within the palea is unlikely, and this is borne out by the ineffectiveness of the soil and water treatments designed to reduce the concentration of a possible inhibitor. (3) Pricking can be effective, so mechanical impedance of the coleorhiza by the palea is unlikely, particularly as seeds dehulled after twenty-one days incubation showed no signs of rupture of the integument. (4) Treatments designed to remove epidermal secretions of wax, fat, etc., failed to have any significant effect on germination, though possibly they were not sufficiently drastic. (5) After twenty-one days incubation the palea were removed from a number of seeds within each treatment which had failed to germinate, and within 48 hr. a high percentage (30–100 per cent) had emerged.

Table 1. THE GERMINATION PERCENTAGE OF *S*.230 WHEN SUBJECTED TO VARIOUS TREATMENTS

Time / Treatment	No. of days				
	3	5	7	14	21
Acetone for 15 sec.	0	0·41	0·41	0·82	1·23
Acetone for 3 min.	0	0·79	0·79	1·2	1·2
50° C. water for 5 min.	0	0	2·9	3·9	4·5
50° C. water for 20 min.	0	0	1·6	2·8	3·6
4*N* sulphuric acid for 60 sec.	0	0·4	1·2	2·2	3·2
Ether for 15 sec.	0	2·2	2·4	4·4	5·2
70 per cent ethyl alcohol for 15 sec.	0	0·4	1·6	2·6	2·8
Germinated in 4 mm. deep tap water	0	0·4	1·2	1·4	1·6
Germinated on moist garden soil	0	0	1·2	1·2	3·6
Germinated on washed soil	0	0	1·2	2·4	2·8
Pricked with a pin	11·1	19·7	26·7	32·7	37·4
Scarified with sand paper	14·8	35·4	42·5	48·3	50·9
Dehulled	41·9	63·4	70·9	73·1	73·1
Control	0	1·2	2·8	3·4	4·8
Commercial *Lolium perenne*	36·3	84·8	88·8	90·8	90·8

A gaseous inhibitor is not inconsistent with the above facts, and it is suggested that failure to germinate is due either to a lack of oxygen, or to a build-up of carbon dioxide concentration having a narcotic effect, within the immediate region of the germinating embryo.

A more detailed report of this and other experiments will appear elsewhere.

Differences in Social Aggregation in Two Species of Locust

Natural populations of locusts are characterized by large fluctuations in numbers, accompanied by changes in morphology, colour and behaviour in both the nymphs (hoppers) and the adults. When numbers are high, the hoppers aggregate into bands containing from a few hundred to several thousand individuals. Similar gregarious hoppers can be produced in the laboratory by rearing several together in one cage[1]. There is much circumstantial evidence to suggest that, provided the total numbers are sufficient, the formation of hopper bands depends partly on a patchy physical environment, especially a vegetation mosaic, and partly on strong attractions between hoppers[2,3].

In the laboratory, the hopper inter-attractions leading to aggregation have been studied in cages that provide a physically uniform environment[4]. In recent experiments, groups of ten hoppers were tested in an evenly lighted and heated, ring-shaped cage, the floor of which was marked radially into twenty equal divisions. When first placed in the cage, the ten hoppers moved about; but later they settled down, those in the same division generally touching one another. After 30 min. the number in each division was noted. The hoppers were then disturbed so that the groups were broken up, and after another 30-min. period the number in each division was again noted. Four such readings constituted a test. No hopper group was subjected to more than one test per day.

If the hoppers settled at random, the number of cage divisions containing 0, 1, 2, 3, and so on, would follow a binomial distribution given by the formula $(19/20 \times 1/20)^{10}$. The percentage of hoppers grouped (that is, in groups of two or more) would be 37·5, and in each test of four readings, involving 80 divisions, 48 divisions would be empty, 25 would contain one hopper and 7 would contain two or more. If more hoppers were grouped than one would expect for random distribution, then the grouping was due to the hoppers being attracted to one another, since the cage provided a physically uniform environment and the hoppers moved actively before coming to rest. Such grouping has been called social aggregation[4]. In successive tests, any differences in the amount of grouping was a measure of the difference in strength of hopper inter-attractions.

Two locust species, *Locusta migratoria migratorioides* (R. and F.) and *Schistocerca gregaria* (Forsk.), were compared. They came from the routine stocks of the Anti-Locust Research Centre that have been kept crowded in cages for many generations. Small batches of hoppers (six batches of *Locusta* and seven of *Schistocerca*) were tested soon after hatching and at intervals of one or two days afterwards until the end of the first instar. The tests were carried out at an air temperature of 28° C. and the hoppers were well fed before each test, these physical conditions having been found to be optimal for social aggregation in both species[4,5].

Table 1. The Average Number of Divisions containing 0, 1, 2, 3 or more Hoppers

(The figures are based on 3–5 separate tests, each test consisting of four readings)

Age from hatching	*Locusta*					*Schistocerca*				
	No. of hoppers per division				P*	No. of hoppers per division				P*
	0	1	2	3 or more		0	1	2	3 or more	
Up to 3 hr.	47	27	5	1	>0·8	52	21	4	3	>0·5
6–12 hr.	53	19	6	2	>0·3	55	15	6	4	<0·05
1 day	52	20	6	2	>0·3	58	13	4	5	<0·02
2 days	55	16	4	5	>0·05	58	12	6	4	<0·01
3 days	58	12	5	5	<0·01	59	13	2	6	<0·02
4 days	58	13	5	4	<0·02	58	13	4	5	<0·02
5 days (near to moulting)	55	15	6	4	<0·05	55	15	6	4	<0·05

* Probability of distribution being random

Soon after hatching and the intermediate moult, when the cuticle was still a little soft, the hoppers of both species distributed themselves at random within the cage (Table 1). About six hours after hatching, the *Schistocerca* hoppers showed strong attractions for one another and their distribution was probably not a chance one. One day after hatching, *Schistocerca* showed maximum social aggregation and the hopper distribution differed significantly from chance. This contrasted strongly with the behaviour of the *Locusta* hoppers, which continued to settle at random until they were two or three days old, maximum aggregation not occurring until they were three or more days old.

The hatching of hoppers of swarming populations of *Schistocerca* has often been observed in the field. The hoppers of each egg pod usually hatch within a few minutes of one another[2] and the number from a single pod is generally between 40 and 90. Consequently, the hoppers begin their life by being grouped. For the first five or six hours after hatching they are very inactive and remain grouped around the egg-pod holes. If they are undisturbed, very little movement takes place during the first day. The laboratory experiments suggest that one day of grouping is sufficient for the hoppers to learn to aggregate and so to resist factors leading to dispersal. No corresponding field observations have yet been made with hatchlings of swarming populations of *Locusta*, but the specific difference in social aggregation demonstrated in the laboratory suggests that under natural conditions hatchlings of *Locusta* are more easily dispersed than those of *Schistocerca*. It also seems likely that a patchy physical environment is of greater importance in the retention of groups and the formation of new ones in *Locusta* than in *Schistocerca*.

I wish to thank Prof. G. C. Varley for laboratory facilities in the Hope Department, Oxford.

"Lucubratory Biochemistry"

Under this title a review of my biochemistry text-book was published in *Nature* of March 24, p. 544. The reviewer criticizes many of my statements by expressions such as "astonishing dictum", "Paradox indeed", or by other ironical remarks. A reply to each of the numerous comments would occupy much space. Therefore, only a few of them can be answered here.

The reviewer quotes as "interesting" the statement that natural isotopes are stable, and asks: "Has Dr. Haurowitz never heard of naturally occurring radioactive isotopes, for example of potassium or of carbon ?" It is not evident from the review that the statement criticized is made in a section on "Methods", in which only those isotopes are treated which are used as tracers in biochemical research. Obviously, the statement on the stability of natural isotopes applies only to isotopes of this type. Natural radioactive potassium and carbon, mentioned in the question of the reviewer, are not used as tracers. Potassium-42 and carbon-14, used in tracer work, are produced artificially. The obvious answer to the first part of the question asked by the reviewer is that every high-school boy knows about the occurrence of uranium and of other radioactive isotopes in Nature. One may wonder why the question was asked.

The review contains the following comment: "On p. 132 the statement is made, 'The amino acids are colorless substances that are soluble in water', although later the insolubility of cystine in water is mentioned (p. 156)". On p. 156 I wrote: "Cystine, in contrast to cysteine, is almost insoluble in water". Omission of the word "almost" creates here a contradiction.

Another comment refers to the following words of my book: "Attempts to prepare estrogenic hormones synthetically, led to the unexpected result that certain *stilbene derivatives*, such as dihydroxydiethylstilbene, are just as active as estradiol". This statement is criticized as "historically incorrect, as can be seen by consulting the early papers of Dodds and his collaborators". Dodds and his co-workers, in their paper on the œstrogenic activity of stilbene derivatives (*Proc. Roy. Soc.*, 127, p. 140), wrote: ". . . in view of the difficulties presented by the total synthesis of the naturally occurring œstrogenic hormones, attempts were made to prepare more accessible substances the molecules of which would be similar to œstradiol in shape, weight and in the situation of the hydroxyl groups". Readers of *Nature* will now be able to judge whether my presentation was "historically incorrect".

More than a dozen examples of a similar type could be added. They would not show more than the three examples given above, namely, that most of the comments of the reviewer are hypercritical and that the text of my book is not so inadequate as it may appear to those who read only the review in *Nature*.

Felix Haurowitz

Department of Chemistry,
Indiana University,
Bloomington, Indiana.
Aug. 5.

Since my review was critical, I attempted to be as fair as possible by quoting at length some of the extracts with which I did not agree. I do not believe that any useful purpose can be served by arguing about individual points, although I could take up each of the comments which Prof. Haurowitz has made. I am content to leave those who wish to judge whether my review was fair or not to read it in relation to the book itself.

University of Cambridge.

A Word Common to the Natives of Alaska, Canada, Greenland and Brazil

Dr. Nicholas Polunin has suggested that I should direct the attention of botanists and others to the ancient provenance of a word which appears to mean fundamentally 'the juice of a plant that is used for chewing', as a chewing gum.

Not being English or French, but of speech a mid-west American from Manitoba and Dakota, it did not mean anything to me when in 1906 I heard the Eskimos of the Mackenzie Delta and north-eastern Alaska speaking of spruce gum as 'kutsuk'. They used to fetch this themselves from the evergreen forest to the south or buy it from the forest Indians; more recently, they had been buying flavoured chewing gum from the whalers, which they also spoke of as 'kutsuk', as they did of a substitute of their own, dried seal blood, which they said they "always" used in the pre-white days if they ran out of spruce gum for their children to chew.

Years later, perhaps in 1912, I learned that the word for the gum of a Brazilian plant, and of other South American plants, is 'caoutchouc', and the Oxford Dictionary defines it as "a milky resinous juice of certain trees in S. America . . .". The Oxford Dictionary goes on to connect the derivation of this word for rubber with a French expedition to the Amazon country in 1739. 'Webster' has the same tale, more briefly, and gives varied spellings, among them 'caucho' and 'gutteux'. I like the last best, for it is nearest to what I have heard among the Eskimos from Bering Strait to Coronation Gulf. They said 'gutsuk', the *s* as always in their tongue with an *sh-* sound.

Turning now to Greenland, in Sam. Kleinschmidt: "Den Grønlandske Ordbog" (Copenhagen, 1871), I find "kutsuk. (1) Harpix (det almindelege, af Naaletraeer; (2) hvad der paa samme Maade udsondrer sig i andre Traeer: Gummi, Campher og lignende producter". Schultz-Lorentsen's "Dictionary of the West Greenland Eskimo Language" (Copenhagen, 1927) has only: "kutsuk, resin, gum".

So we appear to have in the New World a term for the gum of a plant which people use for chewing and call by the same name from Greenland to Alaska to Brazil. When I first began to talk about this, I was told it was coincidence. But the intellectual climate is changing, among other things in linguistics, and now the disciples of men like Uhlenbeck and Hammerich think 'connexion' a likelier word than 'coincidence'. Incidentally, I found the Eskimos saying 'ignirk' for fire and I knew that the Romans said 'ignis'; but again my linguist friends said 'coincidence'; now I believe the followers of Uhlenbeck think we have in this a connexion from the Sanskrit to the Latin to the Eskimo.

Institution of Chemical Engineers (at the Royal Institution, Albemarle Street, London, W.1), at 3 p m.—Symposium on "Grinding".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p m —Symposium on "The Spectral Approach to Time Series". Papers by Mr. A. M. Walker, Mr. S. K. Zaremba and Mr. Z. A. Lomnicki and Dr. P. Whittle.

Society for Analytical Chemistry (in the Meeting Room of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p m.—Dr. H. M. N. H. Irving: "The Structure of Dithizone and its Metal Complexes".

Thursday, November 8

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. M. Blackman and Mr. N. D. Lisgarten: "The Cubic and other Structural Forms of Ice at Low Temperature and Pressure"; Mr. J. F. Nye: "The Distribution of Stress and Velocity in Glaciers and Ice Sheets".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J Eccles: Lecture on the Visit of the British Electricity Supply Delegation to the Soviet Union.

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S.W 1), at 6 p.m —Mr. D. C. Broome and Mr. A. Please: "The Use of Mechanical Tests in the Design of Bituminous Road Surfacing Mixtures, Part 2—Stability Tests on Rolled Asphalt".

Institution of Mechanical Engineers, Lubrication and Education Groups (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "The Extent to which Lubrication should enter into First Degree and H.N.C Courses".

Royal Institute of Chemistry (joint meeting with the Acton Technical College Scientific Society, at Acton Technical College, High Street, Acton, London, W.3), at 7 p m.—Prof. M. J. S. Dewar: Some Aspects of Modern Theoretical Chemistry".

Friday, November 9

Institution of Mechanical Engineers, Hydraulics Group (at Birdcage Walk, Westminster, London, S.W 1), at 6 p.m —Mr. [illegible] H. Lever, Dr H. Ritter, Mr. M. Woolfson and Mr. C. T. Wright: Rotating Beam Channel and 30-in. Water Tunnel at the Admiralty Research Laboratory".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at .30 p.m.—Mr. A Renfrew: "Plastics in Perspective".* (Fifth of en University Extension Lectures on "Technology and Industry". Further lectures on November 16, 23, 30, December 7 and 14.)

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Dr. F. Sanger . "The Chemistry of Insulin".

Royal Institution (at 21 Albermarle Street, London, W.1), at p.m.—Prof. Sir Charles Dodds, F.R.S. . "The Chemical Substances influencing Mental and Physical Development".

Friday, November 9—Saturday, November 10

British Society for Immunology (at the Wellcome Foundation, 183 Euston Road, London. N.W.1), at 10 a.m.—Scientific Papers. Friday afternoon—Symposium on "Complement".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Biologist (with a degree in biochemistry or physiology) to the Hospital and Medical School—The Secretary, King's College Hospital Medical School, Denmark Hill, London, S.E.5 (November 9).

Assistant, Grade B, in Physics—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (November 10).

Scientist (with a good degree (preferably in chemistry) or equivalent qualification, and preferably previous editorial experience), for duties which include the progressing of research programmes, editing research reports, etc.—The National Coal Board, Coal Research Establishment, Stoke Orchard, near Cheltenham, Glos, quoting X.450 (November 12).

Pasture Research Officers (3) (either with a degree in the natural sciences, with botany as a major subject, and postgraduate training in ecology and pasture research, or a degree in agriculture with training in pasture research, and preferably with experience in the establishment and management of pastures and in the management of dairy cattle and sheep) in the Department of Research and Specialist Services, Federal Ministry of Agriculture, Federation of Rhodesia and Nyasaland—The Public Service Attaché, Rhodesia House, 429 Strand, London, W.C.2 (November 15).

Hospital Biochemist, Senior or Principal Grade (with a university degree in science or equivalent qualification, and preferably with a higher qualification or good research experience), in the routine Biochemical Laboratory—The House Governor and Secretary, Royal Victoria Infirmary, Newcastle-upon-Tyne 1 (November 17).

Lecturer in Psychology in St. Salvator's College—Joint Clerk to the University Court, College Gate, St. Andrews (November 17).

Physical Chemists and Chemical Engineers (with a good honours degree or equivalent, and preferably experience), for important technical research into developing new processes for making smokeless fuels—The National Coal Board, Coal Research Establishment, Stoke Orchard, near Cheltenham, Glos, marking envelope "X/447" (November 19).

Assistant Lecturer in Zoology—The Secretary, The Queen's University, Belfast (November 20).

Senior Lecturer, Lecturer or Assistant Lecturer in Botany at the University, Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 20).

Lecturer (British subject, with a first- or second-class honours degree in mathematics, and preferably teaching experience) in the Department of Mathematics—The Director of Studies, Royal Naval College, Greenwich, London, S.E.10 (November 24).

Lecturer (with special qualifications in palæontology) in Geology—The Registrar, King's College, Strand, London, W.C.2 (November 24).

Assistant in Inorganic or Physical Chemistry—Joint Clerk to the University Court, Queen's College, Dundee (November 30).

Chair of Geology in the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 30).

Lecturer or Assistant Lecturer in Mathematics at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 30).

Lecturer (with a degree or diploma and preferably research, teaching and industrial experience) in General Chemistry for Engineering Students in the School of Applied Chemistry, New South Wales University of Technology, Sydney, Australia—The Agent-General for New South Wales, 56 Strand, London, W.C.2 (Australia, November 30).

University Lecturer in Mathematics—The Secretary, Appointments Committee of the Faculty of Mathematics, The Arts School, Bene't Street, Cambridge (November 30).

X-Ray Crystallographer (preferably with some experience of powder methods and work on metals), for special investigation sponsored by the Central Electricity Authority—The Secretary, Birkbeck College (University of London), Malet Street, London, W C.1 (December 1).

Chair of Chemistry—The Secretary and Registrar, The University, Southampton (December 15).

Senior Physicist (with a B.Sc. degree, preferably with honours in physics, and an extensive knowledge of electronics) with the Auckland Hospital Board, New Zealand, for duties which include responsibility for a 4 MeV. linear accelerator—Office of the High Commissioner for New Zealand, 415 Strand, London, W.C.2 (New Zealand, December 31).

Biologist (with a biological degree with emphasis on botanical and biochemical subjects) to carry out an investigation into the nature of the food of British wildfowl and into the nutritional requirements of wildfowl in captivity—The Assistant Director (Research), The Wildfowl Trust, Slimbridge, Gloucestershire.

Chemist (with an honours degree or A.R.I.C. or F R.I.C., and at least three years post-qualification experience) in the Medical Department, Government of Hong Kong—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.117/51/018.

Engineer or Physicist (young graduate, preferably with some mathematical ability and experience in the use of electronic instruments) at Sheffield, for work on the problems of file testing and manufacture—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W 1, quoting "F 2".

Experimental Officer/Assistant Experimental Officer (with at least H.N.C. chemistry or equivalent), to assist in fundamental and applied investigations relating to radioisotopes and surfaces—The

Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. A 1154/34.

EXPERIMENTAL OFFICER (at least 26 years of age, with higher school certificate, or equivalent qualification, in science subjects) WITH THE TECHNOLOGICAL IRRADIATION GROUP of the Isotope Division, to be responsible for the operation of a number of kilocurie radiation sources, and projects associated with the investigation of the effects of radiation on chemical reactions, foods and other materials—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting 661/34

LABORATORY TECHNICIAN (qualified in biochemistry or chemical pathology) IN THE DEPARTMENT OF CHEMICAL PATHOLOGY—The Finance Officer, St. Thomas's Hospital Medical School, London, S.E.1.

METEOROLOGIST (well qualified and experienced) with the Government of Cyprus, to investigate meteorological stations and the needs of technical departments concerned for climatological research; to advise on measures needed for reorganization, and to train a suitable Cypriot officer as his successor—The Director of Recruitment, Colonial Office, London, S W.1, quoting BCD.57/17/01.

PHYSICIST/CHEMIST (male or female, M.Sc. or B.Sc. (Hons.) with majors in chemistry and physics, and a knowledge of microscopy) IN THE MINES DEPARTMENT, Government of Northern Rhodesia, to undertake research into the problems of silicosis, particularly in connexion with analysis of mine-dust samples by X-ray diffraction and by chemical methods, and to set up and equip a laboratory at the Headquarters of the Mines Department in Northern Nigeria—The Director of Recruitment, Colonial Office, London, S W.1, quoting BCD.99/3/04.

RESEARCH FELLOW (with a degree in either physics, chemistry or metallurgy) IN THE FIELD OF THE VISCOSITY OF MOLTEN METALS—The Department of Industrial Metallurgy, The University, Edgbaston, Birmingham 15.

SCIENCE GRADUATE (preferably with experience in clinical biochemistry), to work on metabolic studies at the Institute of Orthopædics, Royal National Orthopædic Hospital, Stanmore, Middlesex—The Dean, Institute of Orthopædics, 234 Great Portland Street, London, W 1.

SCIENTIFIC OFFICER (with a good honours degree and an interest in biological problems, and preferably some research experience) IN THE CHEMISTRY DEPARTMENT to take part initially in researches on the chemistry of the milk proteins and enzymes—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 56/12.

SENIOR LECTURER or LECTURER IN MATHEMATICS; SENIOR LECTURERS or LECTURERS IN RADAR AND TELECOMMUNICATIONS; and a SENIOR LECTURER or LECTURER IN ENGINEERING PHYSICS at the Royal Military College of Science, Shrivenham—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.361/6A.

SENIOR LECTURER (with a higher degree or considerable practical or research experience) IN CIVIL ENGINEERING with either hydraulics, hydrology or public health engineering—The Secretary, Royal College of Science and Technology, Glasgow, C.1.

SOIL ANALYST (with a good honours degree in chemistry and not less than three years postgraduate experience in soil or agricultural chemistry) IN THE DEPARTMENT OF SOIL AND LAND-USE SURVEY, Gold Coast Local Civil Service, to supervise routine analysis of soil samples, to carry out special soil analysis and laboratory investigations relating particularly to the nutrient status of soils used for cocoa production, and to undertake the training of junior analytical assistants—The Director of Recruitment, Colonial Office, London, S.W 1, quoting BCD.79/13/06.

SOIL SCIENTIST (with an honours degree in natural science, chemistry and/or botany) in Gambia (H.M. Oversea Civil Service), to undertake research into soil deficiencies—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/12/010.

TECHNICIAN (male or female, preferably with research experience) IN THE DEPARTMENT OF PHARMACOLOGY—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

ZOOLOGIST (with a good honours degree in zoology and preferably the ability to pilot light aircraft) to assist in the study of the populations and ecology of wildfowl—The Assistant Director (Research), The Wildfowl Trust, Slimbridge, Gloucestershire.

LECTURES AND COURSES

UNIVERSITY OF BIRMINGHAM

A summer course on "Oilfield Reservoir Engineering" will be held in the University of Birmingham during July 1-26, 1957. The course, which will be residential, will comprise lectures by members of the Petroleum Production Department of the university and specialist lectures from industry, including, in particular, the British Petroleum Company Limited.

Further information can be obtained from H. Gilmour, Petroleum Production Department, University, Edgbaston, Birmingham, 15.

G L. BARNES,
Secretary.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

LONDON, S W.7

TECHNICAL OPTICS SECTION

A course of six lectures on "Microwave Optics" will be given by Dr. J Brown (University College, London) on Tuesdays and Thursdays at 4.30 p m., commencing Tuesday, November 27, 1956, but omitting November 29. The lectures will be held in the Physics Department, Royal College of Science, Imperial Institute Road, South Kensington. The fee for the course is £2 2s Students of the College and Inter-Collegiate students will be admitted free.

Copies of the syllabus and application forms may be obtained from the Registrar of the Imperial College, Prince Consort Road, S.W.7.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

(TECHNICAL OPTICS DEPARTMENT)

A Course of eight lectures
on
MICROSCOPY
will be given on

Tuesdays and Thursdays at 4 p.m., commencing Tuesday, January 29, 1957.

A course of practical work will also be given from February 25 to March 22, 1957. This will consist of 8 periods of 3 hours each.

Application for admission should be made to the Registrar of the Imperial College, Prince Consort Road, London, S.W.7.

The fee is two guineas for the lectures, and four guineas for the practical work.

UNIVERSITY COLLEGE LONDON

FREE PUBLIC LECTURES, AUTUMN TERM, 1956

Thursdays, November 15, 22, at 5 p m; Dr. Dorothy Needham, "The Biochemistry of Muscular Action."

Thursday, November 29, at 5 p m, Professor G. F. Marrian, "Some Recent Progress in the Biochemistry of the Oestrogenic Hormones."

Complete list of public lectures (including lunch-hour lectures), from Publications Officer, University College, Gower Street, W.C 1. (Stamped addressed envelope required.)

THE POLYTECHNIC

REGENT STREET, W 1

DEPARTMENT OF CHEMISTRY AND BIOLOGY

Six lectures on "Ionic Reactions in Organic Chemistry" will be given on Friday evenings at 7 p.m. commencing November 2, 1956.

Lecturers: Professors E. D. Hughes, C A Vernon, Drs. V. Gold, P. B. D. de la Mare, W Davey, R. J. Gillespie.

Fee for the course: 11s.

Enrolment forms may be obtained on application to the Director of Education.

OFFICIAL APPOINTMENTS

AUDIO-VISUAL AIDS OFFICER

Applications for the above appointment for an initial term of three years are invited from suitably qualified and experienced persons. The appointee will be required to live in Sydney, Australia, but must be prepared to travel on duty within the South Pacific area in order to promote the development of the audio-visual aids project. Initial salary in range £stg.1,000 to £stg.1,300, plus special allowances.

For further particulars, including outline of duties and details of allowances, apply by airmail to South Pacific Commission, Box 5254, G.P.O., Sydney, Australia.

Applications should be sent by airmail to Secretary-General, South Pacific Commission, Noumea, New Caledonia, and postmarked not later than December 15, 1956.

TOBACCO RESEARCH BOARD OF RHODESIA AND NYASALAND

APPOINTMENT OF BIOCHEMIST

The appointment of Biochemist to the Board is open to applicants with suitable training and experience in biochemical work Physiology training will be considered an advantage. Investigational work would include biochemical, chemical and physical analyses of tobacco from fertilizer, rotation, variety, breeding and other experiments now in progress at the Board's Headquarters in the Federation. Commencing salary would be at the rate of £2,050 per annum, any higher offer being subject to negotiation dependent on qualifications and experience.

Application, nominating two referees, should be made in the first instance to the Director, Tobacco Research Board of Rhodesia and Nyasaland. P O. Box 1909, Salisbury, Southern Rhodesia, by November 30, 1956. Consequent on the initial consideration of applicants, further information would be forwarded concerning conditions of service, etc.

PHYSICIST

(SENIOR GRADE)

Applications, with the names of two referees, are invited for the above post in the Radiotherapy Department, Charing Cross Hospital, London, W C 2 Hospital experience is not essential but a knowledge of X-rays, radium and radioactive isotopes is required. Duties concern routine Radiotherapy Physics, and the applications o' radioactive substances in other branches of medicine Salary scale £950 per annum to £1,280 per annum.

FRANK HART,
Secretary to the Board of Governors.

THE WILDFOWL TRUST WISHES TO RECRUIT a Zoologist to assist in its expanding study of the populations and ecology of wildfowl. A good degree in zoology is required and, as emphasis will be laid on the application of aerial survey and aerial photography to wildfowl censuses, the ability to pilot light aircraft would be most desirable. The appointment will be for three years in the first instance, in the salary range £655 by £30 to £715, with good prospects of a more permanent establishment.—Applications to The Assistant Director (Research), The Wildfowl Trust, Slimbridge, Gloucestershire.

SCIENTIFIC OFFICERS

required by

THE ATOMIC WEAPONS RESEARCH ESTABLISHMENT, ALDERMASTON, BERKS

Candidates for all posts should possess a first- or second-class honours degree and preferably have had research experience in an appropriate subject.

Ref. 1305/34. To carry out basic research on the alloying behaviour of radioactive metals.

Ref. 1306/34. To carry out basic research on the basic properties of radioactive metals.

Ref. 1307/34. To investigate methods of preparation and properties of thin metallic films. Practical experience of one of the following would be an advantage: Vacuum technology, metallography, electron diffraction, vacuum evaporation of metals and cathodic sputtering.

Ref. 1308/34. Physical chemist for research into certain problems in the fields of corrosion connected with the design of reactors.

Ref. 1309/34. For research and development work on electro deposition of metals This post will be graded either Senior Scientific Officer or Scientific Officer.

Salary. Senior Scientific Officer, £1,155 to £1,355 per annum. Scientific Officer to be assessed according to age, qualifications and experience within the scale of £615 to £1,065 per annum. Contributory Superannuation Scheme. A house or assistance towards legal expenses on house purchase will be available for married officers living beyond daily travelling distance.

Requests for application forms, by postcard, to Senior Recruitment Officer at the above address. Please quote the appropriate reference.

LIVERPOOL RADIUM INSTITU MANAGEMENT COMMITTEE

1, MYRTLE STREET, LIVERPOOL, 7

Applications are invited for the post of chemist (Senior Grade) in the Pathological partment of the Institute. First- or second- honours degree essential. The appointment cludes both routine hospital biochemistry work connected with the investigations into uses of radioactive isotopes in medicine. A opportunity and facilities are available for of a research nature into the problems of biochemistry of neoplastic disease. Salary conditions of service in accordance with recommendations of the Whitley Council.

Applications, stating age, qualifications and perience, together with the names and addr of two referees, to reach the Secretary by No ber 17, 1956.

UNIVERSITY OF TASMANIA

AUSTRALIA

Applications are invited for the following pointments: Lectureship in Geography. P ence will be given to candidates with special fications and experience in human geogr Lecturer in Psychology. Candidates should an honours degree or higher in psycho Special consideration will be given to appl with qualifications in child or developm and/or abnormal psychology. The salary s are: Lecturer, £A 1,500 to £A.1,750; Senior turer, £A.1,850 to £A.2,150, with annual ments of £A 50. An appointment will be of at a commencing salary commensurate wit qualifications and experience of the perso whom an offer is made, in each case. An a ance is made towards travelling expenses.

Further particulars and information as t method of application may be obtained from Secretary, Association of Universities of British Commonwealth, 36 Gordon Sq London, W.C.1. The closing date for the r of applications, in Australia and Londo December 15, 1956.

MAKERERE COLLEGE

THE UNIVERSITY COLLEGE OF EAST AFRICA

Applications are invited for Lectureship in cultural Zoology Salary scale: £1,107 by £ £1,149 by £45 to £1,284 by £51 to £1,335 b to £1,389 by £57 to £1,617 per annum. allowance £50 per annum per child (max £150 per annum). Free passages for memb staff and family (up to four adult passages) o pointment, termination, and leave (three m every 21 months). Rent according to qu provided, £45 to £84 per annum (including furniture.)

Detailed applications (six copies), naming referees, by November 30, 1956, to Secr Inter-University Council for Higher Edu Overseas, 29 Woburn Square, London, W from whom further particulars may be obt

PRINCIPAL/SENIOR SCIENTIFIC OFF required by the Atomic Weapons Res Establishment, Aldermaston, Berks. To ass the direction and carrying out of research variety of projects. Fields of particular in are the physical chemistry of organic an organic phosphors and chemical studies relat reactors. The post offers wide scope for cants primarily interested in research. Appl should hold a first- or second-class honour gree in physical or inorganic chemistry and s be experienced physical chemists with a s interest in thermodynamics. Salary: Pri Scientific Officer, £1,390 to £1,980 per an Senior Scientific Officer, £1,155 to £1,35 annum. Contributory Superannuation Schem house or assistance towards legal expense house purchase will be available for m officers living beyond daily travelling dista Requests for application forms, by postcar the Senior Recruitment Officer at the abov dress. Please quote Ref. 1311/34

CURATOR/TECHNICIAN REQUIRED the Department of Geology at the Univ College of Swansea for a period of one ye the first instance. Commencing salary be £380 and £455 per annum according to qua tions and experience. Applicants must be 21 years of age, and have had a sound g education. Preference will be given to appl having special interests in palaeontology though previous experience is not ess Duties will include the care and cataloguі geological laboratory and museum specimen collections.—Applications (with copies of monials), should be forwarded without del the Registrar, University College, Singleton Swansea.

Two important new books from

PERGAMON PRESS

The Airglow and the Aurorae

Proceedings of a symposium held at Queen's University, Belfast, on September 6th and 7th, 1955.

Edited by A. Dalgarno and E. B. Armstrong

This volume consists of a collection of 53 papers and is international in character. It includes contributions from Great Britain, France, U.S.A., Germany, Belgium, Canada, Norway, Japan, and in particular there are seven contributions from Russia presented in English. It collects together papers from workers in all those various fields of research which find application to the understanding of the airglow and aurorae. In view of the imminence of the International Geophysical Year, this book would appear timely in pointing to the gaps in our knowledge of the subject.

Over 400 pages. Profusely illustrated.
£7 10 net ($22.50)

Solar Eclipses and the Ionosphere

Proceedings of a symposium sponsored by I.C.S.U. Mixed Commission on the Ionosphere at the Royal Society, Burlington House, London, August 22nd–24th, 1955.

Edited by W. J. G. Beynon and G. M. Brown

This book contains about 50 papers and presents in one volume as full an account as possible of the various aspects of the influence of solar eclipses on ionospheric phenomena. It provides a complete and up-to-date survey of the present position in this field of research . . . includes an exhaustive bibliography of literature on solar eclipses and the ionosphere, arranged chronologically.

Approx. 350 pages. Illustrated.
£7 ($21)

GOVERNMENT ORGANIZATION OF RESEARCH

IN view of the attempts which are frequently made to compare both the magnitude and the organizaion of the research effort in Great Britain with that in the United States, the report "Organization of the Federal Government for Scientific Activities" which has recently been issued by the National Science Foundation in its National Science Studies series is of considerable interest*. It is one of a series of publications which set forth the basic facts concerning he scientific research effort of the United States, and is the outcome of a study made by the National Science Foundation in 1954 and 1955. It covers not only the conduct of research and development but also their planning and administration and the expansion of facilities for this purpose, the training of scientific man-power and the dissemination of cientific information, as well as the collection of tatistics in the natural and social sciences and such matters as testing, evaluation and standardization.

The report is in two parts, the first being a direct sequence to the Steelman Report of 1947, and giving pecial attention to subsequent developments. The econd, which occupies more than three hundred of he 340 pages, describes the organization for scientific activities of each department and agency of the Federal Government. It does not attempt to give more than a summary of the scientific effort of the Government as a whole, though the nature of the scientific programme of the thirty-eight departments and agencies is briefly indicated.

This second part of the report should serve as a reference work on the scientific activities of the Federal Government, to which there is nothing parallel in Great Britain either in scope or scale. Thus in Britain the account of "Government Scientific Organization in the Civilian Field" which the Advisory Council on Scientific Policy produced in uly 1951 does not deal with the defence departments, nor does it indicate the man-power employed by the various departments and agencies on scientific ctivities, excluding grants to the universities through the Universities Grants Committee. Without fuller nowledge of the man-power and resources involved —as is provided in the American report for the United States—effective discussion of the scale and irection of the scientific effort of Britain is hamstrung, as was evident in the recent discussions on the Department of Scientific and Industrial Research Bill. Mr. James Callaghan, for example, in urging n July 16 in the House of Commons the need for more effective co-ordination in research, particularly between the Service Departments and the Civil Departments, put the present expenditure on research at £235 million, of which the Department of Scientific and Industrial Research was responsible only for some £10 million. He could, however, only add that, or the rest, the great bulk of the expenditure was n the research side.

The National Science Foundation does not in this report give the total Federal expenditure on research, though it points out that in 1954 defence research accounted for 86 per cent of the Federal expenditure on research, as compared with an estimated 20 per cent in 1938. Figures given in the report put the total expenditure on defence at little short of 19,000 million dollars out of 23,500 million and the scientific staff at some 23,000, of whom all but 191 are in one or other of the three Services, out of a total of 45,000 scientists in Government service. The analysis is made by departments and agencies but gives the expenditure and personnel devoted to scientific activities as compared with that devoted to the total activities of the department or agency and not necessarily that given to research alone. Even so, we are left with a much clearer picture of the scientific effort of the Federal Government, in which the magnitude of its research effort can be fairly clearly discerned.

This is assisted by the way in which the report directs attention to the major developments in the Federal Organization for Scientific Activities since 1947. In 1953, for example, the research functions of the Department of Agriculture were reorganized, the Bureau of Agricultural Economics being abolished and its functions distributed between the Agricultural Research Service, to which was assigned all the production and utilization research of the Department, except forestry research, and the Agricultural Marketing Service, which was made responsible for marketing research and related statistical and economic research. The Agricultural Research Service was also made responsible for the conduct of the soil conservation research, previously carried out by the Soil Conservation Service, for certain grass and range-management research, formerly done by the Forest Service, and for some of the research and development work from the Foreign Agricultural Service. The Department's expenditure in 1954 totalled 750 million dollars, of which just over 76 million went on scientific activities, in which 3,848 out of its scientific staff of 16,123 (out of a man-power force of 77,405) were engaged.

Nuclear research and production was transferred from military to civilian control in January 1947; but it was more than a year later that the Manhattan Engineer District transferred the last of its contracts to the Atomic Energy Commission, the expenditure of which in 1954 totalled just over 1,417 million dollars; of this total 266 million dollars was on scientific activities, in which 99 out of its 1,009 scientific staff were engaged. The staff of the Commission totals 6,029, but about two-thirds of the research and development programme is conducted in Government-owned facilities operated under contract by industrial and institutional contractors, and of these the Ames Laboratory, Bettis Plant and the Brookhaven National Laboratory have been established since 1947. In its early years, the Commission's research and development programme was organized in five divisions: production, research and development, engineering, military application, and biology and medicine. In 1949 the Division of Engineering was placed within a new Division of Reactor Development, the Division of Research participating in advanced reactor work and supporting research, while in 1954 an assistant general manager of research and development was appointed. It is emphasized that scientists have consistently occupied key roles in the formulation of policy, and close working relations have been maintained between the Division of Military Application and the Armed Forces Special Weapons Project, the Military Liaison Committee serving as the major means of interchange of advice and information with the Department of Defence at the policy level.

---

* National Science Foundation. Organization of the Federal Government for Scientific Activities. Pp. vii+349. (Washington, D.C.: overnment Printing Office, 1956.) 1.75 dollars.

The Department of Commerce, with a total expenditure of nearly 990,000,000 dollars and a staff of 41,539, employs a staff of 6,486 scientists, of whom 2,679 are engaged in scientific activities on which 65,804,000 dollars were expended. Its research activities are on quite disparate subjects and the National Bureau of Standards, the Bureau of the Census, the Weather Bureau and the Coast and Geodetic Survey have a relatively high degree of autonomy. From 1947, increasing use was made of the National Bureau of Standards as a general purpose physical laboratory for defence research; but in 1954 staff and facilities engaged in ordnance work for the Army were reconstituted as an activity of the Army Ordnance Corps and a group engaged on naval missile development was transferred to the Bureau of Ordnance of the Navy Department. A third group, the Institute for Numerical Analysis, was transferred to the administrative control of the University of California at Los Angeles.

The Department of Defense, with a total expenditure of 553,000,000 dollars, of which some 21,675,000 dollars is on scientific activities, employed 191 scientists, excluding all military personnel, in 1954, of whom 89 were engaged in scientific activities. The situation in each of the military departments, in spite of the major changes in the organization for military research and development since 1947, is regarded as still in flux. Under the National Security Act of 1947, the Secretary of Defense has broad responsibilities for unifying the activities of the three military departments and specifically for eliminating unnecessary duplication in research; but in 1953 the President's Advisory Committee on Government Organization recommended abolition of the Research and Development Board which had been established to assist the Secretary of Defense in this task. This Board was responsible for the preparation of an integrated military research and development programme, and for advising on trends in scientific research relevant to national defence as well as for recommending measures of inter-service co-ordination and allocation of responsibilities. The Board was assisted by a staff of several hundred, both civil and military, and by more than two thousand consultants, as well as by a network of committees and panels. The latter, generally consisting of scientists outside the Government, advised on work undertaken in the major scientific disciplines. Besides considering the major programmes and the research and development budget, the Board was concerned with such problems as the assignment of responsibilities, the common use of facilities and the recruitment of scientific manpower, and it developed a system for classifying the research and development effort into categories and programmes, and for relating these to the operational needs of the military services.

The functions of the Board were thus much wider than those of the Defence Research Policy Committee in Great Britain, and its resources were obviously much greater. It is considered that the Board was particularly useful in providing a forum for reconciling the diverse points of view of the three Services and for the exchange of information on activities of common concern. The plan which abolished thi Board in 1953 assigned the responsibility for research and development to a new Assistant Secretary o Defense (Research and Development), assisted by a Research and Development Policy Council. Retaining part of the Board's staff and some of the panel and committees, this Assistant Secretary of Defens has broad powers of formulating and co-ordinatin policy over military research and developmen programmes and exercises other functions for whic the Board was previously responsible.

In June 1955, the Commission on Organization o the Executive Branch of the Government furthe recommended (see *Nature*, 176, 1012; 1955) the re grouping of the functions of the Office of the Secretary of Defense in the four management fields of logistics research and development, personnel and finance each under an assistant secretary. Under thi arrangement the assistant secretary (research an development) would assume responsibilities no divided between him and the assistant secretar (applications engineering). It was also recommende that supervisory duties in each military departmen be divided among those same few assistant secretarie and that each departmental assistant secretar (research and development) should be a person wit a technical background and should co-ordinat research and development within his department This latter recommendation was included in th Reorganization Plan submitted to Congress o May 15, 1956. There is also an Assistant to th Secretary of Defense (Atomic Energy), who is chairman of the Military Liaison Committee, which is th focal point for liaison of policy between the Atomi Energy Commission and the Department of Defense while besides the Weapons System Evaluation Grou there also reports to the Assistant Secretary o Defense (Research and Development), and to each Chief of Staff, the Armed Forces Special Weapon Project, established in 1946.

Organization for research and development differ somewhat in the three Services in the United States In August 1955 the Secretary of the Army establishe the new post of Director of Research and Develop ment, and in September 1955 the post of militar chief of research and development was raised t deputy chief of staff level. Like the other militar services, the Army has established a committee o outstanding scientists and industrialists to advise on its research and development programmes; but besides its responsibility, since June 1954, for co-ordinating the Navy's research and development programmes, the Office of Naval Research has since 1947 been one of the main sources of Government financial support of basic scientific research. The Department of the Air Force was the first of the military departments to establish a higher research and development post (at Secretary level), and in August 1955 appointed a former director of the Bell Laboratories to the post of Secretary of the Air Force. In 1955 about two dozen research centres were engaged almost entirely on contracts for the three military departments.

The Department of Defense in the United States is thus concerned with research, including fundamental research, to a far greater extent than obtains in Great Britain, and the picture of the distribution of man-power given by the recent Zuckerman report (see *Nature*, Oct. 27, p. 887) does not suggest that the nation's research effort is widely different in pattern from that indicated by Mr. Callaghan last July. The 13,900 scientists and engineers in Government service in 1956 represent some 10 per cent of the total employed, and about 7,600 of them are employed in the defence departments. There is, however, no estimate of the proportion engaged on research and development, and the figures for the Ministry of Supply may well include many who in the United States would appear under the Department of Defense.

So far as the United States is concerned, the Department of Defense seems to reflect faithfully, in staff and expenditure, the magnitude of the national pre-occupation with defence, and there appears to be a continuing concern that that effort shall be expended as efficiently and fruitfully as possible from the point of view of the general national interest. There is less apparent evidence of such concern in Britain; and the recent report of the Select Committee on Estimates suggests that, at least in regard to the Navy's expenditure on research and development, there is need for a continuing review by some body with stronger authority than the Defence Research Policy Committee in order to avoid waste and duplication. The very magnitude of the effort in defence research and development in Britain, even when all allowance is made for possible benefit and repercussions in other fields, makes it imperative that there should be continuous co-ordination and upervision to prevent unbalanced development and the expenditure of resources unwisely in too limited a field.

Of the other major changes in the Government rganization for research in the United States since 1947 emphasized in this report, the establishment in 953 of the Department of Health, Education and Welfare must be mentioned. This Department xpended in 1954 some 78 million dollars out of ,000 million dollars on scientific activities; and of ts 35,730 employees, 3,790 were scientists and 1,886 were engaged in scientific activities. Most of the esearch done in the Department is carried out by the Public Health Service, and since 1948 has been largely guided by the Research Planning Council, while at the same time an Office of Research Planning was established to maintain information on current research projects, compile data and develop methods of appraising fields in which research should be expanded or contracted. Most public health research is carried out at the Institutes of Health or under contracts or grants. Some other research in the Department in the biological and physical and social sciences is in support of the Food and Drug Administration, the Office of Vocational Rehabilitation or the Office of Education, and in 1955 the educational research activities of the latter were placed under an assistant commissioner for co-ordination of educational research activities.

The organization for scientific work within the Bureaux of the Department of the Interior, which expended in 1954 some 83 million dollars on scientific activities out of 527 million dollars, has not greatly changed since 1947. It employed 9,307 scientists in a staff of 55,279, and of these 4,725 were engaged in scientific work. The Bureau of Mines was reorganized on a regional basis in 1949 and in January 1955 the number of regional offices was reduced from nine to five. In 1954 the Fish and Wildlife Service extended its activities in fishery technology, market development and fishery biology, and like the Geological Survey, the National Parks Service and the Bureaux of Mines and Reclamation, carries on scientific work in the biological, physical and social sciences. In 1953 the programme staff of the Department was replaced by a technical review staff.

The whole of the National Advisory Committee for Aeronautics, with an expenditure of 57 million dollars, which has doubled its programme since 1947, carries on scientific activities and 2,279 of its staff of 7,150 are scientists. Under the Unitary Wind Tunnel Plan, the Committee is responsible for constructing and operating certain facilities primarily to meet the needs of the Department of Defense and the aircraft industry for the development and testing of aircraft, missiles and propulsion systems.

Of the National Science Foundation itself, it will suffice to add here that its expenditure in 1954 was 7,913,000 dollars, and its scientific staff numbered 37 out of 151. One of the latest of the Federal Government's research programmes is that begun early in 1947 and known as Veterans' Administration. It arose out of the recognition that the demand for medical care by eligible veterans of the Second World War would increase greatly. Since 1947 its support of research has shifted from that by outside investigators on contract to intramural research, and the policy has been increasingly followed of maintaining many small laboratories dispersed among the Administration's hospitals. Of its expenditure of 4,400 million dollars in 1954, 5,343,000 dollars was on scientific activities in which, however, only 334 out of its scientific staff of 10,253 were engaged.

The report directs special attention to two science committees: the Interdepartmental Committee on Scientific Research and the Science Advisory Committee of the Office of Defense Mobilization. The latter was set up in 1951 to direct attention to new developments of science of significance for the national security, and to advise on the effective utilization of scientific resources so as to assure their availability in mobilization. The former, the need for which was emphasized both by Dr. Vannevar Bush's report in 1945 and by the Steelman report in 1947, was established in 1947 to study and make recommendations in relation to the research and development programmes of the Government and the promotion of national welfare; increasing the administrative efficiency of Federal research and development programmes; and Federal policies and practices in support of research.

PROF. NORBERT WIENER: AN AUTOBIOGRAPHY

I Am a Mathematician

By Prof. Norbert Wiener. Pp. 380. (London: Victor Gollancz, Ltd., 1956.) 21*s*. net.

AUTOBIOGRAPHIES of mathematicians are not common; a book, therefore, by Prof. Norbert Wiener dealing with his adult life and mathematical development is of special interest. It can scarcely be said that mathematics ordinarily leads to the kind of life which would interest the general reader, but Prof. Wiener is no ordinary mathematician; his interests are far wider than the title of this book might suggest. They embrace, in addition to most branches of mathematics itself, electrical engineering, aspects of mathematical physics, neurophysiology, statistics and, to use a word which he himself invented, cybernetics. Moreover, Prof. Wiener has travelled extensively in the course of his life. A resident of Cambridge, Massachusetts, he has spent long periods in Cambridge, England, and is familiar with most European countries; of his travels farther afield, he has much to say of interest about Japan, China, India and, in his own hemisphere, Mexico.

The volume under review is not a complete autobiography; it is a companion to an earlier book entitled "Ex Prodigy", and deals with the author's life from the time of his first appointment, at the age of twenty, to the Department of Mathematics in the Massachusetts Institute of Technology, where he is now professor. It is throughout an interesting book, frankly written in a free and readable style. In the preface the author analyses the motives which led him to undertake this work. "Why did I assume this uninviting labour, which at best can add little to my stature as a working scientist and at worst must offer new opportunities for those who may be inclined to criticise me? All in all, I don't know. There have certainly been motives of literary vanity and the desire to show that, both as an individual and as a scientist I have been able to accomplish a task off my regular beat." Further on, other and less subjective reasons are given to which those acquainted with the author and his work will give greater weight.

Part of the book is, of course, taken up with accounts of the author's mathematical researches. These are numerous and varied; even mathematicians may be surprised at the number and scope of the researches which he has inspired. It is characteristic of the man that much of his work has been done in collaboration with others. Attempts to explain mathematical researches in everyday language to non-mathematicians almost always fail, and even Prof. Wiener is not really successful in passages of this kind. These sections of the book—happily short—are the least interesting. Many readers, particularly students of the subject, will enjoy most of all the stories of his contacts with well-known mathematicians of the past and the present. The book abounds with these, all quite short, but often illuminating. Such a one, taken from his account of the mathematical congress at Strasbourg in 1920, may be quoted: "Camille Jordan, who for all his ninety years accompanied us on our pedestrian excursions, was like a memory from the days of Louis Philippe. His recollections dated back to the great days when Cauchy was lording it over French mathematics and forcing all the younger men to pay tribute."

Readers of this book who do not know Prof. Wiener personally will be surprised and pleased to learn that, in spite of his many achievements, he is still only just past sixty years of age. His concluding remarks are: "How many years may be granted me—I do not know; but even now I can feel reasonably sure that my scientific career, though it began early, is lasting late." All readers of this book will sincerely hope that this proves to be so, and that we may, perhaps, have in due course the pleasure of reading a third instalment of this fascinating autobiography.

H. JONES

EXPERIMENTAL DESIGN AND STATISTICS FOR BIOLOGICAL WORKERS

Experimental Design and Its Statistical Basis

By Dr. D. J. Finney. (The Scientist's Library: Biology and Medicine.) Pp. xi+169. (Chicago: University of Chicago Press; London: Cambridge University Press, 1955.) 30*s*. net.

MANY text-books on experimental design tend to concentrate on the combinatorial aspects of the subject and on methods of analysis. (The notable exception is, of course, Sir Ronald Fisher's original treatise.) As a result, many biological research workers and students are discouraged in their efforts to appreciate the subject, while others, more persistent or perhaps more mathematically minded, have their attention directed from the ideas on which theory and practice are based to questions of technical detail.

Dr. D. J. Finney has written his book especially for these workers and students. They should find it a valuable and well-written account of the principles of a difficult subject. The basic ideas are clearly stated, and examples drawn from many fields of biological work are given at each stage of development. The most important experimental arrangements or plans are surveyed, including randomized blocks, Latin squares and incomplete blocks. An excellent short account of factorial experiments is also included. Here rather more prominence is given to fractional replication than to confounding, although the latter is, in practice, the more useful device. There is also a useful chapter on the various types of sequential experiment now under development. This is followed by a discussion of biological assay which serves to show how the principles of experimental design have been applied in a particular field. The last chapter is of special interest, as it deals with topics which are sometimes thought to be outside the province of statistics. Here the author briefly discusses the ways in which statistics can help decisions to be reached on questions relating to the choice of treatments and experimental units, and to the type and number of experiments which should be undertaken.

Technical detail has been kept to a minimum throughout the book; but some discussion of methods of analysis has been considered necessary. The sections including these discussions, particularly those connected with tests of significance, are among the most difficult in the book. Those who are uninitiated in the mysteries surrounding tests of significance may take heart from Dr. Finney's remark on p. 41 that "emphasis has been placed on the making of tests of significance, but more often the real purpose of an experiment is to estimate one or more treatment effects". Indeed, readers would do well to underline these words, for the point they express is all too often overlooked.

Altogether this book contains a considerable amount of advice which biological research workers should find of great value. H. D. PATTERSON

WAR-TIME FOOD RATIONING IN BRITAIN

Food, Vol. 2: Studies in Administration and Control

By R. J. Hammond. Pp. xiii+835. (History of the Second World War: United Kingdom Civil Series. Edited by Sir Keith Hancock.) (London: H.M. Stationery Office and Longmans, Green and Co., Ltd, 1956.) 50s. net.

IN this, the second of three volumes about food control in Britain during the Second World War, Mr. R. J. Hammond provides a number of studies of the methods used for controlling such commodities as fish, milk, eggs and potatoes, which (since they were wholly or mainly home-produced and did not have to pass through a manufacturing process on their way to the consumer) were particularly difficult to regulate. He also deals in some detail with the emergency services which the Ministry of Food devised in case the normal system of distribution should break down under air attack or invasion—the arrangements for supplying bread and milk to bombed cities, the meals provided for air-raid victims and shelterers, the 'iron-ration' dumps, etc. But the part of the book most likely to be of interest to students of administrative techniques is the section which deals, diffusely—and yet here and there with a tantalizing incompleteness—with the numerous inter-related problems connected with consumer rationing.

It would not perhaps be entirely fair to blame Mr. Hammond for the diffuseness. The system which grew up was bewilderingly complex, and its roots, which he examines with some care, were more than a little tangled. Less fortunate than those concerned with rationing in the First World War, the administrators and politicians concerned with such problems in the Second had before them a large body of imposing but, as it proved, largely misleading precedent, handed down by their predecessors, who had dealt very successfully with other, and less exigent, problems some twenty years earlier. "Precedent", says Mr. Hammond justly, "is the uncritical recourse to history"; and he attributes many of the difficulties which the rationers experienced in the Second World War to the *catalogue non-raisonné* officially handed down to them from the First. This indeed, with the important lesson it holds for the future, not only of this but of other large-scale operations, is the central theme of his brief and comparatively crisp concluding chapter. In his view—and having seen the evidence, it is impossible not to agree with him—"It would certainly be a cardinal error to base any future scheme on the forms and documents that were eventually achieved in the Second World War, without regard to the circumstances they were designed to serve, or the processes by which they came into being. This account of those processes will be justified, practically speaking, only if it drives home the warning that the most dangerous legacy a rationing scheme can leave behind is a collection of its forms and instructions."

Mr. Hammond's second main point is that the Ministry was fortunate in having to deal with a war of attrition, a long-drawn-out struggle of a kind to which its rationing system, "dogged, painstaking, a trifle slow in its movements', was eminently suited. He points out that the continuous refashioning it underwent, from 1941 onwards, was untroubled by massive air attacks, heavy movements of population, or frequent and violent changes of ration-levels; and he concludes that "there must remain some doubt whether, even discarding such things, the system would work at all in a war of a different kind".

The feature of the British rationing system which, above all others, made it difficult to work and impossible to introduce quickly, was the tie between the retailer and the consumer. When tea rationing was introduced late in the War, the tie was dispensed with, and despite what had come to be the traditional prejudices of the officials, the simpler system was seen to be quite workable. Mr. Hammond suggests that in this particular connexion Lord Woolton, bringing a fresher mind to the problem, was able to teach officials a useful lesson in method. "The contrast between their freshness in device", he adds, "and their reluctance to bring sustained criticism to bear on basic notions, is a striking feature of British food control."

Mr. Hammond permits himself one or two other significant asides upon various aspects of the official psychology. He mentions in a footnote that the clothing ration book had at first an impressive series of panels inside the front cover, with figures and letters labelled "for official use only". When this disappeared, the Ministry of Food's Rationing Division, says Mr. Hammond, 'asked respectfully and with professional interest, what the change betokened". The reply was that it had been put there to fill up space and make the book appear more official! He quotes, too, in an appendix, the *cri de cœur* of a Stationery Office official charged with the duty of obtaining accurate estimates of the number of ration books that would be needed: ". . . after three and a half years your local people can, if they will use the brains God gave them and the tax-payer is paying for, make far closer estimates than they have yet done".

The iron men of the Stationery Office—with their back-breaking requirement of six months for printing a new ration book—and the registrar-general, perennially preoccupied with the needs of the National Register, emerge indeed from Mr. Hammond's narrative as firmer and somehow more professional figures than the somewhat shadowy officials in the fluctuating divisions of the Ministry itself. Sir Sylvanus Vivian, director of registration in the First World War and registrar-general in the Second, was, in any event, one suspects, too big a man altogether to have been kept out of the centre of this picture either by Mr. Hammond or by successive generations of food rationers. His brief but compelling memorandum on a unit system of general rationing, which is printed here as an appendix and appears in essence to have anticipated the 'points' rationing system by something like a quarter of a century, reveals an imaginative grasp and a generalizing ability which, for one reason or another, were not often apparent in the schemes that followed. Those concerned with the thankless task of drawing lessons for use in the hypothetical next war might do worse than take a glance at it, if not for its matter, then for its manner. It is scarcely longer than this review. FRANK DUNNILL

NUCLEAR MOMENTS

Kernmomente

Von Dr. Hans Kopfermann. Zweite, neubearbeitete Auflage. Pp. xvi+463. (Frankfurt am Main: Akademische Verlagsgesellschaft M.B.H., 1956.) 54 D. marks.

IN this second edition Dr. Hans Kopfermann has completely rewritten and greatly expanded his original book, which for fifteen years stood as a standard work in the field of optical hyperfine structure. During that time the moments of atomic nuclei in the ground state have been studied in many laboratories by the methods of high-frequency spectroscopy, which are here described in addition to the optical methods.

The first three sections of the book deal with the investigation of nuclear moments through their interactions in free atoms, free molecules and condensed phases, respectively. The fourth section gives an account of various nuclear models and compares the moments which they predict with experimental values.

The book is essentially a manual for experimenters. Thus, accounts are given of techniques in high-resolution optical spectroscopy, and in work on atomic- and molecular-beam magnetic and electric resonance, nuclear magnetic and electric quadrupole resonance, and paramagnetic resonance. The methods are well illustrated with examples. The theory is given in detail, both of the various techniques and of the relations between the observed quantities and the nuclear moments themselves. References to original papers number about four hundred. Tables are given of various correction factors, and of the moments of nuclei, their structure according to the shell model, etc.

The contents of this book reflect the wide range of activities in the laboratory which Dr. Kopfermann directs. His experience in these diverse fields enables him to give a first-hand and a balanced account of these branches of nuclear physics. Specialists will welcome the new edition as a reference book for use in their particular fields and as a text-book for instruction in kindred topics.

A consequence of the close association in the text of basic theory with the technique in which it is applied is a certain lack of continuity in the theoretical sections. I would have preferred to find the theory of the hyperfine structure of free atoms in one place, for example, rather than distributed between an introduction, a section on optical hyperfine structure and a section on atomic beam investigations. A further minor criticism is that references are not given to the sources of some of the reported measurements. These are small matters weighed against the vast amount of organized material in this book. Readers who have difficulty with the German text will welcome the English translation which is shortly to be published. G. W. SERIES

MAGIC OF THE EAST

Oriental Magic

By Sayed Idries Shah. Pp. xviii+206+5 plates. (London: Rider and Company, 1956.) 25*s.* net.

IN this work the author has attempted to correlate the magical traditions of the East with those current in the West and to show how oriental influence was potent in moulding not only the lore of Western sorcerers but also the technique through which they claimed to produce their results. Possessed, as he is, with some ethnological training, Idries Shah is naturally interested in the similarities between beliefs and practices in different parts of the world; and thus he has made a special study of the evidence for the diffusion of culture, paying particular attention, as Blau had previously done, to the history of Egyptian magic and to that of Babylonia and Assyria. This book, therefore, supplies the general reader with a useful guide to the magic of the East and the importance that it must have in any appraisal of occidental sorcery.

For the purposes of the scholar, however, the book is somewhat disappointing. The author has tried to do too much in too little space, and thus much of the material is badly co-ordinated and ill-digested. In many passages he shows that he is fully aware of the difficulty of knowing what value can be placed on literary accounts of oriental miracles; yet when he has established contact with a Hindu magician who shows him striking phenomena, he does not attempt any serious investigation but takes refuge in vague suggestions of 'snap-hypnosis'. Anecdote takes the place of the kind of record we should expect from a trained ethnologist, and this is all the more regrettable since Idries Shah appears to have enjoyed opportunities for inquiry which are far from common. Nevertheless, the author stresses a point of view of which too little has been heard in the past. He points out how parapsychology, and, above all, the modern work on extra-sensory perception, are throwing fresh light into the dim recesses of the sorcerer's cave. Amid all the charms, the mumbo-jumbo and the hocus-pocus there may sometimes have emerged flashes of paranormal perception or even strange things. It is here that, as the author says, the true link can be found which connects the sorcery of all ages and peoples, be they oriental or occidental.

The book is well produced and the list of authorities convenient for reference. It is surprising, however, that, although there are two references to the famous "Book of Changes", there is no discussion of the modern use of the technique in its relation to theories of psycho-kinesis. E. J. DINGWALL

Manual of Elementary Practical Chemistry

By Dr. R. D. Brown and Dr. T. A. O'Donnell. Pp. x+185. (Melbourne: Melbourne University Press; London: Cambridge University Press, 1955.) 30*s*. net.

THE practical work dealt with in this book is that arranged for first-year students at the University of Melbourne. The syllabus consists of familiar gravimetric and volumetric determinations, qualitative analysis, including the identification of cations occurring in the same group, the purification of substances, and the preparation and analysis of some typical organic compounds. In both the organic and inorganic analysis semi-micro methods are exclusively used. There are no inorganic preparations and no exercises in physical chemistry. The scheme of work, therefore, does not quite meet the requirements of Intermediate examinations in Britain. The syllabus is intended to be worked in conjunction with a course of lectures on the relevant physical chemistry.

An uncommon feature is the singular use of the Bronsted–Lowry concept of acid throughout the book. This theory is first clearly expounded and then, in due course, applied to the work in hand: that is, to neutralization and redox reactions, solvated and complex ions, the calculation of *p*H, the construction of titration curves, indicator action and solubility-product phenomena. The scope of the practical work is not extensive, but what is done is ntegrated with the theory and done thoroughly. Thus preparations and determinations are limited to typical examples, and mixtures for analysis are deliberately restricted in difficulty. The idea, a sound one, is to avoid confusing a student with overmuch technical detail, so that he may be encouraged to devote his energy to the mastery of the underlying principles.

Students using this book on such a course should emerge with an understanding of elementary analysis well calculated to help them make rapid progress with more advanced work. G. FOWLES

Treatise on Inorganic Chemistry

By Prof. H. Remy. Vol. 1: Introduction and Main Groups of the Periodic Table. (Translated by Prof. J. S. Anderson. Edited by Prof. J. Kleinberg.) Pp. xxi+866. (Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd., 1956.) 105*s*.

THIS English version of a successful German work, with modifications and improvements by the translator, has many good features. It is based on the periodic system and has chapters on many aspects of theoretical and physical chemistry which are essential in a proper understanding of inorganic chemistry. These include valency, crystal structure, bond types and resonance, co-ordination, and the modern theory of acids and bases. Industrial methods and uses are given. Physical properties and mineral compositions are tabulated.

The straightforward treatment of inorganic chemistry is generally good, but is uneven: some topics (for example, the peroxycarbonates) are dealt with superficially and not always in accord with modern knowledge, while others (for example, the lower oxides of iodine) are not even mentioned. Perhaps these latter will be included in the second volume. The modern view of the composition of bleaching powder is not given. A few minor errors were noticed: for example, S_2O_3 is green, not blue, and the melting point of ClO_2 is −59°, not −76°. References to literature are given in the text and short bibliographies at the ends of chapters.

This is a valuable and important book, which can be recommended for study and reference.

Topological Dynamics

By Prof. Walter Helbig Gottschalk and Prof. Gustav Arnold Hedlund. (American Mathematical Society Colloquium Publications, Vol. 36.) Pp. vii+151. (Providence, R.I.: American Mathematical Society, 1955.) 5.10 dollars.

TOPOLOGICAL dynamics might claim to have its roots in the dynamical astronomy of the late eighteenth century; but its present developments spring from the qualitative, topological methods introduced by Poincaré to replace quantitative methods of tackling some of the intractable problems of celestial mechanics. A further major contribution was made by G. D. Birkhoff in his systematic study of topological methods in dynamics. The subject has now become a branch of topology, wherein are studied those topological properties of transformation groups which can trace their origin back to problems in classical dynamics. References to orbits, periodicity, flows, all used in highly technical senses, only faintly recall the dynamical origins.

Profs. W. H. Gottschalk and G. A. Hedlund have organized their material admirably, so that definitions, axioms, notations and proofs are clearly identifiable, and arguments are efficient and precise. But so concise a treatment of so austerely abstract a topic has made the book difficult to read, and in order to keep the volume within reasonable compass, some knowledge of set theory and of topological groups is assumed; in fact, the relevant parts of Bourbaki should first be mastered. It is thus a book for the expert, not the novice. T. A. A. BROADBENT

What Flowering Tree Is That?

A Handbook for the Tropics. By Edwin A. Menninger. Pp. 110+4 plates. (Stuart, Florida: Edwin A. Menninger, 1956.) Cloth, 3 dollars; Paper (without colour plates), 1.50 dollars.

FLORIDA has the good fortune to possess a climate and a variety of soils ideally suited for the cultivation of flowering tropical trees. She has also produced a refreshingly original and enterprising person in the author and publisher of this little book, which describes a thousand such trees now growing in his garden at Stuart, where he keeps open house on Sunday afternoons. For many years he has imported seed of unusual and showy trees and shrubs from every tropical country in the world, and now 'The Flowering Tree Man', as he is called, hopes that other residents of Florida, the 'State of Flowers', will follow the example set by his initiative.

The trees are arranged by families in alphabetical sequence, and the common name is given precedence, followed by the Latin name and a short informal description. A few spectacular vines are listed separately at the end of the book, which is illustrated by many small black-and-white photographs and a few full-page plates in 'Kodachrome'. The botanical names are not of importance to the author, though he claims they are correct: "I don't care what you call these trees; my sole interest lies in the beauty they can produce". His enthusiasm is infectious, and the Sunday callers may be envied their unique experience with the author and his book as their guide. N. Y. SANDWITH

GENERAL ASPECTS OF AUTOMATION

A JOINT meeting at Sheffield of Sections F (Economics) and G (Engineering) of the British Association, held on September 3 and 4, discussed various aspects of automation. Under the chairmanship of Mr. A. C. Hartley, president of Section G, Lord Halsbury introduced the subject by saying that the public is substantially misinformed about it. He emphasized that it is virtually impossible to define automation and that different people define it in quite different ways. In discussion at the end of the meeting, he pointed out that in the three papers by Mr. J. F. Coales, Prof. H. D. Dickinson and Mr. George Doughty, the word 'automation' could have been substituted, without affecting the meaning, if it had been replaced respectively by some such term as increased mechanization, improved productivity or production engineering. He pointed out that the advent of automation as some new technical invention is in effect a rumour which has been taken up by the Press and become emotional rather than factual. "The automatic factory and the automatic office," he said, "have arrived, but they are no more than the development of improvements in production that have been going on for many years. The only really new technique which has been injected into industry is the digital computer." He said that automation is most likely to affect the section of industry which produces what are called consumer durables, that is, motor-cars, radio, television, washing machines, etc. It is very unlikely to be widely used in heavy engineering, shipbuilding, agriculture, mining, textiles and highly mechanized industries. Unfortunately, consumer durables are the first to be hit when there is any form of financial stringency, since when times are bad it is these goods which families first go without, making the motor-car or radio or washing machine do another few years, rather than spending less on food or on amusement. He believes that although automation will cause men and women to change their jobs and perhaps move to new areas, widespread unemployment is not a danger because in any event changes are unlikely to come about quickly.

Lord Halsbury was followed by Mr. J. F. Coales, of the Engineering Laboratory, University of Cambridge, who read a paper entitled "The Historic and Scientific Background of Automation".

"Automation", he said, "is no more than the evolution of improved methods of replacing human and animal labour by energy from natural sources and the development of tools to control these processes in order to relieve the operators of the burden of watching them or of making calculations and adjustments." This process, stimulated by man's inherent laziness, has been going on for at least two thousand years, first by the use of gravity, water- and wind-power, and later by the use of solid fuels, and now by the use of nuclear power. This has resulted in electrical energy now costing only about one five-hundredth of that of human labour, so that there is an enormous incentive to replace human labour by natural energy wherever possible; this has resulted in very rapid advances during the past few years. Water trip-hammers are known to have been in use in 350 B.C., and water-wheels existed in China, Persia and the West in the first century B.C. The prototype of the automatic factory is undoubtedly the windmill, since by the end of the eighteenth century there were many thousands in Britain, incorporating automatic controls so that they could be completely operated and controlled by one man, who could leave the mill to run untended while he dressed the stones not in use, tested the quality of the meal, or hoisted sacks to fill the automatic hoppers in just the same way as maintenance, quality control and transport have to be carried out to-day.

Mr. Coales then recounted the developments which took place in the textile industry during the eighteenth century and the development of calculating machines which started with that of Blaise Pascal in 1642. Pascal was followed by Liebniz, who designed what was the precursor of the modern desk calculator, while Charles Babbage proposed a 'difference engine' in 1822 which was the precursor of the modern digital computer. These developments led up to the automatic office, which is now an accepted fact.

Automatic production-methods were then discussed, and Mr. Coales outlined the development of automatic transfer machines for the motor industry. This led on to the organization of the automatic factory of the future and developments which will be necessary to bring such a project to a successful conclusion. Most of the operations required can now be carried out automatically, although automatic assembly and automatic inspection and test present considerable difficulties. There is still, however, a long way to go from having the techniques available to being able to set up such a factory as an economic success.

Mr. Coales then discussed the effect of automation on labour; for this purpose he classified human activity under the following eight headings: (1) manual labour; (2) watching and controlling; (3) memory; (4) calculation and correlation; (5) writing and giving orders; (6) decision making; (7) research and invention; (8) design of product and plant.

Of these, the first five, it has been shown, can be replaced by machines already existing or under development; but at present it is not envisaged that there is any possibility of machines usurping the higher attributes of man inherent in the last three categories, although computing machines are making it easier for him to marshal the facts on which to make decisions and to carry out the calculations required in research and invention and in the design of product and plant. He is, therefore, being released by automation from the part he has played as a beast of burden. The challenge of automation is for us to show that by education we can train a large proportion of our manual workers to take their place in the army of skilled maintenance engineers that will be required, and eventually to swell the ranks of qualified engineers and managers who must provide the creative thought. Experience shows that the more a factory becomes automatic, the more the labour has to be transferred from the unskilled to the skilled classes, and that also there is an ever-increasing demand for the professional engineers to design new products and plant. In considering whether the automatic factory is likely to bring serious unemployment, it is important to remember that the capital expenditure involved in setting up any automatic factory is enormous—many times that for a conventional factory—and it is quite impossible that the change-over in industry as a whole can be rapid. It is also worth noting that in the United States, manufacturing industry employs only 25 per cent of the total labour force, and clearly, not all industries are suitable for automation. Some redundancy may occur in other industries, such as banks and insurance offices, where clerks may be replaced by computing machines; but on the other hand, increased production due to automatic factories will inevitably increase the numbers required in the distributive trades.

In the second session of the morning, under the chairmanship of Prof. Gilbert Walker, president of Section F, Prof. H. D. Dickinson, of the University of Bristol, read a paper on the "Economic Effects of Automation". He said that long-period results of automation may be expected to be almost wholly for the benefit of mankind, since it will in the long run enable the joint efforts of human beings to produce more material goods with less expenditure of time and effort than before. Certain very long-term considerations do, however, obtrude themselves, namely, problems arising out of the use of leisure, the sufficiency of supplies of natural raw materials and very long-run consequences of population growth; but these he is confident can be solved by a robust application of scientific technique and a rational attitude towards problems of human ecology. He believes that the best way of ensuring the good effect of automation is by price reduction; but unfortunately, in Britain, both management and labour seem to be averse to this method. Organized labour thinks first of obtaining as much benefit as possible for the workers in the form of higher wages and shorter hours, or both, and management seems to think of price reduction as something almost indecent. To obtain the full advantages of automation, workers must be willing to change jobs and re-train for new jobs. Emphasis on traditional demarcations and rules must go. We must avoid a situation, too, where the benefits are monopolized by a small rich class giving Babylonian luxury to the few, which would give rise to a politically irresistible demand for higher taxation and nationalization of industries subject to automation. If this can be avoided, the benefits would be widely spread and there would be a big increase in services rendered to the community generally, such as those of teachers, medical men, dentists and nurses. "Automation", he said, "involves changes in the relative intensity of demand for the various agents of production. As between capital and labour, it is likely to increase the demand for capital relative to that for labour, and as between the different grades of labour it is likely to increase the demand for the highest grades of skill and reduce the demand relatively for practically all other grades. This raises an important political and social question, since in the biggest Trade Unions the numerical strength is now in the unskilled and semi-skilled grades, which are therefore likely to react violently against any tendency to put into reverse the egalitarian tendency in the movement of earned income that has shown itself so strongly during the last fifteen years. There is a danger in the tendency towards increased inequality between workers in different industries or between employees of different firms, which would be intensified by any general introduction of profit-sharing or co-partnership schemes, or even of a guaranteed annual wage on the model now popular in the U.S.A."

Following Prof. Dickinson, the large audience was delighted by a short, but excellent, contribution from Mr. George Doughty, general secretary of the Association of Engineering and Ship-Building Draughtsmen. He said that among skilled workers, automation is generally understood to offer no immediate threat to security, and is a challenge which leads to new opportunities; but he said many unskilled workers are not happy about it. "British workers," he said, "do not resist technological advances, but they resist being fired without reasonable alternative employment." He urged managements to consult work-people about changes in methods of production and to seek their co-operation. This would involve receiving suggestions, intelligently discussing alternative jobs, formally assessing compensation and discussing plans for re-training displaced workers for whom new jobs cannot be created. Some redundancy would be inevitable and planning is essential to retain maximum employment. The workers would argue vigorously for this to be tackled by shorter working hours, longer holidays and earlier retirement. "Consultations," he said, "should not be merely a formal intimation by the management of the dismissal of large numbers of work-people."

The meeting was then thrown open to general discussion, and one speaker raised the question of the possible shortage of raw materials if automation became general. He was followed by Mr. E. A. Watson, chief engineer of Joseph Lucas, Ltd., who referred to the common belief that mass-production and automation result in a product of poorer quality He said that in every case with which he had been associated, increased mechanization or automation had resulted in a marked improvement in the quality of the finished product.

On the following morning, September 4, a number of specialist papers on automation were presented to Section G, under the chairmanship of Prof. A. L. Cullen, of the Electrical Engineering Department, University of Sheffield In the first of these, Mr. A. J. Young, of Imperial Chemical Industries, Ltd., discussed the importance of automatic control in the process industries and gave a general description of the methods used at present. He gave a discourse on the fundamental principles underlying process control and indicated what would probably be the future developments.

Mr. D. T. N. Williamson, of Ferranti, Ltd., then presented a paper entitled "Computer-controlled Machine Tools". He said that the concept of high-speed digital computers allied to servo-mechanisms with accurate feed-back systems offers tremendous possibilities for improvement in the field of industrial controls. Although automatic machine tools have been in use for at least thirty years, they have not been applicable to the production of small quantities of complicated parts, owing to the length of time required to design, make and instal the necessary cams. However, the application of digital computer and feed-back servo-mechanism techniques to machine tools have enabled universal machine tools to be created which give fully automatic production with the equivalent of setting time, now called programming time, reduced on the average to less than one-fifth of the time necessary to make one component by hand. The computer can, at very high speed, accept basic dimensional and machining information in numerical form which often allows much of the detailed drawing procedure to be omitted. The computer then calculates the movement of the cutting tool to machine the component and records the information on magnetic tape. A control unit associated with the machine tool into the reader of which this tape is placed controls servo-mechanisms, which move the slides in accordance with the instructions on the tape. Dr. Williamson said that the possible uses of a control system of this type go far beyond the limited field of machine tools, and the principle is applicable to all industrial processes.

The next paper, presented by Dr. Denis Taylor, of the Atomic Energy Research Establishment, Harwell, was entitled "Atomic Energy and Automation". Dr. Taylor said that automation has a large part to play in the development of atomic energy for two reasons. First, there are those processes which arise in any industry which, although they can be carried out manually, can be carried out on a large scale more satisfactorily by automatic machinery; and secondly, there are processes peculiar to atomic energy which, because of the radiation hazards, are difficult or impossible to carry out manually. Dr. Taylor described various automatic equipments used in the laboratories for reducing the amount of assistant labour that would otherwise be required for carrying out routine measurements. Such machines are capable of working night and day with very little attention and quickly pay for themselves. Automation also finds application in the atomic-energy field in the processing of experimental data, such as in the study of cosmic-ray showers. A common experiment is the observation of the coincidence-rate of two counters as a function of their separation, and this may be extended to include the coincidence-rate of three or more counters as a function of the size of the geometrical configuration, triangle or square, etc. An enormous amount of data will be obtained in quite a short time, and some form of automatic processing of the data becomes essential. In the atomic-energy field, as in the chemical industry, there has been a change-over from batch processing to continuous flow techniques, and automatic control for plants processing radioactive materials is particularly attractive because of the health hazard. Another problem which arises is that of handling the reactor fuel elements. After a nuclear reactor has been in operation for some time, re-cycling of active fuel elements may be required in order to re-use the elements. These elements will be highly radioactive and could not be handled directly. Here, therefore, there is an important problem in the field of automation.

The next and last paper, "Conscious Machines", was presented by Mr. J. Sargrove, who, as early as 1948, set up an automatic line in Britain for making radio receivers. Mr. Sargrove spoke mainly of automatic machines for inspecting and controlling the production of a number of small and common commodities. He showed a film to illustrate different types of electronic problems which occur in industry, starting with a very simple application and leading up to more complex ones, as follows: (1) automatic electronic stock-keeping; (2) automatic printing of calendars; (3) automatic production of continuous stationery; (4) automatic processing of knitted 'Nylon'; (5) automatic extrusion of plastic rods, such as knitting needles; (6) high-speed weighing of pieces of dough, and automatic control of a dough divider in a bakery; (7) high-speed counting, batching and packaging of tablets in the pharmaceutical industry.

Having given these examples, Mr. Sargrove went on to say that if we are genuinely to increase our standard of living with full employment, this can only happen by an increase in the total production of goods and commodities. If all human beings are fully employed, this extra output, which we all desire, can only come from the more intensive use of automation. In his experience, no employee has ever been discharged from a firm due directly to the introduction of automatic machines.

THE CHROMOSOMES OF MAN

By Dr. C. E. FORD and J. L. HAMERTON

Medical Research Council Radiobiological Research Unit, Atomic Energy Research Establishment, Harwell, Berkshire

ACCURATE knowledge of the number of chromosomes and of their behaviour in mitosis and meiosis has illuminated the genetic analysis of many species. The outstanding example, of course, is *Drosophila melanogaster*[1]. *Zea mais*[2] and *Oenothera lamarckiana*[3] are notable examples from the plant kingdom. Chromosome observations have been of some value even in the fungus *Neurospora crassa*[4], and recent work[5] has given promise that the genetics of the house mouse may benefit in the same way. There is therefore good reason for supposing that the genetic study of man himself may be advanced by reliable information about his chromosomes. The unique features of the human genetic milieu—the alterations in breeding structure[6], the changing selection pressures[7], and the possible influence upon mutation-rates of the environmental changes of the past two or three centuries—are all in great need of study and measurement in order to be able to estimate their effect upon the genetic structure of future human populations, and it is possible that a thorough examination of the chromosomes in a range of human groups would make a useful contribution. The rapid and economical technical methods now available would enable relatively large numbers of individuals to be examined and should make a new approach to human cytogenetics both possible and rewarding. Nor is this the only field in which chromosome observations may be of value to human biology. The rapid pace at which knowledge of the chromosomes in tumours of experimental animals[8] is advancing suggests that the chromosomes may have an increased part to play in the investigation of human neoplastic conditions; and they may also be able to assist in the causal analysis of infertility, at least in the male[9].

The first attempt to determine the number of chromosomes in human cells would appear to have

been made by Hansemann, who in 1891 reported three cells from 'normal human tissues' with 18, 24, and more than 40 chromosomes, respectively[10]. From then until the appearance of de Winiwarter's classical paper[11] in 1912, diploid numbers ranging from 16 to 36 were reported, the balance of opinion being in favour of 24. De Winiwarter claimed that there were 47 chromosomes at metaphase in spermatogonia, and 23 autosomal bivalents plus an unpaired *X* in primary spermatocytes. Painter[12] in 1921 reported the presence of a small *Y* chromosome in males and was the first to assert that the correct diploid number was 48 in both sexes[13]. In the following two decades most authors[14] supported Painter's position; but de Winiwarter and his associates[15] adhered to the opinion that there was only a single sex-chromosome at meiosis in the male and 47 chromosomes in spermatogonia. Koller's account[16] of the behaviour of the sex-chromosomes in spermatocyte meiosis brought this period to an end just before the outbreak of the Second World War. From then on, the value of $2n = 48$ in both male and female remained unchallenged for nearly twenty years, and it seemed that the chromosome number of man had finally been established. However, in a very recent paper[17], Tjio and Levan report consistent counts of $2n = 46$ in cultures of lung tissue taken from four aborted embryos, and refer to further counts of $2n = 46$ obtained by Hansen–Melander, Melander and Kullander in preparations of liver, also from aborted embryos. The regular loss of two chromosomes during development of the organs or growth of the cultures would seem to be most unlikely, and the implication was clear that the generally accepted figure of $2n = 48$ might, after all, have been in error.

A re-examination of spermatocyte and spermatogonial chromosomes was obviously desirable, and we have been fortunate in securing testis tissue from three males, aged forty-seven, fifty-three, and sixty-three years respectively. The material was obtained at the Churchill Hospital, Oxford, from fresh operative specimens at the moment of removal from the body. The tubules were teased out in hypotonic fluid, allowed to remain in the fluid for 30 min. at room temperature, fixed in acetic alcohol and stained by the Feulgen procedure. Squash preparations were made in the usual way. Many of them contained one or more small clusters of spermatocytes in the most suitable stages for counting, namely, diakinesis and first metaphase. Obviously broken cells with scattered chromosomes, and cells in which the chromosomes were clumped or badly fixed, were rejected. Counts were made on all the remainder and are summarized in Table 1. It will be seen that the great majority contained 23 bivalents, and that our results therefore complement those of Tjio and Levan. Examples of these cells are shown in Figs. 1 and 2. In a few cells at late diakinesis and first metaphase, the *X*- and *Y*-chromosomes were unpaired and usually well separated from each other, so that 24 bodies were counted (Fig. 3). Precocious disjunction (already reported by Koller[16] in sectioned material) would seem to be the most likely explanation of the non-association of *X* and *Y* in these exceptional cells, although some cases may have been due to the rupture of the terminal connexion between them during the making of the preparations. The

Table 1. COUNTS OF NUMBERS OF BODIES PRESENT IN FIRST SPERMATOCYTES AT STAGES FROM LATE DIPLOTENE TO METAPHASE

Patient	Age	First spermatocytes containing : 22 bivalents or fewer	23 bivalents	22 bivalents $+ X + Y$

2	53	3	39	11
3	47	2	29	3
Total		14	149	25

few cells recorded as containing fewer than 23 bivalents, although apparently intact, may have been damaged and we attach no significance to them.

Relatively few spermatogonia were observed in mitosis and, in contrast to the spermatocytes, most of them were broken and their chromosomes scattered. We have noticed similar fragility of spermatogonia in several other species of mammals. Nevertheless, a few clear counts of 46 chromosomes were obtained in apparently intact cells, one of which is shown in Fig. 4. It is noteworthy that the centric constrictions are sometimes greatly elongated in from one to four chromosomes.

In the great majority of first spermatocytes examined, the sex chromosomes were associated terminally, the attachment varying from a relatively long thin thread to a condition in which only a slight narrowing indicated where X ended and Y began. All these associations could be interpreted as terminal chiasmata, although Sachs[18] denies that true chiasmata occur in the sex-bivalent of man. The few cells in which the sex-chromosomes were present as univalents have been mentioned. In one cell only the X- and Y-chromosomes appeared to be associated in a different manner. The structure of this bivalent was not resolved with certainty; but its appearance strongly suggested the presence of a sub-terminal chiasma, or possibly that it was a 'symmetrical' sex-bivalent as described by Koller[16]. This single observation can scarcely be construed as support for the possibility of crossing over between X and Y: on the other hand, the observations as a whole are certainly not inconsistent with the occurrence of partial sex-linkage[19].

Koller[16] figured diplotene bivalents with many chiasmata. This observation we confirm. The largest autosomal bivalent frequently has five chiasmata; and some of the others may have four. In well-fixed cells the successive loops can be clearly seen in planes at right angles to each other, as in the classical plant and orthopteran species. In cells where the bivalents are rather crowded, it would not be difficult to mistake a terminal loop for an additional small bivalent. The numbers of chiasmata were counted in some of the clearest cells at stages from late diplotene to mid-diakinesis, and the results are given in Table 2.

Since the hypothesis that each cytological chiasma represents a single genetic cross-over was first put forward, evidence in its favour has been steadily accumulated, although its general validity has been questioned[20]. Assuming it to be true in man, the counts of chiasmata can be used for making an estimate of the total genetic length of the human chromosome set, on the basis that one chiasma is equivalent to 50 centimorgans. The over-all mean number of chiasmata per cell is 55·9 and the estimate of genetic length is, therefore, 27·9 morgans. However, should there have been any reduction of chiasmata by terminalization, the observed frequencies will have been somewhat less than the original frequencies, with the result that the estimate of genetic length will be a minimum one. So far as we are aware, the only other mammalian species in which estimates of total genetic length of chromosomes have been obtained is the house mouse, and it is satisfactory to note that the estimates obtained from Slizynski's chiasma counts[21] and by Carter's linkage-data method are in reasonable agreement. The two methods yield values of 19·2 and 16·2 morgans respectively[22]. It would appear that, genetically, the chromosomes of man are at least half as long again as the chromosomes of the mouse.

Table 2. COUNTS OF CHIASMATA AT STAGES FROM LATE DIPLOTENE TO MID-DIAKINESIS

Patient	Age	Cells counted	Chiasmata per cell: Range	Mean
1	63	11	50–62	54·4
2	53	6	52–62	57·1
3	47	6	50–63	57·1
Total		23	50–63	55·9

The reservation should be made that the estimate of 27·9 morgans strictly applies to middle-aged and elderly males only. However, in the mammalian species studied genetically, recombination fractions do not in general differ much with age or sex. As a rule the values are slightly higher in the female sex, although there are some exceptions. There is therefore no reason for supposing that genetic lengths will be greatly different in the two human sexes, and until direct estimates have been obtained at oogenesis the value of 27·9 morgans derived from chiasma counts at male meiosis may be regarded as an approximate minimum estimate for the female also.

Two comments in connexion with the high frequency of occurrence of chiasmata are relevant: it reflects the rarity with which autosomal linkages have been detected in man; and it implies a genetic system in which there is a rapid re-assortment of the genotypic variability, which, according to Darlington[23], is the mark of a plastic species able to adapt itself readily to diverse environmental circumstances.

Returning to the question of the chromosome number of man, how should the discrepancy between the recent counts and the older ones be explained? Although the occurrence of numerical chromosomal polymorphism has now been established within populations of one mammalian species[24] and may exist in a second[25], it is most unlikely that the occurrence of a similar situation in the human species could provide the whole answer—the probability of drawing by chance from such a polymorphic population seven successive individuals (four of Tjio and Levan, three recorded here) with 46 somatic chromosomes after an even larger series all with 47 or 48 would be altogether too low. Nevertheless, the rare occurrence of individuals with the latter numbers is not excluded. The alternative is to assume a persistent error, and this we consider to be the more likely explanation. (It is of interest to note that in his preliminary communication on the subject, Painter was uncertain whether the diploid number was 46 or 48.) Three features of the behaviour of human chromosomes which have already been mentioned may have contributed to erroneous counting. In somatic cells and spermatogonia, one or more of the exceptionally long centric constrictions seen in some chromosomes may have been overlooked, with the result that each arm was counted as a separate chromosome; and in spermatocytes, counts of 24 bodies could have arisen as a consequence of precocious disjunction of X- and Y-chromosomes, or from mistaking an end loop of one of the larger elements for a separate bivalent. In view of the much closer packing of the chromosomes in the cells, these difficulties would have been much more serious with the older sectioning technique. Undoubtedly the adoption of the squash method[26] and ancillary treatments for dispersing the chromosomes within the cells[27] is bringing about a great change in mammalian chromosomal cytology, and it is to this technical improvement that the rectification of the error—if such it be—must primarily be attributed. The crux lies no longer in the microscopy but in the preparative technique. The weary hours of toil which the pioneers must have spent at the microscope is reflected in de Winiwarter's *cri de coeur,* "J'ai perdu un temps énorme à répéter des numérations fatigantes et j'avoue aussi, très fastidieuses". The wonder is that there is so little to alter.

We acknowledge gratefully the help and interest of Mr. G. E. Maloney, who provided us with the material upon which the study was based. The efficient technical assistance of Mr. G. Breckon is also acknowledged.

PROPERTIES OF MAGNETIC MATERIALS

THE final session of Section A (Physics) of the British Association was held on September 5, and appropriately for a Sheffield meeting was devoted to three papers dealing with various aspects of magnetism.

Prof. W. Sucksmith, of the Department of Physics, University of Sheffield, gave an outline of the developments leading to present-day production of magnetically hard materials for permanent magnets and magnetically soft materials for use in dynamos, transformers and other electromagnetic devices. The desirable characteristics of the two types of material are respectively high coercivity and high permeability. Until the early years of the twentieth century, tool steel was used in the manufacture of permanent magnets and no special materials were produced for the purpose. Subsequent empirical development culminated in the production of oxide magnets (cobalt ferrite, $CoO.Fe_2O_3$) by Kato and the iron–aluminium–nickel magnet steel, the parent of many present-day magnet steels, by Mishima.

A number of interesting problems of fundamental importance have arisen from considerations of the magnetization processes responsible for the high coercivity of permanent-magnet materials. Modern theories of magnetization processes are based on refinements of the theory of magnetic domains originally proposed by Weiss. In general, it is supposed that ferromagnetics are subdivided into domains in each of which the elementary magnetization vectors lie along one of two or more preferred directions; domains characterized by different preferred directions are separated by domain boundary walls. In the demagnetized state the domain arrangement is such as to produce zero external magnetization. However, when a magnetic field is applied the domain walls move, domain magnetization vectors rotate from the preferred directions and the specimen becomes magnetized. Materials in which domain boundary movements are greatly impeded by structural and other imperfections are magnetically hard and have applications as permanent magnets. Néel, in his theory of 'disperse fields', has considered these aspects in detail. High coercivities may also be obtained in materials in which magnetization cannot occur by boundary movement but by rotation of domain magnetization vectors from one preferred axis to another. Thus if the dimensions of an isolated ferromagnetic particle are sufficiently small ($\sim$ 300 A.), it is energetically unfavourable for boundary walls to be created and the particle is a single magnetic domain. No boundary movements are involved in the magnetization of an assembly of single-domain particles; only rotations of the magnetization vectors may occur against anisotropy forces arising from the shape of the particles, crystalline anisotropy or strain anisotropy. It follows, as Néel in France and Stoner in Britain have shown, that prolate ellipsoidal particles departing by relatively small amounts from a spherical form will possess high coercivity. This work has stimulated the production of compacts of oriented single-domain particles of acicular shape for use as permanent magnets and also for magnetic recording tape.

In this connexion work on single-domain assemblies which is being carried out at Sheffield was also mentioned. Copper–iron alloys containing about 1 per cent of iron may be rapidly quenched from high temperatures and preserve the iron in solid solution. Precipitation of the iron in fine particle form can be induced by heat treatment at lower temperatures and may be interrupted at various stages to investigate the magnetic properties. Alloys of coercivity 500 oe., but with low remanent intensity of magnetization, have been produced in this way. It has also been found possible, by cold drawing the alloys, to orient the precipitate. In this way cold-drawn alloys with precipitated iron and nickel have been prepared with coercivities of greater than 1,500 oe. and 670 oe., respectively.

The necessary characteristics of magnetically soft materials of high permeability were then considered as the converse of those possessed by permanent magnet materials. For high permeability the material must have low magneto-crystalline anisotropy and low magnetostrictive deformation in order to minimize the effect of internal strains. For example, the composition of the alloy of iron–silicon–aluminium of the highest permeability is 84 Fe, 10 Si, 6 Al; for which the values of magnetocrystalline anisotropy and magnetostrictive deformation are least.

Prof. Sucksmith's conclusions were that, so far as the conducting magnetic materials are concerned, both soft and hard materials appear to be within sight of a stage where the relevant quantities are only reached under exacting laboratory conditions. The practical applications are becoming more and more controlled by manufacturing expediency. It also appears that the rapid extension of the alternating current applications of the non-conducting magnetic materials, particularly to high frequencies, gives a promise of a greatly expanded future.

In a paper by Dr. E. W. Gorter, of the Philips Research Laboratory, Holland, some aspects of the properties and underlying theory of non-conducting magnetic materials, the ferrites, were discussed. The unit cell of a ferrite may be represented by the formula $M_8Fe_{16}O_{32}$, where M is a divalent metal; the crystal structure is cubic spinel. The metallic ions occupy two types of site in the lattice: A-sites for which there is tetrahedral co-ordination with oxygen ions, and B-sites having octahedral co-ordination. Dr. Gorter exhibited a model of part of the unit cell which convincingly illustrated the possible magnetic couplings between the ionic moments of metallic ions occupying A and B sites. In general, the ionic moments are aligned mutually parallel or antiparallel.

The characteristics usually required of ferrites in alternating-current applications are high permeability and low loss. In turn, these characteristics depend on the spontaneous magnetization of the material, I_S, the magneto-crystalline anisotropy, K, the magnetostrictive deformation, λ, and the internal stresses and defects. The latter are inevitably introduced during the sintering processes used in the manufacture of ferrites and can never be entirely eliminated by annealing. Systematic investigations of the factors which influence I_S, K and λ (chiefly by Dr. Gorter and his colleagues) now make it possible for ferrites to be 'tailor-made' and suitable for a wide variety of applications. Thus, it follows from the theory of ferrites, originally developed by Néel, that the addition of zinc leads to an increase of spontaneous magnetization. Gorter has shown that this increase is limited by the fact that, when the zinc content exceeds a certain limit, the ionic moments are no longer mutually parallel or antiparallel. This leads to a reduction of spontaneous magnetization. The total magnetic moment of a magnetic ion is the resultant of two components, one due to electron spin and the other arising from the orbital motion of the electrons. There is a direct connexion between the magnitudes of the magnetocrystalline anisotropy and the orbital contribution to the ionic moment. Thus the orbital contributions to the moments of cobalt and nickel ions are 0·3 and 0·7 Bohr magneton, respectively, and cobalt and nickel ferrites are characterized by large magnetocrystalline anisotropy. However, the magnetocrystalline anisotropy coefficients of cobalt and nickel ferrites are of opposite sign; in cobalt ferrite the directions of easy magnetization are along cube edges, whereas for nickel ferrite cube diagonals are easy directions. Thus by sintering nickel ferrite with a small quantity of cobalt ferrite, it is possible to prepare materials in which there are only small magnetocrystalline anisotropy forces impeding rotation of the magnetization vectors and the permeability is high. Materials of this type purposely made with defects and air pores are found to have a low-temperature coefficient of permeability over a range of 60° C. The magnetostriction of ferrites can also be controlled by preparing mixed ferrites. The majority of ferrites have positive magnetostrictive deformation, that is, they expand on magnetization in a direction along the applied field. However, ferrous ferrite, $FeO.Fe_2O_3$, contracts on magnetization and has a negative magnetostriction. The magnetostriction of a mixed ferrite can thus be made zero if it contains the correct proportion of ferrous ferrite.

The concluding section of Dr. Gorter's paper dealt briefly with some of his recent work on dipole–dipole interactions in ferrites. In both manganese and lithium ferrites the orbital electron contributions to the ionic moments are small, and it follows from the above that the magnetocrystalline anisotropy energies are small in both cases. At first sight it would therefore appear that the permeabilities of both lithium and manganese ferrites should be comparable. However, it is observed that the permeability of manganese ferrite (μ approximately 400) is about ten times that of lithium ferrite (μ approximately 40). The reason for this difference is revealed by studying the influence of a magnetic field applied to lithium ferrite during its cooling from high temperature; the permeability measured along the field direction drops to a value of 9. The interpretation is that in lithium ferrite there are additional forces, inhibiting the rotation of the ionic magnetization vectors, which arise from dipole–dipole interaction. When the field is applied during cooling, the interaction is between lithium ion pairs aligned along the field direction.

In sum, the paper fully justified Dr. Gorter's claim that by adopting careful manufacturing techniques and applying sound theoretical principles, it is now possible to produce ferrite materials of predictable properties and suitable for a wide range of applications.

The final paper of the session was presented by Dr. A. Edwards, of James Neill and Co. (Sheffield), Ltd. Dr. Edwards first dealt with the historical development of the Sheffield magnet steel industry. The most modern and most efficient product of this industry is an alloy prepared by special cooling techniques to have a columnar structure with crystallites having axes of easy magnetization lying along a common direction. The composition of this alloy, known as 'Columnar', is adjusted so that valuable anisotropic magnetic properties are obtained by cooling the completed magnet in a magnetic field. It was pointed out that although the Sheffield permanent magnet tradition is based on alloy steels, it is realized by some manufacturers that future development may well be into the field of ferrite or shaped micropowder magnets. As an example of this trend in Sheffield, brief reference was made to the progress which has been made in the preparation of the anisotropic material $BaO.(Fe_2O_3)_6$; although it has been found difficult to obtain consistently high values of stored magnetic energy with this material, many production problems have recently been solved.

The second part of Dr. Edwards's paper was devoted to an account of some of the very many practical applications of permanent magnets. This was illustrated by a number of well-chosen and most efficiently presented demonstrations, all of which were greatly appreciated by the audience. Outstanding among the applications considered were the automatic train control system using permanent magnets, now installed on the King's Cross–Grantham line, and the hysteresis motors with very small permanent magnet rotors for operation at speeds of 10,000 rev./min. and above.

PLASTIC THEORY OF STRUCTURES

CAMBRIDGE SYMPOSIUM

A RECENT book review ("Plastic Behaviour and Design of Steel Frame Buildings", *Nature*, August 4, p. 227) gave some account of the advances which have been made since the War in the theory of structures, particularly in the plastic design of steel structures. Much of this work has been carried out in the Cambridge Engineering Laboratory. It was fitting, therefore, that the first symposium on the subject in Britain should be held there. One hundred and ten engineers and applied mathematicians, nine from the United States, five from Holland and representatives from the U.S.S.R., Belgium, India and Italy watched, in the introductory session, after dinner in the hall of Clare College on September 18, experiments carried out by Prof. J. F. Baker on three steel structures loaded to collapse. These experiments showed some of the advantages of basing design on plastic behaviour.

During the next three days, eight working sessions were held. The first paper, introduced by Dr. J. Heyman, dealt with the plastic design of single-story portal frames. These have been of particular importance in the development of plastic theory, and a consideration of their behaviour forms a useful introduction to the subject. After dealing with some simple cases, Dr. Heyman turned to the multi-bay frame in which collapse is usually confined to the end bay only. If a horizontal tie is introduced at eaves-level, or the end stanchions are made so stiff that horizontal 'sway' movement is prevented, other interesting modes of collapse under unsymmetrical load and an instability mode may be introduced. Though a separate session had been set aside for the discussion of instability, the subject loomed large in this first session and not unnaturally became the recurring theme of the whole symposium. Mr. A. Bolton complained that the effect of axial load in the rafters was usually neglected and presented calculations showing that considerable reduction in load-carrying capacity would result if the rafter carried an axial load as low as one-tenth its Euler crippling load. This led to a discussion of the effect of cladding on the behaviour of shed buildings. Mr. R. L. Ketter, of Lehigh University, where a research team is working on plastic design, showed a series of curves from which could be read the sizes of members required for a wide variety of shed buildings. This approach appealed to some of the consulting engineers present.

The second paper, introduced by Dr. M. R. Horne, dealt with multi-story frames, in particular with that most complex problem, the behaviour and design of continuous stanchions. The paper considered only those frames where horizontal sway is prevented by the cladding, and showed the state of knowledge of stanchion behaviour and the resulting methods of design available at the moment: namely, to design the beams of the structure to remain elastic, allowing the stanchions to enter the plastic range, or to design the beams plastically while the stanchions are so proportioned as to remain elastic at the collapse of the beams. The discussion began with the description by a practising engineer of a method of analysis based on an assumed initial curvature which he had found confirmed by the early Cambridge tests on stanchions. This was an attempt at an empirical solution, following the kind of reasoning used to-day in elastic design; but it was decided that there is, as yet, insufficient justification for its acceptance. The discussion then turned to the dangers of sway instability, that is, the possibility of the frame as a whole becoming unstable even though the individual members had not reached full plasticity. It seemed to most of the members of the symposium that this was not a real danger for buildings of the type and height usual in Britain, but would become important if brick panel walls were replaced by the metal cladding which is becoming common in America. More attention must clearly be given to the problem as the plastic method is developed for multi-story structures. Attention was directed to the four-story wing of the Engineering Department at Cambridge now under construction and visible from the symposium room, which had been designed plastically—sway collapse fortunately being prevented by its attachment to the main building.

The third session was devoted to the subject of foundation design, with an introductory paper by K. H. Roscoe and A. N. Schofield. One of the attractions of the plastic method of designing a steel frame is that it allows a rational approach to be made also to the design of foundations. It is usually desirable, so far as the superstructure is concerned, to fix the feet of the stanchions. Orthodox elastic design virtually demands the assumption, in such a case, that the feet are completely encastré, so that no rotation or sinking can occur. It is, of course, impossible to build foundations which satisfy this assumption. The plastic design of the framework is unaffected, however, by sensibly large rotations or sinking of the foundations, so long as the full plastic moment of the steel stanchion can be developed. The Cambridge team has carried out full-scale tests on steel shed buildings with real, and most economical, foundations which confirm this. Plastic theory can also be applied to the design of the foundations themselves, and it is common to assume the soil to be a dilatant perfectly plastic material. It is interesting, as indicating how far the principle of plastic design for the steelwork had been accepted by the audience, that the lively discussion was centred almost entirely on the design of the foundations. The merits of pad and pier foundations for eccentric loads were compared, together with the advantages of tieing the latter and the practical difficulties of so doing. It was remarked that when excavating the soil after failure around the pier foundations, in the tests mentioned above, a layer of loosened soil into which the fingers could be inserted was evident to a depth of 2 ft. between the moving soil wedge and the surrounding soil. The thickness of these dilatant layers was so small in any form of laboratory or model test that they could not easily be measured or even observed.

The fourth session was opened with an elegant paper by Prof. W. Prager, of Brown University, on plastic design and thermal stresses. The work was based on an idealized moment curvature relationship applied to a propped cantilever introducing also the concept of standard states of bending moments. This particular problem allows of graphical representation but leads to general theories which can be proved rigorously. It was found that shakedown would occur if, and only if, a state of self-stress could be found such that superposition of the elastic response to the prescribed cycles of load and temperature on this state of self-stress nowhere led to a violation of the yield condition. It was suggested in the paper that alternating plastic deformation must be avoided at all costs. Discussion revealed evidence that in many steels tens of thousands of cycles are necessary to produce failure under this condition, so that in many practical cases it may be unobjectionable. An incremental collapse mechanism involving large changes of geometry might, on the other hand, be objectionable. The discussion turned again to problems of instability. Attention was directed to the case of a plate subjected to lateral load where compressive stresses led to buckling. Prof. Prager remarked that compressive stresses in themselves did not upset the plastic theory, but that if buckling occurs then some modification has to be made. It was pointed out that buckling due to heating and due to loading are quite different effects and that incremental collapse cannot be produced by thermal cycles alone. Some loading of the structure is necessary for this mode of collapse, but thermal stresses alone can produce incremental buckling.

The session dealing with impact was introduced by two very different papers, "Dynamic Loading and Impact", by Prof. Paul S. Symonds, of Brown University, and "Simple Experiments on the Dynamic Plastic Behaviour of Mild Steel Beams", by Dr. E. W. Parkes, of Cambridge. Prof. Symonds has attempted to replace the structure, subjected to such impact loading as a severe blast pressure, by a model of one degree of freedom, when the structure in fact would undergo a highly complicated series of shape changes that would require many degrees of freedom in an accurate description. Dr. Parkes described experiments he has carried out to find how structures behave when struck by moving masses. He found that, except at the point of impact of a high-velocity projectile, their deformations could be predicted by analysis based on the concept of a constant dynamic plastic moment. There was much discussion on how far the elastic response of a structure could be neglected and on the influence of high rates of straining on the yield. It was pointed out that the simple plastic theory leads to a simple and most reliable design method for structures under impact when the rates of straining are not excessively high. A demonstration showed how the once familiar 'Morrison table shelter' behaved, and a film illustrated the success of an even earlier war-time application of the plastic method to the design of reinforced surface shelters. The hope was expressed that the results of the vast amount of experience obtained in Britain during the War had been made available to American workers.

While discussion on various aspects of instability kept recurring throughout the Symposium, one session was devoted entirely to the subject. W. Merchant, of the Manchester College of Technology, had provided in an introductory paper a study of the behaviour of a structure which fails by a combination of plasticity and instability, using some of the early Cambridge strut tests as an illustration; but in opening the discussion he turned immediately to the possibility of overall instability in a multi-story frame in which sway bracing of one form or another was not present. As in the second session, this gave rise to much discussion and a certain feeling of pessimism. Accounts were given by Dr. R. H. Wood of the Building Research Station and others of particular problems which have been solved exactly, the labour involved being excessive; but though Mr. Merchant suggested some interesting empirical approaches, it became clear that this is a branch of the subject which requires more study. Among other problems discussed was the lateral instability of I-beams. It appeared from Prof. B. Thurlimann's account of work at Lehigh that the broad-flanged beam is not as satisfactory in this respect as the British Standard section. Dr. M. R. Horne gave an account of how design rules have been evolved to guard against the danger of lateral instability in plastic designs using British Standard sections.

The seventh session was devoted to design problems and was opened by Dr. M. R. Horne and Dr. J. Heyman with a paper raising some of the practical problems encountered by the Cambridge team in producing the first plastically designed structures. Slides were shown of a number of these buildings, including a seventeen-bay factory building, an unusual monitor-type portal frame workshop and the British Welding Research Association's fatigue laboratory, which was the first plastic building. This encouraged others to show their designs. Mr. R. T. Cole, who has used the plastic method for some hundreds of structures, claimed that bolted connexions can be satisfactorily introduced, are attractive architecturally and are cheaper than site-welded connexions. He was challenged on this last point, as certain firms insisted on the site-welding of their structures because it gave the lowest erection costs. There was much discussion on the problem of deflexion in plastically designed structures. Engineers were urged to publish accounts of the structures they designed plastically, as only in this way can experience be passed on quickly and the more timid encouraged to use rational methods.

The final session dealt with the teaching of the plastic theory of structures and its place in the university curriculum. Prof. J. F. Baker made it clear that, while he is enthusiastic about the subject, particularly as it is the only satisfactory way structural design can be taught in a university, he would not introduce it into the engineering syllabus unless something else could be left out. This naturally led, in the vigorous discussion which always arises when teaching problems are ventilated, to the question of what can be left out of to-day's crowded syllabus. The conclusion reached was that in an undergraduate course on theory of structures, a sound grounding in the fundamentals makes it possible to omit many of the specialist methods of elastic stress analysis. Stability again came to the fore; one experienced teacher, putting in a plea for its consideration, pointed out that he was not committed to any particular theory. He regarded all theories as tools of analysis, so that a student should be capable of dealing with problems of elasticity, plasticity and stability. Other topics discussed were the possible use of models in teaching and the behaviour of flat plates, the last arising from an illustration used by Prof. Prager to show there is no satisfactory method of elastic design.

At the end of the session Prof. Symonds, after dealing with the teaching at Brown University, remarked on the high level of interest and the high standard of discussion which had persisted throughout the three days of the symposium. Mr. T. R. Higgins, secretary of the American Society of Steel Construction, who had presided over this last session, expressed surprise at the level of familiarity with the subject shown by such a large group of practising engineers, He said that it is a new subject for American engineers, who are not so far ahead with it as are designers, in Britain.

There is no doubt of the unusual interest throughout the symposium. Plastic design, which enables so many of the unsatisfactory assumptions of elastic theory to be swept aside, has captured the imagination of most teachers and of many practising engineers. While there is little evidence that the great body of structural designers are aware of the revolution in their art, plastic design is clearly spreading fast.

OBITUARIES

Dr. J. W. Trevan, F.R.S

Dr. J. W. Trevan was well known as a pharmacologist and as a pioneer of the biological testing of drugs. He died on October 13 last at the age of sixty-nine. He was born in Bodmin and after education in Plymouth he gained scholarships to St. Bartholomew's Hospital, London, where he obtained several prizes and graduated in physiology in 1908 and in medicine in 1911. After undertaking resident appointments, he obtained the Fishmongers' Research Scholarship and carried out research on respiration. In 1914, he qualified as M.R.C.P. and served in the First World War as a pathologist.

Trevan joined the Wellcome Physiological Research Laboratories at Beckenham in 1920; later he became a member of the Standards Commission of the League of Nations, and was elected president of the Section of Therapeutics of the Royal Society of Medicine. In 1940 he became director of the Wellcome Physiological Research Laboratories and a director of the Wellcome Foundation, Ltd. In 1942 he became a Fellow of the Royal College of Physicians and in 1946 a Fellow of the Royal Society.

At Beckenham Trevan worked at first on local anæsthetics and analeptics, and on chemotherapy. He had great ability in the design of apparatus, and the simple and useful microbalance and microsyringe which are now very commonly employed were his inventions. Soon his attention was attracted to the difficulty of biological standardization of digitalis, and later of insulin. Up to that time, no one had realized that one animal differed very greatly from another similar animal of the same species in its response to drugs. Trevan's work emphasized the necessity for the use of a large number of animals for the standardization of drugs and he introduced the term *LD*50 for the dose of drug which would kill 50 per cent of the animals under test. Much of his work was directed to the standardization of insulin; there were great difficulties in this matter as the early batches of insulin varied considerably from one to another and clinicians were unable to depend on a constant preparation. His work resulted in the development of a very satisfactory method of standardization using a quantal method depending on the convulsions induced in batches of mice. This work provided for a test for insulin which enabled the clinician to rely on every batch being of the same potency, and it was a considerable contribution towards the solution of the problem of the treatment of diabetes.

His work on the bioassay of drugs was published in the *Proceedings of the Royal Society* in 1927; it was the forerunner of the statistical methods of drug standardization which are in common use to-day, enabling us to make an accurate assessment of the error of a particular test. These assays are of fundamental importance, both to the manufacturer of therapeutic substances and to the physician who is making use of the preparations.

Trevan was one of the most friendly and helpful of colleagues, and his great scientific ability was devoted as much to helping his associates and subordinates as to his own research. While he was a great enthusiast in all scientific matters, he was much more critical of his own work than that of his colleagues, and his notebooks contained great numbers of records of carefully controlled experiments which he did not feel were sufficiently significant for publication. He had a great sense of humour and delighted in telling stories against himself; the many honours he received he always felt were quite undeserved.

While so many workers in the field of pharmacology have gained much of his advice and foresight, such was his modesty that he usually managed to make them feel that they had thought of the ideas themselves. He was a pioneer in pharmacology, especially in the field of the standardization of drugs, and there are many who will miss his friendly advice and help.

He was a deacon and member of the choir at St. Aubyn's Congregational Church at Upper Norwood. His first wife, daughter of the Rev. J. L. Keyes, died in 1937. Of this marriage there were three sons and two daughters. His second wife, by whom he had three children, is the daughter of Sir Hubert Llewellyn Smith.

G. A. H. Buttle

Prof. Arthur Rohn

A year ago mention was made in these pages of the first centenary of 'ETH', as it has come to be internationally known, namely, the Eidgenössische Technische Hochschule, Zurich, or the Swiss Federal Institute of Technology. Now we have to record the death on October 3 of the man who more than any other in his generation helped to give the Institute the position it holds as a centre of teaching and research in the field of technology in the widest sense of the term: Prof. Arthur Rohn, former president of the Institute's board and rector as well as a member of the professorial staff during eighteen years.

In the twenty-two years from 1926, when he was appointed head of the Institute, until 1948, when, greatly admired and respected as one of the country's élite, he gave his farewell address, Prof. Rohn had determined the policy and guided the development of the Institute in a way that earned him the gratitude of scholars, students and industrialists all over the world. His greatest achievement is the creation of more than two dozen specialized research centres in the form of institutes, which he helped to provide with sufficient grants, libraries, staff and special buildings. In addition to this, he persuaded the Swiss Government to create forty new professorial chairs in the field of pure and applied science. If the research institutes, for example, of aerodynamics, town and country planning, industrial accountancy, bear witness to his far-sighted vision, other innovations, like the new chairs for theoretical physics and mathematics, show his insistence on solid basic research in fundamentals.

Before he was called to the post of president of the Institute's Board, Prof. Rohn had held for nearly twenty years (1908–26) one of the most important chairs of civil engineering, that of structural engineering and bridge-building. Early and extensive experience in bridge-building in Switzerland and the Ruhr district had introduced him to this, his favourite field, in which he soon rose to be a master.

It was not only the eminence of the specialist nor the long experience as an academic teacher that enabled Arthur Rohn to exercise his brilliant leadership in higher professional education and industrial development, nor were these the only qualities that earned him the high respect—the veneration even—that was felt for him in later years. He combined qualities that are not often found together in such fullness: breadth of vision with practical executive power and great firmness of will, a profound belief in the capacity of men to improve things, with a clear notion of what was possible, aristocratic aloofness with kindness and generosity and a sense of justice. It was this largeness of his mind and the impressive stature of his moral character that won him the admiration of his students and that inspired the Institute of which he was for so many years the head.

Max Wildi

V. A. Obruchev

Vladimir Afanasievich Obruchev, the premier geologist in Russia, died in Moscow on June 19, at the age of ninety-three. He was born on September 28 (Old Style), 1863, in Klepinino, Tver district, in the family of an army officer. He was educated in Vilna, and went to the St. Petersburg Mining Institute. After graduating as a mining engineer in 1886, he went to Central Asia where, following the lead of his teacher, Prof. I. V. Mushketov, he spent two years in the study of aeolian deposits. In 1888 he was attached to the Mining Department in Irkutsk.

This was the beginning of Obruchev's work on the geology of Siberia, to which he devoted the rest of his life. At first he worked on the stratigraphy and tectonics of the Palæozoic and Pre-Cambrian rocks of the Transbaikal and Lena region, and studied the geology of the gold fields. In 1892 he started on a series of travels to Central Asia, Dzungaria, Mongolia, China and various parts of Siberia. For a time he taught geology in Tomsk Polytechnical Institute (1901–12) and later in Taurida University at Simpheropol (1918–22) and in the newly founded Moscow Mining Academy (1922–28). In 1929 he was elected to the Academy of Sciences and during 1929–34 he was the director of the Geological Institute of the Academy. There are many other administrative and editorial posts which he filled at different times in his career.

Obruchev's publications are very numerous and they range over a wide field. His most important work deals with the geology of Siberia, on which he was a recognized authority. The three fundamental works on this subject are: "The Geology of Siberia", in one volume (1926), published both in Russian and German ("Geologie von Siberien"); "The Geology of Siberia", in three volumes (1935–38); and "The History of the Geological Explorations of Siberia", in five volumes (1931–42). The two best-known text-books written by Obruchev are: "Ore Deposits" and "Field Geology". His travel books include: "Central Asia, Northern China and Nan-Shan", "From Kyakhta to Kuldzha", "In the Mountains and Deserts of Central Asia", and "My Travels in Siberia". But even more popular were Obruchev's novels, all of them provided with a vivid geological setting, such as "The Land of Sannikov", "Gold-seekers in the Desert", and "Plutonia".

Obruchev, in the eyes of his contemporaries, was not only a great geologist, a great traveller and a great writer; he was also a man of striking personal charm, a remarkable organizer and a great character. He was very popular, especially with the young readers of his popular books and novels; it was said of him that he used to receive thousands of letters, and that none was left unanswered when an answer was asked for.

S. I. Tomkeieff

Mr. D. L. Edwards

With the death on September 23, after a brief illness, of Mr. D. L. Edwards, director of the Norman Lockyer Observatory of the University of Exeter for nearly twenty years, another link with Sir Norman Lockyer, eminent astronomer and founder and editor for many years of *Nature*, has been severed all too soon.

Donald Luther Edwards was born at Peterborough on January 11, 1894, into a family whose scientific attainments were later to receive distinguished recognition in the fields of entomology and geology. He was educated at Cambridge County School, and the Royal College of Science, London, whence he graduated with the associateship, and a diploma in astronomy.

On the outbreak of the First World War he joined the Signals section of the Royal Engineers, serving in France with a sound-ranging unit. After demobilization early in 1919, Edwards went to Sidmouth as assistant to Lockyer, and commenced his duties at the Hill Observatory (as it was then called) in May of that year. Sir Norman died in 1920; and with the appointment of his son, Dr. W. J. S. Lockyer, as director in February 1921, Edwards became chief assistant, which post he held until December 1936, when he, in turn, was made director following the death of Dr. Lockyer.

During the period of his association with the Lockyers, Edwards's main interest lay in the determination of stellar parallaxes by a spectroscopic method first suggested by Adams in 1920. At Sidmouth, the technique was successfully applied to objective-prism spectra; and between 1922 and 1930 six papers were published by him, summarizing the results for two hundred B-type stars.

Later researches continued the study of the irregular variable, γ Cassiopiae, begun in 1923 by W. J. S. Lockyer. Quite recently, he had contributed an essay on this star to the second of the commemorative volumes, "Vistas in Astronomy", presented to Prof. F. J. M. Stratton on his seventieth birthday.

As director, he had the future development of the Observatory always at heart, while preserving the best of the Lockyer tradition. It was due largely to his untiring efforts that the Observatory Corporation was transferred to the University of Exeter (then the University College of the South-West) in May 1948.

Edwards was elected a Fellow of the Royal Astronomical Society in 1921 and served on its Council during 1946–50; he was also a member (from 1915) of the British Astronomical Association.

In all that he undertook he was conscientious and meticulously careful in every detail. Outside his professional work, his interests were wide, embracing such diverse subjects as music, ornithology, Egyptology and philately. For almost forty years he had known the encouragement and support of a serenely happy domestic life, having married in 1919 Elsie, daughter of the late Thomas Stanley, of Wednesbury, who survives him.

D. R. BARBER

NEWS and VIEWS

Chemical Engineering at the Imperial College, London: Prof. P. V. Danckwerts

A CHAIR of chemical engineering science has been established in the Department of Chemical Engineering at the Imperial College of Science and Technology, London, and Mr. P. V. Danckwerts has been recently appointed to it. Mr. Danckwerts studied chemistry at Balliol College, Oxford, under Mr. R. P. Bell. Graduating in 1939, he spent a year as a research chemist with the Fullers' Earth Union before joining the Navy. He served for six years, first as a bomb-disposal officer in various parts of the world, then, after being wounded during the invasion of Sicily, at Combined Operations Headquarters. At the end of the War he went as a Commonwealth Fund Fellow to study chemical engineering at the Massachusetts Institute of Technology, and received a master's degree in chemical engineering practice in 1948. He then joined the staff of the newly formed Department of Chemical Engineering at Cambridge, where he spent the next six years as a demonstrator and lecturer, helping to establish the curriculum and set the standards for the Chemical Engineering Tripos course. He also made a number of theoretical contributions to chemical engineering science in the fields of diffusional processes, mixing and continuous-flow systems. For the past two years he has been deputy-director of the Research and Development Branch of the Industrial Group, Atomic Energy Authority, where his duties have included the direction of the Group's extensive development work in chemistry and chemical engineering.

Senior Appointments at the Royal Aircraft Establishment: Mr. E. C. Cornford

MR. E. C. CORNFORD has been appointed head of the Guided Weapons Department of the Royal Aircraft Establishment. He was educated at Kimbolton School and Jesus College, Cambridge, where he read mathematics, graduating in 1938. He entered government service at the Royal Aircraft Establishment, where he was concerned with research on armament problems. During most of the war years he worked with the late Dr. L. B. C. Cunningham in the Air Warfare Analysis Section of the Air Ministry at Harrow. His work covered a wide range of theoretical investigations in the growing field of operational research, the application of mathematical probability methods to problems of air combat, and the introduction of the new radar blind-bombing devices which were so successfully used by Bomber Command. In 1946 he was transferred to the newly formed Controlled Weapons Department at Farnborough. After attending the Joint Services Staff College in 1950 he was seconded as senior principal scientific officer to the Scientific Adviser's Staff, Air Ministry. He returned to the Royal Aircraft Establishment as superintendent of the Guided Weapons Assessment Division in 1954 and has since been responsible for advanced work in the study of new weapon systems and air defence problems.

Mr. D. J. Lyons

MR. D. J. LYONS has been promoted deputy chief scientific officer to fill the post of senior superintendent, Ballistic Missile Division, in the Guided Weapons Department at the Royal Aircraft Establishment. He is a graduate of the University of London (Queen Mary College), where he obtained his degree in engineering in 1937. Following this, he joined the Aerodynamics Department at Farnborough, where he worked on wind-tunnel and full-scale stability and control problems. He had an interval of two years on flying duties in the R.A.F. before returning to Farnborough in 1941. Afterwards his work covered full-scale investigation of stability problems in new aircraft, particularly on spinning and autostabilization, followed by a move to the Guided Weapons Department, where he took charge of the Division responsible for experimental projects, control physics and missile aerodynamics. He has for several years specialized in problems relating to ballistic missiles.

Mr. P. A. Hufton

MR. P. A. HUFTON has been appointed senior superintendent of the Supersonics Division of the Aerodynamics Department, Royal Aircraft Establishment. He was educated at the University of Manchester, graduating in 1933 in engineering. After obtaining his M.Sc. for postgraduate research on flow through labyrinth packing, he joined the Royal Aircraft Establishment in 1934. A period on wind-tunnels was followed by some years on aerodynamic research in flight. He built up and led a strong team dealing with the handling and performance aspects of take-off and landing and low-speed flight. He moved to the Aircraft and Armament Experimental Establishment at Boscombe Down in 1946, as one of the superintendents, and did much to establish revised methods of performance testing and handling assessment for the new types of aeroplane then emerging, his knowledge being used extensively both by the civil and military authorities. Returning to the Royal Aircraft Establishment in 1953, he took charge of the supersonic aerodynamics group at Farnborough, at a time when supersonic flight was rapidly mounting in importance, and this has now been followed by his new appointment as head of an expanded Supersonics Division of the Aerodynamics Department.

Automation and Technical Education

A DEBATE on automation in the House of Lords on October 23 was opened by Lord Macdonald of Gwaenysgor, who emphasized the importance of research and of technical training, as also did Lord Crook; Lord Hall suggested that overhaul of training systems in Britain is urgently required. Lord Hailsham replied to the debate on behalf of the Government. He emphasized that clear-sighted planning, in direct consultation with the workers, is essential if automation is to avoid creating hardship; this is primarily the responsibility of management. He sees no reason why the consequences of the introduction of automatic machinery cannot be forecast far enough ahead for the individual employer to make his plans for recruitment and re-training his labour force, and to discuss well in advance with representatives of the workers how they will be affected. The Minister of Labour intends to discuss with representatives of employers and trade unions the period of notice in the contract of service and its relation to the length of service previously enjoyed, and has powers to assist transfers and training. In regard to education, Lord Hailsham strongly emphasized the impact which will be made upon the whole educational system of Britain, particularly on general education. It is still insufficiently appreciated that this is the real basis. Parents still do not realize the value of a technical secondary education, although there is increasing need for more craftsmen and technicians of all kinds and for new and modified types of training, and—most important of all—for more technologists and managers. Of non-recurrent grants of more than £25 million allocated by the University Grants Committee since the War, about one-third has gone to general university buildings of interest to all faculties, and 84 per cent of the remainder has gone to laboratories and other buildings for research and teaching in science and technology, including medicine. In regard to research, Lord Hailsham said that while the money provided under Conditional Aid Funds has come to an end, the continuation of the studies scheduled in the report on automation is receiving close attention, and it should not be assumed the work will come to an end.

Replying to a question in the House of Commons regarding progress in the extension of facilities for technical education since the publication of the White Paper, Sir David Eccles said on October 25 that the 1957–58 and 1958–59 building programmes have been approved and local education authorities know that they can start more than £40 millions worth of the five-year programme of capital investment. Eight colleges have been provisionally designated colleges of advanced technology and two designations confirmed. The National Council for Technological Awards has published its conditions for awarding the diploma in technology. The number of sandwich courses has risen from 103 to 168, and substantial increases of salary, recommended by the Burnham Committee for technical college teachers, have been approved. A committee, drawn from the National Advisory Councils on Education for Industry and Commerce, under the chairmanship of Dr. Willis Jackson, has been set up to report on the supply and training of teachers for technical colleges. The Minister has met representatives of local education authorities about regional co-ordination and inter-authority payments.

Awards for Postgraduate Study in Britain

NEW arrangements for awards for postgraduate study have been announced by the Ministry of Education and the Department of Scientific and Industrial Research, which have recently concluded in consultation with the Committee of Vice-Chancellors and Principals of Universities of the United Kingdom a full review of the present system. From 1957–58, the Department of Scientific and Industrial Research will offer a considerably increased number of competitive postgraduate awards in science and technology. These awards will be of two kinds: (1) *Research Studentships*, for postgraduate students seeking two or three years of supervised training in research, leading in most cases to a doctorate of philosophy; and (2) *Advanced Course Studentships*, for postgraduate students wishing to attend courses of advanced instruction in science and technology of not less than six months duration. The awards will be tenable at technical colleges as well as at universities. Their increased number has been so calculated that it will not normally be necessary for the Ministry of Education nor for local education authorities to make awards for postgraduate study in science or technology. Full details of these awards are being issued by the Department of Scientific and Industrial Research. Present arrangements for awards to students in medicine, dentistry, agriculture and veterinary science are not affected, nor are those for aiding graduates to train as teachers. Applications for the Department of Scientific and Industrial Research awards must be made through university or college authorities, and must reach the Department by March 1, 1957. The Ministry of Education is offering about 250 similar postgraduate awards, to be known as 'State studentships', for postgraduate study in arts subjects.

Chemical Industry in Britain

In his Messel Memorial Lecture to the Society of Chemical Industry on October 12, Sir Alexander Fleck, in reviewing some achievements and problems of the chemical industry, referred briefly to the life and work of Messel himself, particularly to his emphasis on the co-operation of science and industry, his insistence that specialization should be based on general education capable of stimulating the imagination and promoting independent thinking, and on the way he spent his working life at Silvertown living among the people who were employed by him. Sir Alexander suggested that if more employers and leaders had done this, the centres of chemical industry might have been made desirable residential neighbourhoods. He laid some stress in conclusion on this aspect of industry, urging that we cannot afford to make our surroundings either a geographical or a cultural desert, and that there must be sociological advance on many fronts, including a general advance in the educational level and a spirit of sincere service to the community. Sir Alexander also emphasized the need both on the management side and on the trade union side for a more flexible organization, capable of understanding current and impending changes; and while such an organization is being built up, the more intimate partnership of the works councils has an important part to play.

Looking at the achievements of the industry, Sir Alexander put the output of sulphuric acid at 2,095,000 tons in 1955 compared with 800,000–900,000 tons in 1881, and that of soda ash, soda crystals, caustic soda and sodium bicarbonate, which in 1881 was nearly 600,000 tons, probably exceeded 2 million tons in 1951. The output of dyestuffs had grown from 6,950 tons in 1907 to 42,900 tons in 1951. The average five-and-a-half-fold increase in the real value of production over a large section of the chemical industry in Britain between 1907 and 1951 can be compared with a three-fold increase for manufacturing industry as a whole; over the past five to ten years, the expansion for the whole industry was 9 per cent per annum, compared with 5 per cent for manufacturing industry as a whole.

Finance for the Department of Scientific and Industrial Research

Replying to a Parliamentary question in the House of Commons on October 23, Mr. J. R. Bevins, Parliamentary Secretary to the Minister of Works, as representing the Lord President of the Council, said that the five-year plan for the expansion of the activities of the Department of Scientific and Industrial Research provides for a financial review in the event of major variations in prices. This review has now taken place, and, subject to annual votes, additional resources will be made available up to March 1959 for grants to research associations and for other purposes. As the Department's receipts for paid services exceed estimates, it will be possible to maintain the number of awards to postgraduate students and other scientific grants during 1956–57.

University of Oxford

The issue of the *Oxford University Gazette* for October 16 gives some interesting statistics on the numbers in residence in the University and their various lines of study. There were 2,463 matriculations in 1954–55, an increase of nearly 3·7 per cent on the previous year, and for 1955–56 there were 6,207 men and 1,139 women in residence, making a total of 159 more than last year. The distribution of students under the six headings distinguished by the University Grants Committee is as follows, the first figures referring to men and the second to women: arts, 4,501 and 918; science, 1,139 and 163; medicine, 282 and 45; technology, 101 and 1; agriculture, 98 and 4; oversea services probationers, 52 and 1. The numbers of those taking honours schools in scientific or technical subjects in 1956 are as follows: mathematics, 68; physics, 74; physiology, 69; chemistry, 115 (part I) and 77 (part II); zoology, 23; botany, 12; geology, 5; engineering science, 29; geography, 57; agriculture, 9; forestry, 19; psychology, philosophy and physiology, 14; and biochemistry, 5 (part I) and 8 (part II). At Oxford, research students working for either the D.Phil. or B.Sc. in 1956 numbered 218 and 802, respectively. Though the University population is nearly 50 per cent greater than in 1938, the research side has obviously increased to a very much greater extent since then, for the comparable pre-war figures are: D.Phil., 67; and B.Sc., 78.

Statistics in the University of Sheffield

Through the generosity of the United Steel Companies, the University of Sheffield has been able to create an independent Department of Statistics, which began work as such at the beginning of this session. Provision for the teaching of statistics and for research in this field has hitherto been made within the Departments of Mathematics; but the growth of the subject and the very great increase in its use in wide fields of scientific and medical work—which in turn have meant many calls on the University staff in statistics—have rendered it desirable that a separate department should be established. This was already projected as a future development: the action of the United Steel Companies has made it possible to realize it at once. The head of the new Department, a post which carries the rank of senior lecturer in the University, is Dr. G. H. Jowett, hitherto lecturer in statistics in the University, whose post will be entitled "The United Steel Lectureship".

British Museum (Natural History): Recent Gifts

The British Museum (Natural History) has recently received a number of gifts, among which are the following. The Royal College of Surgeons has presented three sub-fossil human skulls from East Africa, thirty-five miscellaneous human skeletal fragments (mainly limb bones), eight models illustrating eruption of human teeth, and one primate brain-cast. Mr. Angus Booth (University College, Achimota, Gold Coast) has presented a large collection (114 specimens) of monkeys from the Ivory Coast, Gold Coast and Togoland, and four schoolboys have presented the considerable part of a skeleton of the rather rare narrow-nosed rhinoceros, *Dicerorhinus hemitoechus* Falconer, which they found in a peat deposit on the foreshore at Selsey, Sussex; further bones have been recovered by officers sent from the Museum, where the remains are being hardened and repaired. The cast of a skull of a child of the Old Stone Age, found with Mousterian flint implements in a cave of Teshik-Tash in Uzbekistan in 1938, has been received in exchange with the Museum of Anthropology, Moscow State University, and casts of the hand and foot bones of an early Neandertal man from Kiik-Koba, Crimea, have been received in exchange from the Institute of Anthropology, Leningrad, and the Museum of Anthropology, Moscow State University. The skull of an early Inca or Pre-Inca individual showing seven trephinations which the owner survived, collected at Pachacamae, in the Department of Lima, Peru, by the late Dr. D. S. Matthews, has been presented by the British Andean Expedition to Mount Huageruncho (1956). An exchange has been arranged with the Meteorite Committee, Academy of Sciences of the U.S.S.R., Moscow, through Prof. E. L. Krinov, by which specimens of ten meteorites hitherto unrepresented in the Museum's collection at South Kensington have been acquired.

Supplies of Anterior Pituitary Hormones

Five of the individual Institutes of the National Institutes of Health, Bethesda, Maryland, are jointly providing the funds for the purchase or production of large uniform lots of anterior pituitary hormones, other than adrenocorticotropic hormone, purified to meet exacting specifications set by the Endocrinology Study Section both for potency and for low limits of contamination with other activities. The first lots of bovine growth hormone and of ovine prolactin have been approved by the Study Section and are ready for distribution. The growth hormone and prolactin are packed as sterile, lyophilized powders in vials of 50 mgm. and 25 mgm. respectively. Data on the estimated potency and degree of contamination, and instructions for dissolving the materials, are issued with each package. A pilot plant at Emory University is being set up under the direction of Drs. Stanley Ellis and Alfred E. Wilhelmi for the production of follicle-stimulating, luteinizing and thyrotrophic hormones. These materials will not be ready for some months. Grants of the hormones will be made to qualified investigators who apply to the Endocrinology Study Section, c/o National Institutes of Health, Bethesda 14, Maryland. Application may be made by letter giving a brief description of the proposed work, together with an estimate of the amount of hormones required. It is hoped that by this service both clinical and fundamental studies on the anterior pituitary hormones will be stimulated.

The Mond Magazine: a Journal on Products from Nickel-containing Ores

For a quarter of a century the *Nickel Bulletin*, published by the Mond Nickel Co., Ltd., has provided a monthly summary of the world's literature relating to nickel and nickel-containing materials. The Company has now instituted the publication of *The Mond Magazine*, which is intended to have a wider scope and different functions, though it will not, fortunately, supersede the *Bulletin* itself. The object of the new publication is to provide articles and notes on a wide variety of subjects related to all the products extracted from the Sudbury ores, which, in addition to the nickel, contain copper, cobalt, gold, silver, the platinum metals, selenium, tellurium, sulphur and iron ore. In the first issue (No. 1, July 1956; pp. 24) are articles on terramycin, the plant for which is constructed of a nickel–chromium corrosion-resisting steel; a short note on palladium in relation to its use in jewellery; stained-glass windows, in which cobalt, selenium and nickel, etc., are used as colouring matters; nickel–chromium steels in steering-rod assemblies; high-nickel cast iron; the use of nickel–chromium–molybdenum steel in the oxygen equipment for the 1955 Kangchenjunga expedition; the resistance of platinum to molten glass; and mechanical excavators. It is clear that this new publication, which can be obtained free of charge from the Publicity Department, Mond Nickel Co., Ltd., Thames House, Millbank, London, S.W.1, should interest a very wide variety of new readers.

Prehistoric Wooden Implements from Africa

Besides a note by Dr. A. S. Brink on some Thecodonts, Part 6, Vol. 1, "Researches of the National Museum, Bloemfontein", contains an interesting article by Dr. Desmond Clark on a wooden implement from the level of Peat I at Florisbad, Orange Free State. Florisbad is not a very satisfactory site. There are peats of various ages at these fossil springs, and when, as in 1912, local upheavals occur, their contents all tend to get mixed up. However, all the levels seem to be referable to some time in the Gamblian period. It is rare for wooden objects to have survived from prehistoric times. Only in exceptional circumstances can this occur. Dr. Clark, however, has himself unearthed an even more interesting example at a site (Kalambo) near Abercorn in Northern Rhodesia. Here the date is definitely late Acheulean. In both cases the working is of a simple order and not in itself of much importance; but the use of wood by very early man for tool-making purposes is now definitely established.

Bassi's "Del Mal del Segno"

To mark the centenary of the death of Agostino Bassi (see *Nature*, 177, 255; 1956), the University of Pavia has issued an attractive photographic-offset facsimile of the two parts of Bassi's monograph, "Del Mal del Segno" (1835, 1836). Loosely inserted is a brochure in which a note on the commemorative edition by Antonio Pensa is followed by a reprint of the appreciation of Bassi by G. B. Grassi from the collected edition of Bassi's works published in 1925, a list of the changes Bassi made in the second edition (1837) of "Del Mal del Segno", and a catalogue of Bassi's writings. A limited number of these facsimiles are for sale. Inquiries should be made to the Rector of the University of Pavia, Italy.

Royal Society Antarctic Expedition

The main party of the Royal Society Antarctic Expedition for the International Geophysical Year (July 1957–December 1958) under the leadership of Colonel Robin Smart will leave London on November 15 for Royal Society Base, Halley Bay, in the M.S. *Magga Dan*, which is being shared with the Trans-Antarctic Expedition. The party will relieve the advance party of ten men under the leadership of Surgeon Lieut.-Commander D. Dalgliesh who sailed from Southampton in November 1955 in the M.V. *Tottan*, and most of them will remain at Halley Bay until January 1959.

Oversea Service Division, Colonial Office

The following appointments have recently been made in the Oversea Service Division, Colonial Office: J. M. Arthurs (rural education officer, Federation of Nigeria), principal of the Farm Institute, Arapai, Uganda; D. R. N. Brown (assistant director of agriculture, Uganda), deputy director of agriculture, Uganda; V. E. M. Burke (assistant agricultural officer, Kenya), agricultural officer, Kenya; L. F. Derraugh (senior agricultural officer, Gold Coast), commissioner for food products, Department of Agriculture, Gold Coast; E. W. Findlay (agricultural officer, Eastern Region, Nigeria), senior agricultural officer, Eastern Region, Nigeria; J. O. I. Longe (senior agricultural officer, Western Region, Nigeria), principal of School Agricultural Department, Western Region, Nigeria; R. F. A. L. Reed (principal of School Agricultural Department, Western Region, Nigeria), assistant director of agriculture, Western Region, Nigeria; E. Quist-Arcton (assistant conservator of forests, Gold Coast), senior assistant conservator of forests, Gold Coast; J. R. L. Bain (forest assistant Nyasaland), principal forest assistant, Nyasaland; K. H. Bryant (senior assistant conservator of forests, Federation of Malaya), conservator of forests, grade B, Federation of Malaya; C. Cairns (conservator of forests, grade B, Federation of Malaya), conservator of forests, grade A, Federation of Malaya; Foggie, A. (deputy chief conservator of forests, Gold Coast), chief conservator of forests, Gold Coast; J. M. Ramsay (senior assistant conservator of forests, Gold Coast), conservator of forests, Gold Coast; A. Ginsberg (veterinary officer, Kenya), senior veterinary officer, research officer (hygiene), Kenya; L. S. Pfob (veterinary officer, Uganda), senior veterinary officer, Uganda; P. T. Preston (veterinary officer, Kenya), provisional veterinary officer, Kenya; E. A. Wells (veterinary officer, Uganda), senior veterinary officer, Uganda.

Announcements

Prof. Charles Singer and Mrs. Singer have been awarded jointly the George Sarton Medal of the History of Science Society. The Medal was founded last year and the first award was to Sarton himself.

Robert Roesler de Villiers Awards of the Leukemia Society, Inc., have been made to Dr. L. O. Jacobson, professor of internal medicine in the University of Chicago, "in recognition of his pioneer experiments on the beneficial influence of local tissue shielding on general hematologic recovery after external irradiation—a fundamental discovery concerning a therapeutic weapon of continuing value in human leukemia"; and Dr. John F. Loutit, director of the Medical Research Council Radiobiological Research Unit at the Atomic Energy Research Establishment, Harwell, "in recognition of his elegant and conclusive demonstration that general hematologic recovery after total body irradiation is enhanced by bone marrow cell colonization, even from a different species—a discovery of potentially great significance in the therapy of human leukemia".

It is announced by the University of London that the title of reader in sociology has been conferred on Dr. R. T. McKenzie, and that of reader in industrial relations on Mr. B. C. Roberts, in respect of the posts held by them at the London School of Economics and Political Science.

The following have been elected officers of the Association of Clinical Biochemists: *President*, Prof. E. J. King; *Chairman*, Dr. R. Gaddie; *Treasurer*, Dr. I. MacIntyre; and *Secretary*, Dr. A. L. Tárnoky (Royal Berkshire Hospital, Reading).

Some time ago (*Nature*, 175, 1066; 1955) reference was made to the "Coffee Pot", a club for young university graduates and professional people founded by Mrs. H. D. R. P. Lindsay. To meet the many applications, Mrs. Lindsay has now started a second club, the "Samovar", which has the use of the restaurant of the "Coffee Pot". Inquiries about the club should be made to the Membership Secretary, The Samovar Club, 108 Baker Street, London, W.1.

The British Society of Rheology is organizing a conference on "Rheology of Elastomers" to be held at the Rubber Producers Research Association at Welwyn Garden City during May 30–31. Further information can be obtained from the Honorary Secretary of the Society, 52 Tavistock Road, Edgware, Middlesex.

The Metallurgical Engineering Committee of the Institute of Metals is arranging an all-day informal discussion on "Degreasing", which will be held in the University of Birmingham on February 27. Members and non-members who would like to be present should notify the Secretary of the Institute of Metals, 17 Belgrave Square, London, S.W.1.

The annual exhibition meeting of the Botanical Society of the British Isles will be held in the Lecture Hall, British Museum (Natural History), on November 24, from 2.30 until 5.30 p.m. Further information can be obtained from Dr. J. G. Dony, 41 Somerset Avenue, Luton, Beds.

A small exhibition is being held in the University of Cambridge Engineering Department and will be open until November 17 to commemorate the publication of Sir Henry Bessemer's paper to the British Association entitled "On the Manufacture of Malleable Iron and Steel without Fuel". Exhibits include a showcase of original Bessemer steel specimens made between 1856 and 1859, lent by the Iron and Steel Institute; modern examples of steel made by the Bessemer acid process given by the Workington Iron and Steel Co.; a model of a Bessemer plant lent by the director of the Science Museum; a film strip projector automatically showing diagrams of the Bessemer converter in action; and photographs, notes and diagrams.

The Foundations' Fund for Research in Psychiatry has been given a grant of 3,682,000 dollars by the Ford Foundation for the support of the development of research personnel in mental health. It is stipulated that the money be expended or committed within five years, and it will be used concurrently with the present programme of fellowships and research grants in the field of psychiatry and related sciences. A brochure describing such awards can be obtained from the Foundations' Fund for Research in Psychiatry, 251 Edwards Street, New Haven 11, Connecticut.

Full-time courses on "Radioisotopes and Their Uses" are being arranged in the Department of Chemistry, Sir John Cass College, Jewry Street, Aldgate, London, E.C.3. These courses, which begin on January 14, are each of four weeks duration, and are a development of evening courses in radioactivity and radiochemistry established at the College in 1949. Additional facilities have been provided, and a new instrument room has been equipped for measurements and counting. Entry is restricted to graduates or others possessing an equivalent professional qualification. The fee for each course is £30.

The Wellcome Trustees announce that the office of their chairman (Sir Henry Dale) and their scientific secretary (Dr. F. H. K. Green) has been transferred from 24 Harley Street, London, W.1, to 52 Queen Anne Street, London, W.1 (Tel. Welbeck 5721/2).

Dr. W. M. Cumming, technical director to the British Dyewood Co., Ltd., and formerly professor of technical chemistry in the Royal College of Science and Technology, Glasgow, has retired in order to take up work as a technical consultant.

SCIENTISTS IN GOVERNMENT SERVICE IN BRITAIN

SPECIAL PROMOTIONS

FURTHER special posts have been created in the Civil Service, under provisions included in the White Paper on the Scientific Civil Service (Cmd. 6679; 1945), to provide for the promotion of individual research workers of exceptional merit. They include the following:

Deputy Chief Scientific Officers

DR. R. D'E. ATKINSON. Dr. Atkinson was appointed chief assistant at the Royal Observatory, Greenwich, in 1937, and in 1940 was loaned for degaussing work under the Admiralty. He is now at the Royal Greenwich Observatory, Herstmonceux. Dr. Atkinson is well known for his pioneer work on the mechanism of generation of stellar energy, but has in recent years turned his attention to the problems of positional and meridian astronomy, and has devoted considerable attention to the problem of flexure in transit instruments, this being a recognized source of error in accurate meridian work. He has designed a mirror transit which it is proposed to make for the Royal Greenwich Observatory..

MR. H. B. HOWARD. Mr. Howard joined the Scientific Civil Service in 1916. He has had long and varied experience in aircraft research, and since 1945 he has been assistant director of research on aircraft structures at Ministry of Supply Headquarters, in which capacity he has personally planned and co-ordinated aircraft structural research sponsored by the Ministry of Supply at the universities and in the aircraft industry. He is particularly distinguished as originator of the 'Howard diagram', for his early and far-sighted organization of research on flutter and vibration at the Royal Aircraft Establishment and for many substantial personal contributions to modern aircraft structural research.

DR. G. H. METSON. Dr. Metson joined the Post Office in 1933. Since 1946 he has led a team developing long-life, high-slope, pentode valves for submerged repeaters. His studies of oxide-cathode valves have led to a proper understanding of the causes of failure and to a production line employing novel techniques and rigorous testing and selection. In particular, passive platinum replaces active nickel for the cathode core; the growth of interface impedance and the excessive production and evaporation of metallic barium are thereby avoided and the means for activating and retaining activation on the passive core have been successfully found and explained. Subsidiary studies of other necessary materials and vacua have been made. His valves are in use in the Newfoundland to Nova Scotia section of the Trans-Atlantic Telephone Cable.

Senior Principal Scientific Officers

MR. I. M. DAVIDSON. Mr. Davidson works at the National Gas Turbine Establishment, where he has been primarily concerned with research in the aerodynamics of engines and has made notable contributions to the theory of supersonic flow and supersonic compressors, his recent work on the use of the jet flap to improve aircraft performance being particularly outstanding.

DR. K. H. DOETSCH. Dr. Doetsch is at the Royal Aircraft Establishment. Since 1953 he has been in charge of research and development of auto-pilots, autostabilization gear and powered controls.

DR. L. ESSEN. Since Dr. L. Essen joined the National Physical Laboratory in 1929 he has been concerned with precise microwave measurements, in particular with the measurement of frequency and time. Recently he has developed a frequency standard, based on a resonance of the cæsium atom, which offers the possibility of a more permanent, convenient and accurate fundamental time-standard than the astronomical standards hitherto used.

DR. F. A. ISHERWOOD. Since joining the Low Temperature Research Station, Cambridge, Dr. Isherwood has investigated the chemistry and biochemistry of the cell wall of plants and the soluble constituents of the cytoplasm. Recently, he has been studying the contribution which lignin and other phenolic substances make to the physical properties of the cell wall.

DR. M. S. LONGUET-HIGGINS. Dr. Longuet-Higgins joined the National Institute of Oceanography in 1954. Hitherto noted primarily for his important theoretical studies, he is at present particularly concerned with allied experimental investigations on the generation and changes in the characteristics of ocean waves and with the propagation of storm surges.

DR. L. W. MAPSON. At the Low Temperature Research Station, Cambridge, Dr. Mapson and Dr. Isherwood have made notable contributions to the knowledge of the role of ascorbic acid in plants and animals. Dr. Mapson's studies have been particularly concerned with the biological synthesis of vitamin C in plants and animals, the conditions of its stability and its role as a component of the respiratory enzyme system.

DR. H. SMITH. Dr. Smith has worked at the Microbiological Research Establishment since 1947. He has done outstanding research on the virulence-enhancing action of mucin and on the chemical basis of the virulence of the anthrax bacillus.

MR. J. K. ZBROZEK. Mr. Zbrozek has been working at the Royal Aircraft Establishment on the influence of atmospheric gusts on the flight dynamics of aircraft, using the 'power spectrum' method.

MR. H. ZIEBLAND. Since 1946 Mr. Ziebland has worked at the Explosives Research and Development Establishment, where he has applied engineering skill and theoretical and experimental ability in physics to problems of heat transfer, low-temperature research and thermal conductivity.

Similar promotions have been made by the United Kingdom Atomic Energy Authority as follows:

Deputy Chief Scientific Officer

DR. B. B. KINSEY. Dr. Kinsey became associated with atomic energy in 1942 when he joined the research team working at the Cavendish Laboratory, Cambridge, under the Directorate of Tube Alloys. When part of this project was transferred to Montreal, he joined the group engaged in the determination of the basic data required for nuclear reactors, and then, a year later, moved to the newly founded laboratory at Chalk River, Ontario. There Dr. Kinsey did notable work on the gamma-rays produced by neutron capture. In 1954 he spent a year at the Radiation Laboratory of the University of California as a guest of the United States Atomic Energy Commission, studying the interactions of high-energy protons with nuclei. Since 1955 Dr. Kinsey has held a special research appointment at the Atomic Energy Research Establishment at Harwell.

Senior Principal Scientific Officers

Dr. G. C. Barker. Dr. Barker is in charge of a small electrochemistry section in the group under Dr. E. Glueckauf. He has been responsible for the development of the square-wave polarograph which represents a major advance in polarography. He has studied the electrochemistry of ion-exchange resins and has recently applied the square-wave polarograph to the determination of ions in molten salts.

Mr. W. B. Hall. Mr. W. B. Hall, of the Atomic Energy Authority Industrial Group, is in charge of experimental engineering in the Research and Development Laboratories at Windscale in Cumberland. He has worked on heat transfer and associated problems in reactors with both gaseous and liquid metal coolants.

Mr. J. D. Lawson. Mr. Lawson is distinguished for his work in electron physics. He has studied the behaviour of electron beams in accelerators and the radiation from targets bombarded by high-energy electrons, and has led a team in the development of new types of high-power klystron valves operating in the microwave region. He is at present head of a section of the Accelerator Group at Harwell, in charge of long-term research on particle dynamics in unusual configurations of electric and magnetic fields, with the help of electronic and mechanical analogues.

NEUROCHEMISTRY

INTERNATIONAL SYMPOSIUM IN AARHUS

THE word 'neurochemistry' is coming to mean something rather more than the bare chemistry of nervous tissues. At the second International Neurochemical Symposium recently held at Aarhus, Denmark, the discussion ranged freely from electron microscopy to problems of nervous transmission and drug action. While the metabolism of nervous tissues formed the central theme, the programme reflected a growing appreciation of the significance of biochemistry in relation to the morphology and function of the nervous system.

In the opening session, Prof. F. O. Schmitt, of the Massachusetts Institute of Technology, gave an admirably lucid account of the molecular structure and properties of the nerve cell membrane. He reported that isolated sections of nerve membrane obtained from squid giant axons show a relatively high metabolic activity *in vitro*, suggesting that the membrane may account for a large part of the metabolism of the whole cell. In a discussion of the nature and structure of the myelin sheath of medullated nerve fibres, it appeared that the new evidence obtained with the electron microscope agrees with that derived from X-ray studies in supporting the view that the myelin sheath is made up of concentric layers of a double membrane. According to the 'jelly-roll' hypothesis, the double membrane grows out from the point of contact of nerve axon and Schwann cell, and wraps itself around the axon; but it is difficult to apply this hypothesis to the myelin in the central nervous system. Mr. G. B. David (Cardiff) reviewed the structure of the synaptic terminations, of which some two thousand can be counted on the surface of the large ganglion cells of the brain. He presented evidence that some of the nerve endings terminate in fine filaments which enter the post-synaptic ganglion cells. Recent work on the mechanism of nervous conduction was described by Dr. R. D. Keynes (Cambridge), and the relation of phospholipids to the binding and transport of cations was discussed by Dr. J. Folch-Pi (Waverley). It appears that the phospholipids may be intimately concerned in the operation of the 'sodium pump'.

In a session devoted to the histochemistry and cytochemistry of nervous tissues, Prof. O. H. Lowry (St. Louis) described the spectacular work coming from his laboratory on the quantitative distribution of enzymes in individual ganglion cells, obtained by micromanipulation from different parts of the brain. Some enzymes are evenly distributed throughout the cytoplasm and others are located especially at the cell surface. Asked by Dr. M. G. Larrabee (Baltimore) if he had yet made measurements on individual mitochondria, Prof. Lowry replied: "No. But there is another Symposium in two years!". Cytological aspects of nucleic acid metabolism were reviewed by Prof. L. Einarson (Aarhus), who discussed in particular the changes associated with functional activity of the neurone. Dr. J. E. Edström (Gothenburg) reported a very outstanding piece of work on the purine – pyrimidine analysis of the ribonucleic acid in individual nerve cells of the hypoglossal nucleus, using a combination of chromatography on single cellulose fibres and ultra-violet microspectrophotometry.

Other sessions dealt with the general metabolism of the brain *in vivo* and of isolated ganglia, brain slices and peripheral nerve. The role of coenzymes in group activation was reviewed by Prof. F. Lipmann (Boston), and Prof. H. McIlwain (London) contributed a paper on the speed of chemical changes in the brain. Prof. H. Waelsch (New York) reviewed the nitrogen metabolism of the brain and described new results with radioactive lysine which confirm the earlier work with radioactive methionine in showing the high metabolic activity of the proteins. The rate of incorporation of labelled amino-acids is greatest in the microsomes, and Dr. D. Clouet (Cardiff) reported the isolation from the microsomes of a highly active nucleoprotein which accounts for a large part of the amino-acid turnover in the proteins of the brain. Lipid metabolism was discussed by Prof. R. J. Rossiter (Ontario) and Prof. E. Klenk (Cologne). Prof. F. Lynen (Munich) contributed a review of the role of acetyl–coenzyme A in the synthesis of fatty acids.

In the closing session, devoted mainly to the biochemistry and physiology of pharmacologically active compounds and drugs, Dr. W. Feldberg (London) gave an account of the role of acetylcholine in the central nervous system. Dr. M. Vogt (Edinburgh) described recent work on the distribution of adrenaline and noradrenaline in the brain, and concluded that the tranquillizing drug reserpine appears to act by restricting the retention of basic metabolites in the tissue. Serotonin metabolism was reviewed by Dr. S. Udenfriend (Bethesda) and histamine by Dr. G. B. West (London).

The proceedings of the Symposium will be appearing shortly under the title "Metabolism of Nervous Tissue", edited by Dr. D. Richter and published by the Pergamon Press, London.

SOCIETY OF LEATHER TRADES' CHEMISTS

ANNUAL CONFERENCE

THE annual conference of the Society of Leather Trades' Chemists was held in the University of Leeds during September 21–22, the chair being occupied by the president, Dr. R. G. Mitton. The morning session of the first day was opened with a paper by Dr. G. H. Green on the mechanism of liming and bating. The main object of bating is to prevent adherence of leather fibres on drying, and evidence was put forward which leads to the following scheme:

$$\text{intact collagen} \xrightarrow{\text{lime}} \text{progelatin} \xrightarrow{\text{heat}} \text{gelatin} \xrightarrow{\text{trypsin}} \text{peptides of low molecular weight}$$

Progelatin consists of filamented collagen fibres produced on the newly formed collagen fibre-surface after liming or other swelling treatment, which, by its polar nature, acts as a glue when the fibres are dried. Removal of this progelatin restores the isoelectric point of the collagen, previously lowered to about pH 5·0 by alkali hydrolysis, and progelatin causes what is technically termed 'falling' and develops air-permeability and some silkiness of the grain surface of the pelt. Re-liming a skin after bating causes a serious loss of substance by progelatin formation, due to the bating enzymes assisting the action of the lime.

The tanning characteristics of aliphatic aldehyde–ketone resins were then discussed by J. R. B. Hastings and Dr. T. White. A resin tannage was described in which the hide is first impregnated with a condensate prepared by the alkali-catalysed reaction between an aliphatic aldehyde and ketone, which is afterwards resinified *in situ* by further alkali treatment. The leather can contain up to 20 per cent of resin with an increase in shrinkage temperature of 14 deg. C. The condensates can be converted into water-soluble products by treatment with sulphites or bisulphites and employed by conventional tanning methods. The role of the sulphonate group in the solubilized products was discussed and further compared with analogous sulphonated tanning materials. The aldehyde–ketone condensates were thought to have potential value if used with other tanning materials.

The last contribution to the morning session was a paper by Prof. D. Burton and Dr. R. Reed on some further electron-microscope researches, in which the structural changes in tanned collagen fibrils during shrinkage in hot water were described. First, the fibrils swelled either at certain regions along their length or at their ends. The bands across the fibrils became fainter in the swollen regions and, significantly, became much closer together. At the same time the swollen portions flattened and assumed a peculiar spiral form. This initial swelling was usually observed at a temperature below that of macro-shrinkage—that is, below that of a strip of leather as determined in the usual apparatus. Moreover, the fibrils in any particular sample of leather did not all swell and shrink at the same rate. On raising the temperature, the swollen fibrils broke across to form short stubby structures, which on prolonged heating were reduced to ill-defined masses of glue-like material. These changes appeared to take place with all the leathers so far examined, but were best illustrated in the case of chrome and oil-tanned leathers where the fibrils were not obscured by the presence of amorphous material such as vegetable tannin. On the basis of these results, suggestions were put forward for the structure of the native collagen fibril, its stabilization by tannage and its shrinkage by hot water.

The afternoon session was devoted to the delivery of the seventh Procter Memorial Lecture by Dr. G. W. Kenner, who selected for his subject the present and future scope of peptide synthesis. During recent years, great advances have been made in the analytical and structural chemistry of proteins and the question must be asked whether synthesis will keep pace. No deep and rapid incursion into this field should be expected, but progress in two directions is discernible. Oligopeptides containing some ten amino-acid residues arranged in a definite sequence can now be constructed from most, if not all, of the amino-acids which occur in proteins; the chief interest in such compounds has lain in their relation to hormones and antibiotics, but they may also prove useful as models in studies of protein reactions. Many polypeptides have been synthesized from single amino-acids, and the possibility of repeating many times a given short sequence is now apparent.

For building oligopeptides of defined structure, one still relies fundamentally on the approach made by M. Bergmann—namely, protection of the terminal amino-group of an amino-acid or peptide, while the terminal carboxyl group is condensed with the amino-group of another section of the peptide chain. However, the actual range of methods is now much greater than that which was available to Bergmann. In addition to Bergmann's carbobenzoxy-protecting group, one now has the tosyl, phthaloyl and trityl groups—to name only the most important—and in addition to the azide method of condensation, there are those methods relying on various mixed anhydrides, cyanomethyl esters, thiolesters, derivatives of trivalent phosphorus, and carbodi-imides. The power of these methods has been amply demonstrated in the syntheses of oxytocin and related compounds by du Vigneaud and his colleagues as well as by other groups of workers.

Polypeptides have been synthesized from the N-carboxyanhydrides of amino-acids; but this method is not applicable to the production of material containing more than one amino-acid and having a defined structure. For this purpose some of the methods used in the synthesis of oligopeptides can be adapted; but there are many problems in securing reasonable yields of material with a high molecular weight. Nevertheless, progress along these lines can be confidently expected.

The remainder of the afternoon of the first day was occupied by the annual general meeting of the Society.

The morning of the second day of the conference was opened with a paper by N. L. Holmes and H. G. Wollenberg on investigations into the rate of tannage of sole leather. In this work, which was devoted to a study of the effect of temperature on the rate of tanning of sole leather, it was found generally that the total uptake of tannin increased with increase in temperature, as also did the rate of uptake, the temperature-levels used being 8°, 18°, 28° and 38° C. This was followed by the concluding paper of the meeting, by J. M. Harrison and T. Turner, on some experiments on the impregnation of sole leathers, in which were described some laboratory-scale experiments on the use of polymeric materials to improve abrasion resistance and water repellence of sole leather. The factors associated with emulsion impregnation and solvent impregnations were discussed. Many of the monomers, which on polymerization would give the type of elastomer required, are very volatile, and this has presented one of the difficulties. One method of *in situ* polymerization has been developed which gives a leather of improved properties.

LIBRARY PROBLEMS IN GREAT BRITAIN

IT is difficult to discern a common thread in the papers presented at this year's conference of the Library Association, held in Folkestone during September 18–21, though several of them stressed the importance of an adequate library system in relation to technological education and indeed to further education and the dissemination of information generally. In his paper on libraries in colleges of technology and further education, Mr. L. L. Ardern attacked the Government's failure to implement plans for an adequate national library service, at any rate for science and technology, and he was fully supported by Dr. G. Chandler and, at least by implication, by Mr. O. S. Tomlinson, who, reviewing post-war influences on librarianship, referred to the indifference of the teaching world, except in the universities and grammar schools, to the educational value of books.

Mr. Ardern began with a most interesting review of the early development of technical college libraries down to the official admission of their vital importance, which he welcomed, in the recent White Paper on Technical Education; but he showed convincingly how poor is the overall provision and how great is the need for some effective regional co-operation in each industrial area between the public libraries, the technical colleges and industrial libraries. Mr. Ardern remarked that we do not ask often enough how much duplication we can afford and suggested that this is a field where local co-operation would be particularly valuable, though the technical college library has to give priority to the subject fields of the departments it serves, and this limits the extent to which it can serve other fields.

Mr. Ardern fully recognized that the library is only a part of the technical college and that we cannot expect the part to be healthy, virile and progressive if the whole is not. He was clearly sceptical as to the Government's proposals for technical education providing us with colleges which are not overcrowded, under-staffed and under-equipped. Dr. G. Chandler, discussing present trends and future developments in large municipal libraries, did not mention the technical colleges, but in his reference to special libraries, to technical libraries and to patent libraries he was likewise concerned with the Government's failure to implement the recommendations of the Advisory Council on Scientific Policy. The rapid dissemination of scientific and technical information is probably, he said, from the national point of view the most vital library problem, and large public libraries will not be able to meet the varied specialist demands of to-day unless the Government gives them much greater preferential treatment than at the moment. The Government does not realize, he said, that large public libraries are, in effect, national institutions and that they serve an even more advanced section of society than either the technical colleges or universities.

Dr. Chandler urged that libraries have as large a part to play in education as have schools and colleges, and that education is more than ever a pre-requisite of our survival in a fiercely competitive world. In this he and Mr. Ardern were fully supported by Mr. E. R. Lake in a paper on reading in the television age, as well as by the president of the Association, Mr. Edward Sydney, who concluded his presidential address by remarking that the public library service in any really democratic society is, and always will be, an essential instrument in enabling its citizens to live wisely, agreeably and well. Mr. Sydney devoted his address mainly to developments during the decade since the Second World War, stressing, like Mr. Ardern, in his more limited field, the need for greater co-operation, for high standards in provision of books, of service and of staff; Mr. Sydney also gave a brief glance at the international field, which was surveyed in greater detail by Dr. H. Coblans in a paper entitled "International Librarianship—Some Problems and Implications". To the scientist the chief interest of Dr. Coblans's paper lies in his reference to the opportunities which bibliography, documentary reproduction and translation offer for international action. Commenting that, in spite of some improvement in co-operation between national services in certain subjects, the abstracting services as a whole deteriorate every year, becoming more expensive, less complete in coverage and more numerous, Dr. Coblans said that international agreement to co-operate along well-defined lines offers the only hope of solution. *Chemical Abstracts*, he remarked, in 1956 costs six times what it cost in 1955. During the past few months Unesco has accepted some responsibility for defining the problems presented by the automatic printing of large numbers of references or index entries and the solution of items of knowledge on a given subject, and also for stimulating research and study for centres at various stages of library development.

Mr. D. J. Foskett, in a paper entitled "Science, Humanism and Libraries", maintained that science is much more than the accumulation of masses of data and that the failure to realize this is a major cause of misunderstanding and of breakdown in the communication of science. In the course of his work the scientist gains new knowledge and new ideas which are capable of inspiring him with emotions akin to those felt by the poet and the artist, and these have to be communicated in such a way that others also can appreciate their significance. Mr. Foskett thought that it is important to get into our libraries those works which deal with the specifically human side of science, such as the histories and biographies, and that one reason why scientists become so specialized in outlook is the mere mass of publication, some of a very low standard and much of it repetitious. He suggested that libraries should attempt to discourage unnecessary publication and also that those possessing special knowledge should use their opportunities to produce works of wide interest, such as guides to the literature and bibliographies.

Mr. K. C. D. Vernon's admirable factual account of the libraries and work of some learned societies began, like Mr. Ardern's paper, with a historical review. Broadly speaking, he suggested, the strength of many of these libraries lies in their collection of periodicals, and he regretted that the holdings of many of these libraries are not recorded in publications such as the "World List of Scientific Periodicals". Some of these libraries have almost unknown riches on their bookshelves, and many have important collections of manuscripts. Many of them, however, are undeveloped and largely unknown except to small groups of people. Their resources could add much more to scholarship ; but although some, particularly those serving expanding professions, have been forging ahead, recataloguing and rearranging their books, binding old books and introducing more up-to-date methods, much remains to be done before these libraries are fully mobilized to serve their societies.

THE MELLON INSTITUTE

REPORT FOR 1955-56

THE annual report of the president, Dr. E. R. Weidlein, to the Board of Trustees of the Mellon Institute, Pittsburgh, for the year ended February 29, 1956*, records that expenditure on pure and applied research was 5,009,213 dollars, of which 1,125,213 dollars was in support of original investigations in pure science in the Institute's five research departments and conducted under the auspices of thirteen fellowships. The report traces the idea of setting up a partnership between American industry and science, which the Institute represents, to Dr. R. K. Duncan who, after attending the Sixth International Congress of Applied Chemistry, held in Rome in 1906, arranged for the first industrial fellowship at the University of Kansas on January 1, 1907. During the past year 160 members of the Institute were engaged in pure science research projects and 412 members on the applied science researches conducted under fifty-eight fellowships. Of these seventy-one fellowships, 44 were multiple and 27 individual; four had been proceeding for forty years, four more for thirty-five years and six for twenty-five years.

Investigations in the Department of Research in Chemical Physics have included a detailed study of sodium, potassium and calcium salts to determine the magnitude of the anion effects in flame photometry, the redetermination of the infra-red spectrum of heavy benzene in both gas and liquid phases, and studies of the effect of temperature on the infra-red spectra of cyclohexane and dioxan ; special equipment was assembled for measuring the intensity of X-ray scattering at very small angles. In the Department of Research in Physical Chemistry the study was completed of the effects of packing density and annular width on the separating efficiency of packed thermal diffusion columns, and work was considerably extended in chromatography. Three high-efficiency distilling units capable of handling charges up to 20 l. have been designed and installed, and a start made on the design of an automatic take-off system. Work on the determination and correlation of physico-chemical properties of hydrocarbons of high molecular weight continued, and the changes in pore-volume distribution of reactivated filtration clays are being followed in co-operation with the Multiple Petroleum Fellowship, and the absorption and desorption phenomena of porous glass in co-operation with the Glass Science Multiple Fellowship.

There is a continuing demand for workers in the Department of Instrumentation to construct instruments previously developed in it or by others, and also for training in the operation of instruments. In a basic study of the recording micro-balance and weighing techniques a procedure has been developed to adjust the instrument to be very insensitive to the tilt of the building and balance table. In the Department of Applied Mathematics a study has been made of the mathematical models used in predicting the concentration of atmospheric pollution ; work has also been begun in the Department on programming and coding a routine for calculating structure factors used in crystal-structure analysis by the Department of Research in Chemical Physics, and assistance has been given the Multiple Glass Science Fellowship in determining light scattering in glass as a function of fluctuations in anisotropy and density and to the Multiple Petroleum Fellowship on statistical analysis and experimental design in the engine testing of petrol and oils.

Following preliminary studies, in co-operation with the Multiple Fellowship on Petroleum, with a Lingane-type of potentiostat, the Department of Analytical Chemistry has provided a more widely adaptable instrument for coulometric analyses at controlled potentials and has expanded its microbiological and microscopical services during the year. A new microtome permits the preparation of cross-sections of biological and inanimate materials as thin as 0·05 μ, and a new stereoscopic microscope is an invaluable aid in selecting areas for photomicrography and for the examination of surfaces. A study of the effect of micro-organisms on petroleum and petroleum products was commenced, and procedures were formulated for cultivating and counting micro-organisms in aerosol dispersions. The expansion characteristics of starches and flours were studied in co-operation with the Food Varieties Multiple Fellowship, and the fundamental study of the chemo-synthetic autotrophic bacterium, which has been designated *Ferrobacillus ferroxidans*, isolated from bituminous coal-mines was continued.

Reviewing the work carried out under the Fellowships in Pure Science, the report stresses the work of the Industrial Hygiene Foundation, which has now completed twenty years of service to industry, including 380 companies in its membership, for which seven hundred special studies have been made as well as fifty basic research programmes in the Foundation's laboratories. Field investigations during the year included the determination of the magnitude of the in-plant contamination of the air with hexavalent chromium compounds, and the magnitude of fluoride exposures in specific areas of a chemical plant. A study was being made of the incidence of occupational dermatitis due to specific substances and the importance of these substances as causative agents in industrial dermatitis, and another of the effects of abrasive dust on normal lungs and on the evolution of pulmonary tuberculosis. Work under the Multiple Fellowship in Chemical Hygiene is being devoted mainly to the study of the safety of chemical residues remaining in food as a result of new developments in its production, processing and packaging, and the low level has been demonstrated of sensitizing ability of a new epoxy resin catalyst now being introduced. Under a fellowship in the effect of atmospheric moisture on air-borne bacteria a better understanding has been yielded of the water exchange between bacteria and their atmospheric environment and of the way in which certain chemicals alter this relation when bacteria are dispersed from suspensions of these substances. The Fellowship in Mine-Acid Control is now applying the accumulated information of nine years to a large complete watershed in a coal-mining area. The Multiple Fellowship in Glass Science has developed improved procedures for measuring the nuclear-spin relaxation-times of the silicon-29 atoms in glass, continued its study of irradiated glasses and commenced experimental studies on the surface of glass. The Multiple Fellowship in the Properties of Synthetic Rubber, now sponsored by the United States National Science Foundation, has scrutinized the determination of macromolecular sizes by methods of intrinsic viscosity and molecular weight and also the application of this technique to studies of branching in polymers. The degree of orientation caused by stretching the elastomer has also been investigated, and the response of solid rubber compounds to sinusoidal stresses. A filler has been developed that possesses a static buoyancy similar to that of buoyant glass fibres, in which the inherent strength, bulkiness and resiliency of a synthetic staple fibre of extremely small diameter are combined with the water repellency of a silicone polymer, and further tests are being made of the efficiency of this product. By combining xerography with electroluminescent powders, workers under the Multiple Fellowship on Carpenter Components have produced panels containing self-luminous information displays, which appear to be specially attractive for instrument panels.

---

* Scientific Research Progress in Mellon Institute, 1955–1956. (Annual Report Series, No. 43.) Pp. vi+54. (Pittsburgh, Pa.: Mellon Institute, 1956.)

About 60 per cent of the report is concerned with the research programmes of the Fellowships in Applied Science, and among the points of more general interest which may be mentioned are the fundamental studies on the ageing of selenium rectifier plates made under the Multiple Fellowship in Power Rectifiers and the construction of a furnace to grow single crystals of silicon in a vacuum or in an inert atmosphere with independent pulling and rotation of the seed crystal. A study of the interaction of organic ammonium salts with bentonite has led to a stabler clay complex which is organophilic and hydrophobic and is used in gelling oils to greases and in controlling the thixotropy of oil-base paints. Considerable success has been achieved in determining the optimum water content for the proper extrusion of clay–water mixes by use of the 'Brabender plastograph', and an apparatus has been designed and constructed to measure the force-deformation characteristics of green clay bars under transverse sheer. Progress has been made in the development of cover-coat enamels with improved alkali resistance for use on sheet steel. Several interesting organic derivatives of zirconium have been prepared, and the production of a metal zirconium plate by electrolysis in non-aqueous media investigated. A comprehensive information-processing system, utilizing commercially available computers, communication systems and other devices, has been designed, and much basic research has been done on fundamental problems in the painting of steel structures, such as anchor-pattern profile, blast-cleaning inhibitors, and cleaning agents. An investigation of natural sediment in streams was commenced, and progress has been made with paper chromatography as a method for differentiating phenolic compounds and in a study of odour thresholds of pure phenolic compounds. Low-temperature crystallization techniques have been developed for the purification of organic compounds, and alloys of unusual characteristics have been developed by the electromelting of waste products from the recovery and utilization of anthracite.

Improved methods of synthesis have been devised for certain of the porphyrins and their metallic complexes, and the structure of the vanadium complexes determined. Volatility studies have been made on some of these metallic complexes, and studies initiated on the thermal stability of various sulphur concentrates from crude petroleums. A chemical shock tube has been designed and constructed for a fundamental study of combustion reactions, and a new micro-catalytic chromatographic technique developed for studying catalytic reactions, which promises to accelerate the accumulation of data on new catalysts. An extensive study was made of the chemisorption of nitrogen, carbon dioxide and carbon monoxide on nickel catalysts, prepared in the presence of alkali, and studies were continued on the composition and properties of fractions of high molecular weight from petroleum, while the use of calcium phosphates as a solid catalyst or catalyst carrier for various industrial reactions received detailed attention. Phase-contrast photomicrographs have been taken of a wide variety of plain and modified starches before and after heat treatment, and several modifications have been made in the method of synthesizing the bacterial starter from which salt-rising bread is manufactured.

A new dextrin has been developed for use as a high-performance size for filament acetate, and methyl glucoside has been used in the preparation of long oil-modified alkyl resins, oil derivatives and modified amino-formaldehyde resins. Compounds have been discovered with excellent detergency at low concentration in perchloroethylene, and the synthesis and evaluation of soluble linear polymers were continued; a comprehensive study of the autoxidation of polyalkylene oxide derivatives has revealed that carbon-to-carbon bonds along the whole length of the polyalkylene oxide chains, as well as terminal hydroxy-alkyl groups, are vulnerable to oxidative attack Considerable effort has been given to the synthesis of materials for use as, or in, high-temperature lubricating and hydraulic fluids, and more than fifty systems were examined for the stabilization of vinyl films to heat and light. The field of polyethylene/paraffin wax blends for coating paper-container stock was explored further, and methods were sought for determining the wettability of a metallic surface by a coating and the ability of a coating to flow on a metal surface. New techniques were developed for the preparation of functionally active siloxanes, and a special glow-proofed 'Neoprene' foam, which meets flame and smouldering-resistance requirements, was being developed. Besides the preparation of 6-diazo-5-oxo-L-norleucine, which is highly effective in inhibiting the growth of malignant tumours in mice and rats, studies of the mechanism by which the antibiotic, azaserine, inhibits the growth of malignant tumours showed that azaserine blocks at least one previously unknown enzyme from carrying out a key reaction involving L-glutamine and led to the identification of formylglycinamide ribotide as the reactant and formylglycinamidine ribotide as the product of the blocked reaction.

SPACE PERCEPTION IN CHICKS

ECKHARD H. HESS has carried out investigations to ascertain whether a chick's visual perception of space depends upon learning or upon the maturation of an innate ability (*Sci. Amer.*, July 1956).

Experiments were devised to prevent normal visual experience and which would not interfere with the normal physiological development of the eye. This was done by fitting the chicks' eyes with prismatic lenses which would displace the visual image to the right or to the left.

If the exact visual localization of objects in space is a totally learned ability, the chick's performance would be unaffected by the fact that it is wearing displacement prisms.

If, on the other hand, the chick is born with an innate ability to locate objects visually, the first pecks which such a chick directs toward objects seen through the displacement lenses would be about seven degrees to the right.

In experiments, twenty-eight Leghorn chicks were hatched in complete darkness and were immediately fitted with thin rubber hoods into which transparent plastic goggles had been inserted. The hoods were placed over their heads quickly in such a subdued light that the animals had essentially no normal light experience.

All the animals were returned to darkness for a period of about six hours so that they could become accustomed to the hoods. Then, when they were about one day old, all were tested for pecking accuracy. They were allowed to strike at small objects embedded in modelling clay. The targets were small brass nails, embedded so that they could not be dislodged by pecking.

There was a fundamental difference in the performance of control and experimental animals. In the control group the pecks were scattered about the target so that the target itself formed the centre of the distribution. For those chicks wearing lenses which displaced the visual field to the right, the pecks were similarly scattered; but they were centred about a point seven degrees to the right of the target. Similarly, the group the lenses of which displaced their visual images to the left showed a scattering of pecks to the left of the target.

Actual grain was now scattered and, when the chicks were between three and four days old, they were tested again. The results showed a great increase in accuracy on the part of the control chicks: now their pecks clustered quite closely about the target.

Among the animals wearing displacement prisms, improvement of a kind had also occurred. The pecks were clustered just as tightly as those of the controls, showing that increased accuracy had certainly been achieved.

It would appear that the chick's visual apparatus for locating objects in space is innate and not learned. This conclusion is based on the fact that the chick wearing displacement prisms clustered its pecks about the spot where the object was seen. It did not peck at random until it struck the target.

Moreover, the chick the visual field of which was displaced appeared unable to learn through experience to correct its aim. Its only improvement was to increase the consistency of the distance by which it missed the target. Apparently, the innate picture which the chick has of the location of objects in its visual world cannot be modified through learning if what is required is that the chick learns to perform a response which is antagonistic to its instinctive one.

Further experiments showed that adult chickens and newly hatched chicks used binocular cues for localizing objects in space. This innate organization for the perception of depth requires neither learning nor continued use for its presence in the adult animal.

HOME CARE AND NURSING

AN entire issue of *The Practitioner* is devoted to home care and nursing (179, No. 1057; July 1956). In an introductory article Dr. G. E. Godber notes two features of the National Health Service in Britain which have tended to be overlooked. One is that the Service depends primarily upon comprehensive home care, with hospitals and specialist services only for diagnosis and treatment of illness outside the scope of the family doctor and his supporting team. The other is that "the greatest innovations of the Service have been the domiciliary consultation with a consultant and the general provision of home helps". In other words, as Dr. Metcalfe Brown points out in his article on the domiciliary services available to the doctor, "The preventive services and the hospital service are there to help the family doctor, not to displace or replace him".

From the inception of the National Health Service the hospital service has absorbed a large proportion of the not inconsiderable sum which the nation spends upon the Service. Thus, during 1953–54, according to the Guillebaud Report, the hospitals absorbed more than 61 per cent of the £430 million spent on the Service that year, compared with only a little more than 12 per cent spent on the general medical service. Even if the cost of the pharmaceutical service is included in that of the general medical service, the proportion is still only a little more than 21 per cent.

There can be little doubt that if more attention were devoted to the development of the domiciliary services available to the general practitioner, the unnecessary load now carried by the hospitals would be radically reduced. Further, and equally important, the standard of general practice would be improved, to the greater benefit of the individual patient. The symposium provides an authoritative review of the services available to the general practitioner and of examples of how these services can be developed. The emphasis is upon the home care of children as these form such a vitally important part of the work of the family doctor; but all aspects of home care are integrated into the general picture. Three of the articles are written by medical officers of health. This is a sign of the increasing realization of the need for the closest possible co-operation between the medical officer of health, who is responsible for most of the domiciliary services, and the general practitioner, for whom these services are intended.

CASTE AND THE JAJMANI SYSTEM IN INDIA

IN works about caste it is rare to find an analysis of how the different groups interact with one another in the production and exchange of goods and services. William H. Wiser, in his book "The Hindu Jajmani System", described how goods and services are exchanged in a rural Indian village and analysed jajmani relations as a system. Knowledge of this jajmani system is essential for an understanding of the economic aspects of caste in rural India; its methods of working have been investigated and described by Prof. Oscar Lewis and Dr. V. Barnouw (*Sci. Mon.*, 83, No. 2; August 1956).

Under the system each caste group within a village is expected to give certain standardized services to the families of other castes. A khati (carpenter), for example, repairs tools, while a nai (barber) cuts hair; but they do not necessarily perform these services for everyone. Each man works for a particular family or group of families with which he has hereditary ties. His father worked for the same families before him, and his son will continue to work for them, the occupation or service being determined by caste. The family or family-head served by an individual is known as his jajman, while the man who performs service is known as the jajman's kamin or kam karne-wala (literally, worker). These are the terms used in north-western India; where the system prevails in other parts of India other terms may be used.

It is a characteristic of the jajmani system to operate without much exchange of money. For it is not an open-market economy, and the ties between jajman and kamin are not like those of employer and employee in a capitalistic system. The jajman compensates his kamins for their work through periodic payments in cash or grain, made throughout the year on a daily, monthly or bi-yearly basis. Kamins may also receive benefits such as free food, clothing, and residence site, and the use of certain tools and raw materials. These concessions represent the strength of the system and are more important than the monetary payments. Despite the increased use of money in recent years, the peasants tend to prefer grain payments to cash, since grain prices have risen so enormously in the past decade.

There is evidence that the jajmani system exists in eastern Uttar Pradesh, parts of Malabar and Cochin, the Mysore District, Tanjore, Hyderabad, Gujarat and the Punjab.

A major function of the jajmani system is to assure a stable labour supply for the dominant agricultural caste in a particular region by limiting the mobility of the lower castes, especially those who assist in agricultural work. If a kamin leaves the village, he must get someone to take his place, usually a member of the same joint family. This does not usually involve sale, and the jajman is not likely to object, as long as the position is filled. Such transfers are rare, the kamins having valued rights and advantages which make them hesitate to move. Moreover, the community may put pressure on an individual to make him stay.

Jajmani rights, however, which link an individual to certain families, may be regarded as a form of property passing from father to son. Like land property, it is equally apportioned among brothers when they separate.

The widely held view that the caste system is crumbling rapidly in India is not borne out by examination. Although the jajmani system is tending to decline, this will not necessarily be followed by an automatic or speedy disintegration of the caste system. Instead, caste may continue to take on new functions and manifestations.

CAPILLARY FILTERS OF KNOWN AND ADJUSTABLE PORE-SIZE

By LEV AKOBJANOFF

Institute of Engineering Research, University of California, Berkeley 4, California

RODS of even thickness, when closely packed in parallel arrangement, produce a bundle of straight capillaries, with lumen corresponding approximately to one-sixth of the rod diameter. A possible use of such capillaries is in filtration, for example, by connecting an element of the kind shown in Fig. 1 to a syphon or some other suction system. Capillary filters of such structure are characterized by pores, which are (1) uniform, (2) of known size, (3) adjustable by more or less tightening the outer press. These three features have not been realized hitherto in any type of filter, in spite of considerable efforts in many instances[1]. Besides filtration, they open possibilities in other fractionations by size, for example, in sieving, diffusion, etc.

Among the materials which can be used in manufacturing capillary systems of the above kind, artificial textile fibres are of importance. Table 1 gives some characteristics of a few synthetic fibrillæ.

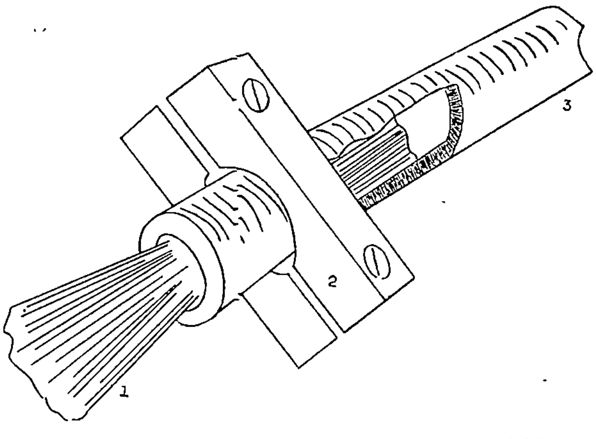

Fig. 1. (1) Rods and capillaries; (2) press; (3) plastic tubing

Table 1

Fibrilla	Composition	Cross-section (ref. 2)	Thickness (microns) (ref. 3)	Per cent swelling in water (ref. 3)
Acetate rayon	Cell. acetate	Crenulated	11 ± 30%	6–30
Casein	Protein	Circular	20 ± 13%	Very large
'Dacron'	Polyester	Circular	11 ± ?	0
Glass	Silicate	Circular	2·5 ± 20%	0
'Nylon'	Polyamide	Circular	11 ± 6%	2
'Orlon'	Acrylonitrile	'Dog-bone' shaped	18 ± ?	Very slight
Rayon	Cellulose	Crenulated	10 ± ?	'Viscose: 45–82 'Cu-NH$_3$': 99–134

The logical way of obtaining regularly packed rods from fibres is, of course, by reeling continuous filaments, for example, from commercially available bobbins. A procedure of this kind has been used by Hopkins and Kopany, who, however, were not interested in capillaries, but manufactured bundles of transparent fibres for the conveying of optical images[6]. For our purposes, the reeling is done on wheels the circumference of which is 2^n times the desired rod-length (n is any whole number), taking no particular care to deposit the fibres strictly parallel, because capillary forces arrange this automatically later, when the filter is wet.

Having deposited a counted number of turns, the pad obtained is cut open, taken off the wheel, and plied n times. Using a 'fish-wire', the 'tuft' is pulled into the tubing. If desired during this operation, the bundle can be given a precise length by neat cuts at both ends. A sharp knife is sufficient for cutting organic material. Glass can be sheared by scissors or cutting pliers (sawing by a 'Carborundum' disk—even water-lubricated—seems to produce sintering and plugging). As regards fibre length, I have observed that the rate of fluid transfer through the filters depends primarily on the zone of compression, being, for example, the same for filters cut flush with the faces of the clamp and others which extended in loose 'brushes' of irregular fibre length as far as 5 cm. beyond one or both sides of the restriction.

However, in filtration proper, these two types of capillary filters, the loose-end 'brush' and the clean-cut 'slice', may cause specific fractionation effects. The brush-filter and the slice (if at the end of the tube) are easily manufactured by the method described above. A filter-slice with free ends of tubing on both sides can be made by first cutting out a disk from a bundle of fibres packed within plastic tubing and then by pushing it into a larger tube, or by press-moulding or cementing it between two ends of tubing.

For a tube of 6·25 mm. inner diameter the following numbers of filaments can be used: 'Dacron' (DuPont 70-34-0-5,600-semi-dull), 20,000; glass (Owens–Corning *ECD*-900-1/0-'Fiberglass'), 8,000; 'Nylon' (DuPont 7-1-0-0-200-semi-dull), 40,000; 'Orlon' (DuPont 75-30-0-7281-semi-dull), 16,000; 'Rayon' (American Bemberg 50-36-44-*HH*-cupro ammonium), 4,000. These numbers of filaments and the press, the bore of which was ⅜ in. (= outer diameter of the tube) with ⅛ in. clearance for compression, allow of regulating aqueous flow (in ml. per hr.), through a syphon of 10-in. head, between 6·5 and 0·3 for 'Dacron'; 3 and 0·2 for glass; 7 and 0·05 for 'Nylon'; 4 and 0·5 for 'Orlon'; 3 and 0 for 'Rayon'.

Unfortunately, many fibrillæ (among them almost all natural and the thinnest artificial) are not available in continuous fibres. In this case, roughly parallel packing can be obtained by cutting staple fibres somewhat longer than twice the desired tuft length and then combing out the shorter fibrillæ. Weighing allows the estimation of the number of fibres per cross-section. For a tube of 6·25 mm. inner diameter, the weight in gm. per cm. length may be: for 'Rayons' and wool, 0·26; 'Nylon' and cotton, 0·35; for glass, 0·8. Otherwise, the procedure of manufacturing follows the pattern outlined above, the final packing and orientation by capillary forces being even more important here.

For various fluids specific interactions with the rod-materials can be expected. Water, for example, swells many fibres, as shown in Table 1. I have measured the decrease of water transfer (in ml. per 24 hr.) during consecutive days through capillary filters of cupro-ammonium 'Rayon' as follows: 11, 10, 9·5, 9, 8, 9, 8, 7·5, 5, 5, 5, 4, 4, 4, 3, 3, 3. Since the available space is limited by the outer press, expansion of the swelling fibres occurs into the capillary ducts, decreasing the lumen of pores. This can be used in constructing a capillary filter, with an outer metallic ring in place of a clamp, variable compressions and pore sizes being obtained by varying the number of fibres. For example, in the lumen of a 6·25-mm. tubing with an outer diameter of 9·375 mm., tightly fitted into a brass ferrule of 1 cm. in length, the following numbers of filaments (American Bemberg 50-36-44-*HH*-cupro ammonium) 3,800, 3,700, 3,600, 3,500, 3,400, 3,300, 3,200, 3,100, 3,000 gave, after two weeks of stabilization, flows of 0·0089, 0·024, 0·0328, 0·037, 0·0685, 0·089, 0·104, 0·1425, 0·226 ml. per hr., respectively, the head being 75 cm.

When using a water-resistant material like glass, several molecular layers of water are adsorbed by the surface of the rods[4], also producing clogging. Correspondingly, the flow of water through a capillary filter of glass decreases as follows under the same conditions as above: 11, 10, 9, 8, 7, 8, 7·5, 7. Obviously, the 'known' size of the capillaries cannot be calculated simply from the rod thickness in the 'dry' condition. It will vary and will have to be determined for each filtering medium. Presumably hydrodynamic methods will give strict answers, since the number of capillaries is known and their shape is very close to the ideal straight canals required by theory[5]. In an orientation test of this possibility, a glass filter composed of 816,000 fibrillæ, 6·275 microns thick, in tubing of 6·25 mm. inner diameter and an effective capillary length (zone of compression) of 10 mm., conveyed 22 ml. of water per 24·5 hr., the head being 121·5 cm. These flow data correspond to a capillary 'diameter' of 1·468 microns, whereas a geometrical computation yields 1·426 microns. (Assuming the arrangement of fibres as hexagonal–concentric, the ratio of holes to rods for the N'th row is $(2N-1):N$; the total number of capillaries tends to twice the number of rods with increasing counts of the latter.) On the other hand, the pore 'diameter' for the above cupro-ammonium filters with decreasing numbers of fibres has been calculated to be: 0·408, 0·530, 0·575, 0·600, 0·700, 0·750, 0·790, 0·869, 0·975 micron. These figures indicate 'diameters of pores'. However, under the microscope, cuts through closely packed swollen 'Rayon' fibres look more like regular hexagons of a tile-pavement, displaying no circular lumen. The pores are the rectangular gaps between hexagons, and the calculation of their width should probably be done by dividing the area corresponding to the above diameters, that is, 0·131, 0·221, 0·26, 0·283, 0·386, 0·44, 0·49, 0·58, 0·755 square microns by the length of a hexagon edge (approximately 8·5 microns). By this procedure the pore widths come out as: 0·015, 0·026, 0·030, 0·034, 0·045, 0·053, 0·060, 0·068, 0·090 microns. This should be closer to reality; but the ultimate determination of the size of the pores will be by filtration (diffusion, etc.) of particles of known diameters.

I may add that capillary coils as produced by wrapping sheets, and capillary boundaries between sheets in stacks (flat or curved) would give effects similar to capillaries between rods. As to specific action of surfaces, chemical and physical treatment of rods and sheets may result in interesting effects.

The foregoing is a by-product of sea-water demineralization research on the Berkeley Campus of the University of California. Though the study of capillary filters is only at its beginning, realizing their potentiality in many fields, Prof. E. D. Howe, director of the project, authorized this publication.

A GENERAL CATION CARRIER IN THE YEAST CELL WALL

The General Carrier and its Amount per kgm. Yeast

It has been shown[1,2] that when yeast ferments 5 per cent glucose in the presence of potassium ions, they are taken up readily and in exchange for hydrogen ions. If there is no buffering outside and the volume of the suspending fluid approaches a minimum then the *p*H in this way can approach 1·5[3]. The uptake of potassium is much greater if the external fluid is buffered to a *p*H of 4·0–7·0. This exchange has been theoretically explained by the acceptance of metabolic hydrogen atoms by a metal catalyst in the cell wall, hydrogen ions being split off and electrons retained. The reduced catalyst then transports potassium ions internally[4,5].

It has been found that other ions besides potassium can be absorbed—sodium, for example[6], at a *p*H of about 6·0. The sodium had an affinity for the catalyst of about 0·04 that of the potassium ion. Not only sodium but also many other inorganic cations can be taken up by the carrier. The order of the affinities are: hydrogen, potassium, rubidium, cæsium, sodium, magnesium, calcium[7].

Magnesium ions can be taken up actively by the carrier in surprising amounts at a *p*H of 6·0–7·0 provided there is no other competing cation outside[8]. Thus in 7-hr. fermentation at room temperature with yeast in twenty times its volume of medium containing 5 per cent glucose and 0·2 *M* magnesium acetate, about 100 millimoles mgm. are taken up per kgm. yeast. The magnesium is taken up by the same carrier as potassium, as shown by the fact that as little as 0·5 m.equiv. potassium/litre outside can reduce the magnesium uptake from 200 m.equiv./litre by 50 per cent and a few m.equiv. can reduce it almost to zero. That magnesium should be taken up in this way is a property of the cation carrier and proceeds by a different mechanism from that occurring with phosphate at a *p*H of 4·0. In this case potassium facilitates the magnesium uptake[9]. Very probably the magnesium transport by the general cation carrier has no normal physiological significance since there will always be present more than enough potassium to inhibit it.

The same general cation carrier seems to be operative when external cations are being exchanged for the actively excreted sodium ions from a sodium-rich yeast (non-fermenting), the order of the affinities being in general very similar.

The actual concentration of the general cation carrier was measured from the amount of potassium instantaneously adsorbed by it and its subsequent displacement with excess of rubidium. The radioactive isotope potassium-42 was used for measuring the minute amounts of potassium so released into the external fluid. In the procedure adopted, yeast was suspended in 0·6 its volume of 5 per cent glucose containing 0·02 *M* magnesium acetate (to satisfy the anionic charges on the cell surface) and cooled to 4–5° C., a temperature at which potassium uptake is considerably reduced but is still measurable. Then labelled potassium chloride was added to produce a concentration in the suspending fluid of about 1 m.-equiv./litre, and after shaking vigorously for 30 sec. the potassium content of the supernatant was measured after centrifugation. To a similar suspension 30 sec. after addition of potassium, a very small volume of rubidium chloride solution was added to produce a Rb^+ concentration external to the cells of about 10 m.equiv./litre, and on shaking for a further half-minute the external potassium concentration was measured. The increase found was due to displacement of potassium from the carrier. The mean of thirteen such experiments gave 0·09 m.equiv. potassium displaced per kgm. yeast.

Since this method measured only the reduced form of the catalyst, the total concentration was measured by bubbling hydrogen through the suspension to remove all the oxygen present and so completely reduce the carrier. The potassium displacement, as a median for six experiments, was then found to be 0·12 m.equiv./kgm. It may be noted here that the difference between the amount of redox dye bound by the yeast in the completely reduced and completely oxidized conditions was approximately 0·15 m.equiv./kgm. yeast[10]. The iron content of yeast is about 0·60 m.equiv./kgm. wet yeast, mostly present in the cell wall[11], and the copper content about 0·06 m.equiv./kgm. Thus there is insufficient copper for binding the potassium but more than enough iron to act in the carrier enzyme.

Active Transport of Magnesium

The general cation carrier in the yeast cell wall, referred to in the foregoing communication, can transport large amounts of magnesium into the cell during fermentation, when magnesium is the only cation present (apart from H^+) in the suspending fluid, and this has a *p*H of about 7·0. Thus when 1 gm. of centrifuged baker's yeast is suspended in 20–100 ml. of 5 per cent glucose containing 0·2 *M* magnesium acetate, about 100 millimoles of magnesium are taken up in 7 hr. The Mg^{++} exchange for hydrogen ions in a similar way to the active uptake of K^+ [1,2].

When sodium is taken up in a similar way it can be actively excreted by the yeast cells when these are washed and suspended in water. The excretion rate is much increased if the suspending fluid contains 0·1 *M* potassium chloride. In the latter case, sodium exchanges for K^+. On the other hand, magnesium accumulated in such a manner is not appreciably excreted on subsequent suspension in water or potassium chloride solution, even when glucose is added to the extent of 5 gm. per 100 ml.

Although very large amounts of magnesium can be taken up in this way by the yeast cell, the process seems to have no physiological significance, for it is almost fully inhibited by 2 m*M* K^+ in the presence of 200 m*M* Mg^{++}.

There is another mode of active magnesium uptake which has been studied by Rothstein[3], and also by Schmidt, Hecht and Tannhauser[4]. This occurs at or near a *p*H of 4·5 in association with phosphate and is increased by the presence of K^+. It would appear to be the normal mode of magnesium uptake during fermentation.

The active transport of magnesium by the general cation carrier requires the presence of oxygen, though the uptake of potassium by the same carrier can occur anaerobically. This may by explained by the inability of the redox system, when carrying the divalent Mg^{++}, to transfer its electrons to the acceptor system in anaerobic yeast. The active transport is inhibited by cyanide and azide as well as by anoxia. Of considerable interest is the fact that the active transport of magnesium, when this is present as the acetate, is not inhibited by 2,4-dinitrophenol (2 m*M*). Thus the evidence indicates that this active transport of magnesium after its attachment to the initial redox carrier requires the cytochrome–oxygen system for the further transfer of electrons and release of the transported Mg^{++} into the cell.

A NEW METHOD FOR THE EXTRACTION OF DEOXYRIBONUCLEIC ACID FROM BACTERIA

By Dr. R. VENDRELY, C. PALMADE and C. VENDRELY

Centre de Recherches sur les Macromolecules, 6 rue Boussingault, Strasbourg

The extraction of deoxyribonucleic acid from bacteria, in a non-degraded state, raises some difficulties because of the presence around the bacterial body of resistant envelopes which prevent a rapid liberation in the medium of the molecules to be extracted. The method used by McCarty and Avery[1] consists of the lysis of the germs with sodium deoxycholate in the presence of sodium citrate as an inhibitor of deoxyribonuclease. This method yields a deoxyribonucleic acid highly polymerized and presenting a great biological specificity, but it is unfortunately limited to *Pneumococcus* and a very few other germs. The method of autolysis of bacteria, indicated by Boivin and Vendrely[2], allowed only the preparation of samples of deoxyribonucleic acid partially depolymerized. The methods, including mechanical processes of disruption of the germs (use of 'ball mills', shaking with glass beads, grinding with various abrasives)[3] are tedious and the yield is low and irregular.

We have devised a simple method for the extraction of bacterial deoxyribonucleic acid, using the lysozyme as a first step for the attack on the envelopes of the bacteria. This technique proved satisfactory for all

Table 1. RESULTS OF EXTRACTIONS OF DEOXYRIBONUCLEIC ACID FROM DIFFERENT BACTERIA

Germs	Time of action of the lysozyme (in min.)	Amounts of DNA released at the first extraction (in per cent of the total DNA)	No. of extraction	Amounts of DNA extracted at the end of the experiment (in per cent of the total DNA)	Percentage of the DNA collected in a fibrous form
Bacillus megatherium	6–10	45	2	90	100
	30	45	2	90	100
Proteus vulgaris	10	31	3	85	100
	10	25	3	62	100
	15	29	3	62	100
	45	—	3	62	70
Escherichia coli	6	45	3	80	100
	15	45	3	80	100
	30	45	3	80	100
Staphylococcus	3	30	2	50	90
	10	45	2	76	30
	30	45	2	80	0

the germs we have tried so far—*Bacillus megatherium*, several strains of *Proteus*, several strains of *Escherichia coli*, one of which was completely refractory towards the extraction by grinding.

The bacteria are grown for 12 hr. (*B. megatherium*) or 24 hr. (*Proteus*, *E. coli*, *Staphyloccocus*). They are collected and washed twice with physiological saline solution, then they are resuspended in water saturated with chloroform[4] and left for 30 min. in a cold room. The killed bacteria are then centrifuged in the refrigerated centrifuge and resuspended in a 4/1,000 solution of sodium chloride (pH 7·0)[5] in the proportion of 10 gm. of fresh bacteria for 100 c.c. of solution. Crystallized lysozyme is added (0·5 mgm. lysozyme to 1 c.c. of the suspension) and the suspension is incubated at room temperature (20° C.) for a time varying with the bacterium (3–15 min.). The action of the lysozyme is then stopped by rapid cooling at 2° C. and the bacteria are centrifuged in a refrigerated centrifuge, washed twice in distilled water in order to remove the lysozyme and the degraded polysaccharides and the supernatant are discarded—the residue is frozen at −30° C. overnight. The extraction of the deoxyribonucleic acid is then achieved by resuspending the frozen residue in ten times its volume of distilled water with glass powder (the weight of glass powder added is twice the weight of the residue) and shaking the suspension for 30 min. in a cold room. (Other abrasives such as quartz powder, aluminium oxide, are not so efficient as glass powder.) The suspension is then centrifuged at low temperature, and the supernatant containing the deoxyribonucleic acid is collected. This operation must be repeated three or four times until nearly total extraction of the deoxyribonucleic acid is achieved. The solution of deoxyribonucleic acid collected each time is very viscous and little coloured; it is precipitated immediately by addition of three volumes of 95° alcohol. Repeated dissolutions and reprecipitations give a good purification of the deoxyribonucleic acid, though further purification can be attained by one of the methods described by Zamenhof *et al.*[6,7].

Table 1 shows the results of the different experiments performed.

The most important step in this method is obviously the treatment of the bacteria with lysozyme. This enzyme, destroying the polysaccharides of the bacterial envelopes, allows the dissolution of the deoxyribonucleic acid in the medium together with other substances of the bacterial body (ribonucleic acid, proteins). The chloroformed water, by killing the bacteria, makes the action of lysozyme easier.

Freezing makes the bacteria more fragile and increases their permeability, and shaking with glass powder facilitates the solution of the deoxyribonucleic acid by dissociation of the gel and adsorption of the deoxyribonucleic acid on the surface of the glass particles. The results summarized in Fig. 1 are quite significant: it can be seen, for example, that if the action of lysozyme is omitted, almost no deoxyribonucleic acid can be extracted. Concerning the time of action of lysozyme, there is a threshold which is not the same for the different bacteria: 6 min. for *E. coli*, 10 min. for *Proteus*, 3–10 min. for *Megatherium*, 3 min. for *Staphylococcus*. Beyond this threshold, the yield remains the same for longer times, so there is no need to use longer times of action for lysozyme.

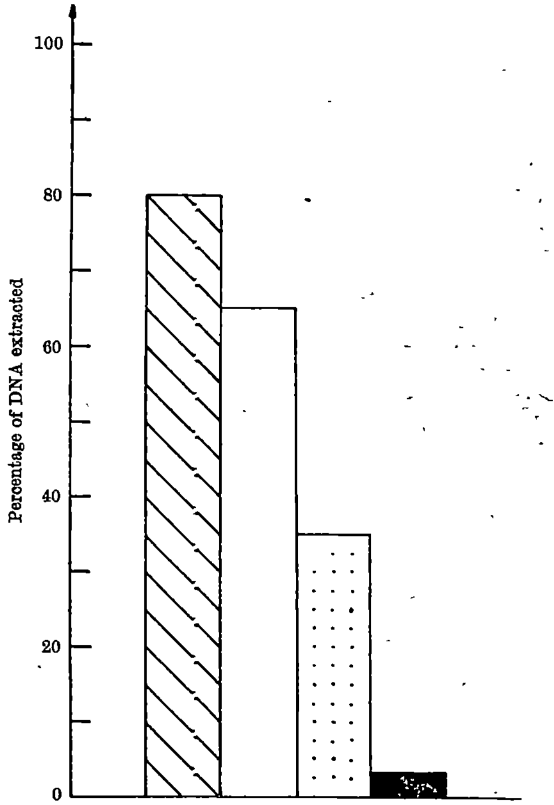

Fig. 1. Histogram showing the yield of the method for the extraction of deoxyribonucleic acid from bacteria (experiment performed on *Escherichia coli*) when various steps are omitted. Striped: optimal conditions. Plain: when germs are not frozen. Stippled: when chloroform is omitted. Black: when lysozyme is omitted

Moreover, the risk of autolysis is greater for long times and, in that case, the deoxyribonucleic acid extracted is no longer entirely polymerized. This fact is particularly striking in *Staphylococcus*, the deoxyribonucleic acid of which depolymerizes very rapidly in the course of extraction.

The degree of polymerization of the final product can be roughly estimated by considering the more or less fibrous state of the precipitate and the viscosity of the solution. When the method is used in optimal conditions, the yield of deoxyribonucleic acid is excellent. We have been able to extract 70–90 per cent of the acid contained in bacteria.

A TEST OF A NEW TYPE OF STELLAR INTERFEROMETER ON SIRIUS

By R. HANBURY BROWN
Jodrell Bank Experimental Station, University of Manchester
AND
Dr. R. Q. TWISS
Services Electronics Research Laboratory, Baldock

We have recently described[1] a laboratory experiment which established that the time of arrival of photons in coherent beams of light is correlated, and we pointed out that this phenomenon might be utilized in an interferometer to measure the apparent angular diameter of bright visual stars.

The astronomical value of such an instrument, which might be called an 'intensity' interferometer, lies in its great potential resolving power, the maximum usable base-line being governed by the limitations of electronic rather than of optical technique. In particular, it should be possible to use it with base-lines of hundreds, if not thousands of feet, which are needed to resolve even the nearest of the *W*-, *O*- and *B*-type stars. It is for these stars that the measurements would be of particular interest since the theoretical estimates of their diameters are the most uncertain.

The first test of the new technique was made on Sirius (α Canis Majoris A), since this was the only star bright enough to give a workable signal-to-noise ratio with our preliminary equipment.

The basic equipment of the interferometer is shown schematically in Fig. 1. It consisted of two mirrors M_1, M_2, which focused light on to the cathodes of the photomultipliers P_1, P_2 and which were guided manually on to the star by means of an optical sight mounted on a remote-control column. The intensity fluctuations in the anode currents of the photomultipliers were amplified over the band 5–45 Mc./s., which excluded the scintillation frequencies, and a suitable delay was inserted into one or other of the amplifiers to compensate for the difference in the time of arrival of the light from the star at the two mirrors. The outputs from these amplifiers were multiplied together in a linear mixer and, after further amplification in a system where special precautions were taken to eliminate the effects of drift, the average value of the product was recorded on the revolution counter of an integrating motor. The readings of this counter gave a direct measure of the correlation between the intensity fluctuations in the light received at the two mirrors; however, the magnitude of the readings depended upon the gain of the equipment, and for this reason the r.m.s. value of the fluctuations at the input to the correlation motor was also recorded by a second motor. Since the readings of both revolution counters depend in the same manner upon the gain, it was possible to eliminate the effects of changes in amplification by expressing all results as the ratio of the integrated correlation to the r.m.s. fluctuations, or uncertainty in the final value. The same procedure was also followed in the laboratory experiment described in a previous communication[1].

There is no necessity in an 'intensity' interferometer to form a good optical image of the star. It is essential only that the mirrors should focus the light from the star on to a small area, so that the photocathodes may be stopped down by diaphragms to the point where the background light from the night sky is relatively insignificant. In the present case, the two mirrors were the reflectors of two standard searchlights, 156 cm. in diameter and 65 cm. in focal length, which focused the light into an area 8 mm. in diameter. However, for observations of Sirius, the circular diaphragms limiting the cathode areas of the photomultipliers (*R.C.A.* type 6342) were made as large as possible, namely, 2·5 cm. in diameter, thereby reducing the precision with which the mirrors had to be guided.

The first series of observations was made with the shortest possible base-line. The searchlights were placed north and south, 6·1 metres apart, and observations were made while Sirius was within 2 hr. of transit. Since the experiments were all carried out at Jodrell Bank, lat. 53° 14′ N., the elevation of the star varied between 15½° and 20°,

Table 1. COMPARISON BETWEEN THEORETICAL AND OBSERVED CORRELATION

1. Base-line in metres	2·5 (N.S.)	5·54 (E.W.)	7·27 (E.W.)	9·20 (E.W.)
2. Observing time (min.)	345	285	280	170
3. Observed ratio of integrated correlation to r.m.s. deviation: $C(d)$	+8·50	+3·59	+2·65	+0·83
4. Theoretical ratio of integrated correlation to r.m.s. deviation, assuming star has an angular diameter of 0·0063″: $C(d)$	+9·35	+4·11	+2·89	+1·67
5. Theoretical ratio of integrated correlation to r.m.s. deviation, assuming star is a point source: $C(o)$	+10·15	+5.63	+5·06	+4·40
6. Theoretical normalized correlation coefficient for star of diameter 0·0063″. $\Gamma^2(d)$	0·92	0·73	0·57	0·38
7. Observed normalized correlation coefficient with associated probable errors: $\Gamma^2(d)$	0·84 ± 0·07	0·64 ± 0·12	0·52 ± 0·13	0·19 ± 0·15

and the average length of the base-line projected normal to the star was 2·5 metres; at this short distance Sirius should not be appreciably resolved.

Throughout the observations the average d.c. current in each photomultiplier was recorded every 5 min., together with the readings of the revolution counters on both the integrating motors. The small contributions to the photomultiplier currents due to the night-sky background were measured at the beginning and end of each run. The gains of the photomultipliers were also measured and were found to remain practically constant over periods of several hours.

In order to ensure that any correlation observed was not due to internal drifts in the equipment, or to coupling between the photomultipliers or amplifier systems, dummy runs of several hours duration were made before and after every observation; for these runs the photomultiplier in each mirror was illuminated by a small lamp mounted inside a detachable cap over the photocathode. In no case was any significant correlation observed.

In this initial stage of the experiment, observations were attempted on every night in the first and last quarters of the Moon in the months of November and December 1955; the period around the full moon was avoided because the background light was then too high. During these months a total observation time of 5 hr. 45 min. was obtained, an approximately equal period being lost due to failure of the searchlight control equipment. The experimental value for the integrated correlation $C(d)$ at the end of the observations is given in the line 3 of Table 1. The value of $C(d)$ is the ratio of the change in the reading of the counter on the correlation motor to the associated r.m.s. uncertainty in this reading.

In the second stage of the experiment the spacing between the mirrors was increased and observations were carried out with east–west base-lines of 5·6, 7·3 and 9·2 metres. These measurements were made on all possible nights during the period January–March 1956, and a total observing time of 12¼ hr. was obtained. The observed values of the integrated correlation $C(d)$ are shown in line 3 of Table 1.

As a final check that there was no significant contribution to the observed correlation from any other source of light in the sky, such as the Čerenkov component from cosmic rays[2], a series of observations was made with the mirrors close together and exposed to the night sky alone. No significant correlation was observed over a period of several hours.

The results have been used to derive an experimental value for the apparent angular diameter of Sirius. The four measured values of $C(d)$ were compared with theoretical values for uniformly illuminated disks of different angular sizes, and the best fit to the observations was found by minimizing the sum of the squares of the residuals weighted by the observational error at each point. In making this comparison, both the angular diameter of the disk and the value of $C(o)$, the correlation at zero base-line, were assumed to be unknown, and account was taken of the different light flux and observing time for each point. Thus the final experimental value for the diameter depends only on the relative values of $C(d)$ at the different base-lines, and rests on the assumption that these relative values are independent of systematic errors in the equipment or in the method of computing $C(d)$ for the models. The best fit to the observations was given by a disk of angular diameter 0·0068″ with a probable error of ± 0·0005″.

The angular diameter of Sirius, which is a star of spectral type $A1$ and photovisual magnitude −1·43, has never been measured directly; but if we assume that the star radiates like a uniform disk and that the effective black body temperature[3,4] and bolometric correction are 10,300° K. and −0·60, respectively, it can be shown that the apparent angular diameter is 0·0063″, a result not likely to be in error by more than 10 per cent. (In this calculation the effective temperature, bolometric magnitude and apparent angular diameter of the Sun were taken as 5,785° K., −26·95, and 1,919″, respectively.) Thus it follows that the experimental value for the angular diameter given above does not differ significantly from the value predicted from astrophysical theory.

A detailed comparison of the absolute values of the observed correlation with those expected theoretically has also been made, and the results are given in Table 1 and in Fig. 2. In making this com-

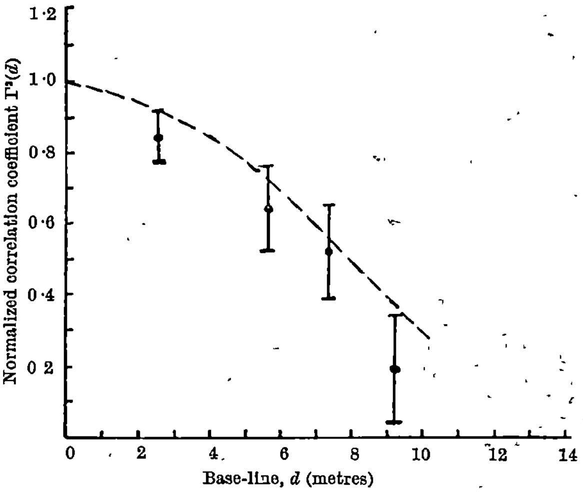

Fig. 2. Comparison between the values of the normalized correlation coefficient $\Gamma^2(d)$ observed from Sirius and the theoretical values for a star of angular diameter 0·0063″. The errors shown are the probable errors of the observations

parison, it is convenient to define a normalized correlation coefficient $\Gamma^2(d)$, which is independent of observing time, light flux and the characteristics of the equipment, where $\Gamma^2(d) = C(d)/C(o)$ and $C(d)$ is the correlation with a base-line of length d, and $C(o)$ is the correlation which would be observed with zero base-line under the same conditions of light flux and observing time. The theoretical values of $\Gamma^2(d)$ for a uniformly illuminated disk of diameter 0·0063″ are shown in line 6 of Table 1. For monochromatic radiation it is simple to evaluate $\Gamma^2(d)$, since it can be shown[5] that it is proportional to the square of the Fourier transform of the intensity distribution across the equivalent strip source; however, in the present case, where the light band-width is large, the values of $\Gamma^2(d)$ were calculated by numerical integration.

The theoretical values of $C(o)$, given in line 5, were calculated for the conditions of light flux and observing time appropriate to each base-line by means of equations (1) and (2) of our previous communication[1] (though in the present experiment the r.m.s. fluctuations were smaller by a factor $1/\sqrt{2}$ than the value given in the previous paper, which refers to an alternative electronic technique). The most important quantities in this calculation are the gains and output currents of the photomultipliers and the band-widths of the amplifiers; but it is also necessary to make a small correction for the combined spectral characteristics of the photocathodes, the atmospheric attenuation, the star and the mirrors. Finally, in line 4 of Table 1 the theoretical values of the correlation $C(d)$ are shown; they were calculated from the theoretical values of $C(o)$ and $\Gamma^2(d)$ by means of the relation given above.

The correlation observed at the shortest base-line (2·5 m.) can be used as a rough test of the effects of atmospheric scintillation on the equipment, since the corresponding theoretical value depends only on well-known quantities and is almost independent of the angular diameter of the star. Throughout the observations Sirius was seen to be scintillating violently, although the corresponding fluctuations in the d.c. anode currents of the photomultiplier tubes, which were smoothed with a time constant of about 0·1 sec., were only of the order of ± 10 per cent, as might be expected with mirrors large by normal telescope standards. Nevertheless, the observed correlation $C(d) = +\,8{\cdot}50$ does not differ significantly from the calculated value of $+\,9{\cdot}35$, and it follows that it cannot be greatly affected by scintillation.

The experimental values of $C(d)$ obtained at the four base-lines may be compared with the corresponding theoretical values $C(d)$ by means of lines 3 and 4 of Table 1. However, it is more convenient, since these values depend upon the different values of observing time and light flux at each base-line, to normalize the observed values of $C(d)$ by the corresponding values of $C(o)$, so as to give the normalized correlation coefficients $\Gamma^2(d)$ shown in line 7. In Fig. 2 these experimental values of $\Gamma^2(d)$ are shown together with their probable errors, and may be compared with the broken curve, which gives the theoretical values for a uniform disk of 0·0063″. It can be seen that both the relative and absolute values of $\Gamma^2(d)$ are in reasonable agreement with theory, and that within the rather wide limits of this preliminary test there is no significant difference between the correlation predicted and observed.

In assessing the potentialities of the technique described here, it is important to note that, although the measurements took five months to complete, the visibility was so poor that the total observing time was only 18 hr., while in this limited period additional absorption of 0·25–0·75 magnitudes due to haze or thin cloud was often present. If the observations had been made at a latitude where Sirius transits close to the zenith, the improved signal-to-noise ratio, due to decreased atmospheric absorption, would have made it possible to obtain the same data in a total observing time of about four hours.

Thus, despite their tentative nature, the results of this preliminary test show definitely that a practical stellar interferometer could be designed on the principles described above. Admittedly such an instrument would require the use of large mirrors. Judging from the results of this test experiment, where the peak quantum efficiency of the phototubes was about 16 per cent and the overall band-width of the amplifiers was about 38 Mc./s., one would need mirrors at least 3 metres in diameter to measure a star, near the zenith, with an apparent photographic magnitude + 1·5. Mirrors of at least 6 metres in diameter would be required to measure stars of mag. +3, and an increase in size would also be needed for stars at low elevation because of atmospheric absorption. However, the optical properties of such mirrors need be no better than those of searchlight reflectors, and their diameters could be decreased if the overall band-width of the photomultipliers and the electronic apparatus could be increased, or if photocathodes with higher quantum efficiencies become available. It must also be noted that the technique of using two mirrors, as described here, would probably be restricted to stars of spectral type earlier than *G*, since cooler stars of adequate apparent magnitude would be partially resolved by the individual mirrors.

The results of the present experiment also confirm the theoretical prediction[6] that an 'intensity' interferometer should be substantially unaffected by atmospheric scintillation. This expectation is also supported by experience with a radio 'intensity' interferometer[5,7,8] which proved to be virtually independent of ionospheric scintillation. It is also to be expected that the technique should be capable of giving an extremely high resolving power. Without further experience it is impossible to estimate the maximum practical length of the base-line; however, it is to be expected that the resolving power could be at least one hundred times greater than the highest value so far employed in astronomy, and that almost any star of sufficient apparent magnitude could be resolved.

We thank the Director of Jodrell Bank for making available the necessary facilities, the Superintendent of the Services Electronics Research Laboratory for the loan of much of the equipment, and Dr. J. G. Davies for his assistance with setting up the searchlights. One of us (R. Q. T.) wishes to thank the Admiralty for permission to submit this communication for publication.

Time Courses of Motoneuronal Responses

THERE is now much experimental evidence supporting the postulate that excitatory and inhibitory synaptic actions are effective by the potential changes that are set up across the motoneurone membrane[1,2], the excitatory post-synaptic potential and the inhibitory post-synaptic potential being respectively in the depolarizing and hyperpolarizing directions. When generated by a virtually synchronous synaptic bombardment, these potential changes are approximately mirror images, the brief rising phases being followed by slower decays (Fig. *Aa*, *b*).

Further, it may be postulated that the subsynaptic currents (cf. inset, Fig. *B*) generating these potential changes have the same time courses as the synaptic transmitter substances that are responsible for them. Hitherto the time courses of action of the respective transmitters have been derived from analyses based upon the assumption that the approximate exponential decays of the excitatory and inhibitory post-synaptic potentials are determined by the passive decay of the charge that has been placed on the membrane capacity during the brief phase of transmitter action. It is known that the end-plate potential at the amphibian neuromuscular junction decays with the same time constant as that of the muscle membrane[3], and, as the time constants of decay of the excitatory and inhibitory post-synaptic potentials were considered to be approximately equal, it was argued that the electrical time constant of the motoneuronal membrane was the same as that of the decay of either type of post-synaptic potential, namely, approximately 4 msec.[4]. However, more accurate investigations, depending on the use of pure excitatory and inhibitory volleys, show that, while the time constant of decay of the excitatory post-synaptic potential is approximately 4·7 msec., that of the inhibitory post-synaptic potential is usually about 3·0 msec. (cf. Fig. *Aa*, *b*). Hence the time constant of the motoneuronal membrane cannot be derived by the above indirect procedure, and it becomes necessary to redetermine the electrical time constant of the membrane by more direct methods.

Motoneurones were impaled with double-barrelled micro-electrodes[1] filled with 0·6 *M* potassium sulphate solution, and the electrical properties of the membrane were determined by examining its response to rectangular current pulses passed through one barrel of the microelectrode. The consequent potential changes were recorded by means of the other barrel, using a cathode-follower input-stage the output of which was applied to one input of a differential

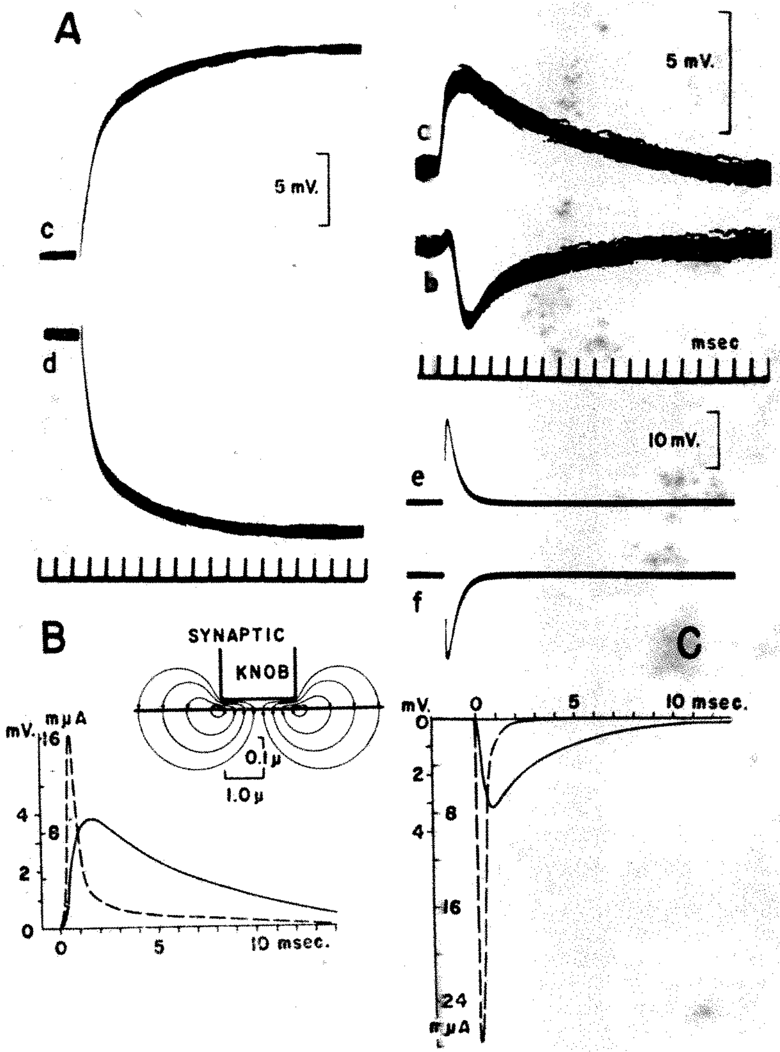

Fig. *A*. Potentials recorded from a biceps-semitendinosus motoneurone with a double microelectrode, both barrels being filled with 0·6 *M* potassium sulphate solution. Each record consists of forty superimposed traces. (*a*) Excitatory post-synaptic potential generated monosynaptically. (*b*) Inhibitory post-synaptic potential generated by impulses in the group I*a* afferent fibres from the quadriceps muscle. (*c*) and (*d*) Potentials generated immediately afterwards by rectangular current pulses of 12 × 10^{-9} amp. which are in the depolarizing and hyperpolarizing directions respectively. As shown in the extracellular records (*e* and *f*), the compensating network virtually eliminated all potential changes except those within 1·5 msec. after the onset of the pulse. The currents in *e* and *f* were 12 × 10^{-9} amp. in both the depolarizing and hyperpolarizing directions. Time constant values for this cell were higher than average, the membrane time constant derived from *c*, *d*, *e* and *f* being 3·1 msec. The excitatory post-synaptic potential decayed with a time constant of 5·5 msec. and the inhibitory post-synaptic potential with a time constant of 3·5 msec.

Fig. *B*. The continuous line is the mean of the monosynaptic excitatory post-synaptic potentials of Fig. *Aa*; ordinate in mV. The broken line shows the time course of the subsynaptic current required to generate this potential change derived by using the measured values of 3·1 msec. and 2·4 × 10^{-9} *F*. for the time constant and capacity of the membrane; ordinate scale in mμamp. The inset shows the direction of the subsynaptic current flow for an excitatory synaptic ending.

Fig. *C*. The continuous line is the mean of the 'direct' inhibitory post-synaptic potentials of the same cell (Fig. *A*,*b*). The time course of the subsynaptic current required to generate this potential change has been determined as in Fig. *B* and plotted by the broken line. It is of opposite sign, so would run in a direction opposite to that shown in the inset of Fig. *B* amplifier. The difficulties caused by the resistive and capacitative couplings between the two barrels were largely overcome by applying the same rectangular pulses to an electrical network, which was adjusted to reproduce similar artefacts to those of the double microelectrode alone and which fed this signal to the second input of the differential amplifier. In this way it was possible to balance out almost all the artefact generated in the electrode. For any one cell, potentials due to the current pulses were recorded both intra- and extra-cellularly without altering the balance network (Fig. *A*,*c*, *e* and *d*, *f*). Subtraction of these potentials for any one value of current gives the magnitude and time course of the membrane potential produced by this current pulse.

As determined in this manner, the membrane potential attained its new value with an approximately exponential time course, the time constant being about 2·5 msec., which may be taken to be the electrical time constant of the motoneurone membrane. Using this value, it has been possible to analyse the excitatory and inhibitory post-synaptic potentials on the basis of Hill's local potential theory[5,6], and to determine the time courses of the respective subsynaptic currents (Figs. *B*, *C*) and hence of the transmitter actions. Both transmitters have an initial intense phase of action. Contrary to previous accounts[2], a residuum of excitatory transmitter persists during the decaying phase of the excitatory post-synaptic potential (Fig. *B*). A smaller residuum is usually observed for the inhibitory transmitter, but sometimes it is negligible (Fig. *C*).

Independent confirmation of the prolonged residuum of excitatory transmitter action has been provided by firing an antidromic impulse into a motoneurone at varying times during a monosynaptic excitatory post-synaptic potential, which is thereby destroyed[2]. If the antidromic impulse so acts even several milliseconds after the onset of the excitatory post-synaptic potential, a very small rebuilding of that potential occurs after the antidromic spike potential, which was previously overlooked[2], and which must be attributable to a small residuum of excitatory transmitter action.

Cardiac Repolarization and Metabolic Blockade

ADRIAN[1] in 1921 showed that monophasic action potentials of the frog heart lasted up to 2 sec. at 14·5° C. and corresponded to the refractory period which normally protects the heart from erratic beating. He found that the action potential of a premature beat was shorter in duration than the preceding action potential. Measurements with intracellular electrodes have confirmed these findings ; but no adequate explanation for the prolonged action potential of heart cells is available. Weidmann[2] has shown that the plateau of the action potential is a period of low conductance. He has suggested three types of change of K^+ or Na^+ permeability to account for this delay in repolarization. None of these hypotheses is quite satisfactory, so the problem has been approached by using metabolic blocking agents.

The plateau of depolarization in isolated frog atrium and ventricle is reversibly reduced in duration to about one-third of its normal length (Fig. 1*b*) by the action of 2 : 4-dinitrophenol at a concentration of 0·2 m.mole/l. [3]. Higher concentrations irreversibly shorten the action potential to one-sixth of its normal length. Sodium azide and neutral red, both of which interfere with oxidative phosphorylation, also reduce the duration of the plateau. Hypoxia acts in a similar fashion. The plateau appears to be linked, therefore, with supplies of high-energy phosphate. Further evidence for the dependence of recovery upon supplies of energy comes from the high-temperature coefficient of the plateau (Q_{10} 4–5)[4] and from the behaviour of the heart during extrasystoles and tachycardia. By driving excised amphibian hearts at different rates and recording intracellularly (Fig. 2), it was found that the rest pause coming before any action potential determines the duration of the next plateau of depolarization. In addition, the rate of depolarization becomes slower and the overshoot less, as the rest between beats is reduced. The relation between antecedent electrical diastole and the time of repolar-

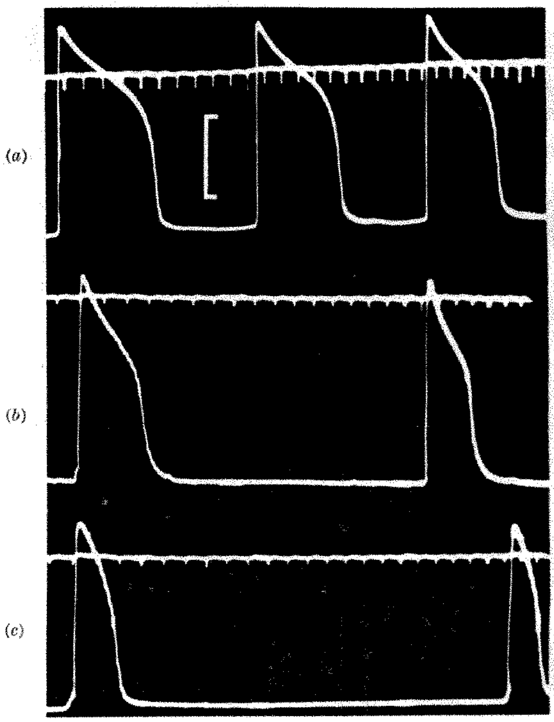

Fig. 1. Intracellular records of excised frog ventricle fibres at 22° C., beating spontaneously. (*a*) In normal Ringer solution, action potential duration 540 msec. and electrical diastole 360 msec.; (*b*) 10 min. in 0·2 m.mole/l. 2 : 4-Dinitrophenol + Ringer solution. Plateau shortened : action potential 320 msec., but rest pause 1,400 msec. ; (*c*) 30 min. in 0·2 m.mole/l. 2 : 4-dinitrophenol. Action potential 210 msec., pause 1,960 msec., resting potential reduced by 6 per cent. 2 : 4-Dinitrophenol reduces the time of repolarization, and a long diastolic pause does not assist recovery of the plateau. (Time marks 100 msec., voltage 50 mV.)

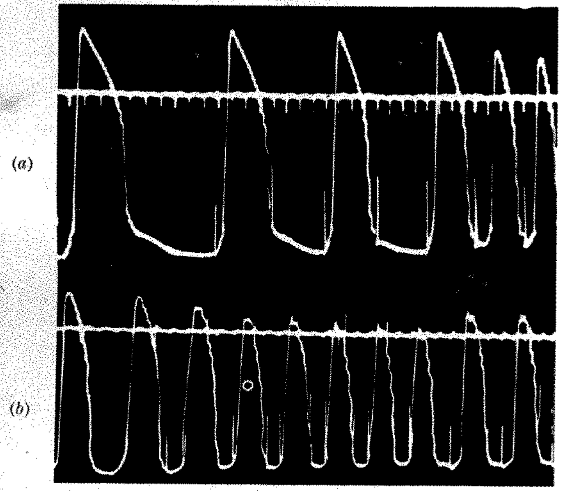

Fig. 2. Excised frog heart at 22° C. (a) Intracellular action potential of ventricle fibre. First potential shows fatigue after being driven, and action potential lasts only 350 msec. after 600 msec. rest; then driven at 2/sec. Shorter rest pause followed immediately by shorter action potential. (b) Drive 10/sec. with heart following each third and fourth stimulus. Reduced voltage and duration of action potential. (Time 100 msec.)

ization of the following action potential is linear in fresh hearts. The return of a long plateau after an exhausting period of fast activity is delayed, however, for several minutes (Fig. 2a), so the regression line then becomes a hysteresis loop. This behaviour may be interpreted as the restoration during electrical inactivity of specific energy sources to maintain the next plateau. When 2 : 4-dinitrophenol shortens the plateau of depolarization, however, a long rest is ineffective in prolonging the action potential (Fig. 1c).

Active transport of K^+ into nerve cells has been detected[5]. It is blocked by cyanide, 2 : 4-dinitrophenol and sodium azide. Acetylcholine shortens the plateau of heart fibres innervated by the vagus[6] and increases K^+ efflux[7]. None of these events, however, seems to provide a complete picture of the mechanism of the plateau. Active outward transport of such an anion as Cl^- offers a better, as yet untested, explanation. The plateau of the action potential is a period of low conductance, and it appears to be dependent on supplies of energy from oxidative phosphorylation which presumably are required for active ion transport. There is no conclusive evidence that the active ion transfer involves K^+ influx or Cl^- extrusion. Following the plateau, outward diffusion of K^+ would increase conductance and restore the membrane potential, though there may also be some active ion transport in this rather slow recovery phase.

Essential Fatty Acid Activity of Docosapolyenoic Acids from Brain Glycero-Phosphatides

PREVIOUS work[1] has suggested that the presence of double bonds at the 6–7, 9–10 positions, counting from the terminal CH_3-group, is fundamental for the biological activity of essential fatty acids. This '6 : 9-(term.)'-hypothesis has directed attention to the highly unsaturated long-chain fatty acids from brain glycero-phosphatides[1]. According to Klenk[2], the C_{20} fatty acids of these phosphatides should contain two C 6,9-(term.)-acids, namely, C 11,14-eicosadienoic acid and arachidonic acid. The latter has long been recognized as an essential fatty acid, and, more recently, the former has appeared to be also active[1]. In the C_{22}-fraction of the brain glycero-phosphatides, six different fatty acids should occur, three possessing the 6,9-(term.)-configuration. Later, Klenk[2] succeeded in verifying the presence of these three 6,9-(term.)-acids by isolation and identification:

	Location of double bonds (terminal numbering)
C 7,10,13,16-tetraenoic acid	6, 9, 12, 15
C 4,7,10,13,16-pentaenoic acid	6, 9, 12, 15, 18
C 4,7,10,13,16,19-hexaenoic acid	3, 6, 9, 12, 15, 18

According to the theory, these acids should be active as essential fatty acids. In order to verify this supposition, fractions of highly unsaturated C_{22}-fatty acids from human brain glycero-phosphatides were tested for their bio-potency.

The isolation of these docosapolyenoic acids was carried out by one of us (H. de I.) under the guidance of Prof. E. Klenk at the Institute for Physiological Chemistry, University of Cologne, using a slight modification of Klenk's method[2] which involved the following steps: (1) dehydration of the brain and extraction with acetone; (2) extraction with ether of the phosphatides; (3) methanolysis of the phosphatides; (4) saponification of the methyl esters to fatty acids; (5) fractional crystallization by deep-freezing of the fatty acids in acetone solution; (6) esterification of the unsaturated fatty acids; (7) high-vacuum distillation of the ethyl esters, in order to separate the C_{18}-, C_{20}- and C_{22}-fractions.

In order to reduce losses on the walls and packing of the column, some paraffin oil (boiling point 160–190° C. at 10^{-4} mm. mercury) was added to the highly unsaturated fatty acid-ethyl esters prior to distillation. Eight fractions containing C_{22}-ethyl esters were collected (see Table 1).

It will be seen from Table 1 that the percentage unsaponifiable is fairly high. Very probably this is comprised entirely of the paraffin oil which was added prior to distillation.

Table 1. DATA OF THE INDIVIDUAL C_{22}-FRACTIONS

Fraction No.	Unsaponifiable (per cent)	Iodine value*	Conjugated dienes (per cent)	Conjugated trienes (per cent)
1	6	267		
2	6	293	1·5	—
3	9	293		
4	11	279	2·7	—
5	13	270		
6	16	268	6·9	0·1
7	16	246		
8	26	234	6·8	0·7

* The iodine values were determined by the method of Rosenmund and Kuhnheim and corrected for the percentage of the fractions which could not be saponified.

Table 2. Melting Points and Equivalent Weights of the Hydrogenated and Saponified Fractions

Hydrogenated fraction No.	Melting point (° C.)	Equivalent weight
1	77·0–79·0	354
2	78·0–80·0	341
3	78·0–80·0	340
4	79·0–80·5	339
5	80·0–80·5	339
6	78·5–79·5	339
7	75·5–76·0	346
8	75·0–75·5	349

Conjugated double bonds are present to a small degree, probably formed during distillation. Moreover, the corrected iodine values are somewhat lower than could be expected from the values found previously by Klenk[2].

To ascertain the purity of the fractions a small part of each fraction was hydrogenated, saponified and freed from the unsaponifiable portion, and after recrystallization of the fatty acids from acetone, their melting points and equivalent weights were determined.

As the melting point of behenic acid is theoretically 79·9–80·0° C. and its equivalent weight 340, it appears that fractions 2–6 consist of almost pure behenic acid.

The fractions were assayed in accordance with the method customarily used in this laboratory[1]. Some modifications were made. In order to avoid oxidation of the strongly unsaturated acids the animals (male Wistar rats) were given the total dose in one application instead of the usual daily dosing, the suitability of this depot method having been tested in preliminary experiments (unpublished work). For the same reason each animal was given 3 mgm. α-tocopherol (dissolved in 0·1 ml. of the ethyl esters of hardened coconut fatty acids). The ethyl esters of sunflower-seed oil fatty acids diluted with the ethyl esters of hardened coconut fatty acids were employed as a reference standard. The presence of paraffin oil in the distillate fractions might be an interfering factor; but one of the reference standards contained 10 per cent paraffin oil. It appeared, however, that paraffin oil in such small amounts did not influence the response.

As a unit for the bio-potency, the effect of 10 mgm. linoleic acid was taken[1]. The linoleic acid content of the reference standard was determined spectrophotometrically. The results of the bio-assay of the fractions are collected in Table 3.

The C_{20} fractions containing the highly active arachidonic acid and the weakly active[1] C 11,14-diene have a mean potency of 80 units/gm. The C_{22}-fractions, although somewhat less active than the preceding ones, also show a (significant) potency (mean : 38 units/gm.).

Table 3. Bio-potency of the Highly Unsaturated Fractions of Ethyl Esters of C_{20} and C_{22} Fatty Acids of Brain Glycerophosphatides

Fraction		Bio-potency (units/gm.)
A	C_{20}	100
B		62
C	$C_{20} + C_{22}$	78
1	C_{22}	48
2		52
3		30
4		39
5		36
6		23
7	C_{22} + traces C_{24}	40
8		50

In 1938 Hume[3] assayed a C_{22}-fraction obtained from cod-liver oil. The test animals showed only a slight positive reaction: their weights increased, but the skin lesions did not heal. Possibly a structural difference exists between the docosapolyenoic acids from the brain glycero-phosphatides of mammals and similar acids from fish oils[4].

Beauvallet[5] showed that the hexaene content of the brains of rats decreases by about 50 per cent when the animals receive fat-free diets. The present results are in accord with the theory that a relationship exists between the essential fatty acids and the central nervous system. Moreover, they furnish strong support for the 6,9-(term.)-hypothesis.

Our thanks are due to the advice and hospitality of Prof. E. Klenk, to Mr. Sparreboom for the spectrophotometric determinations and to the management of Unilever N.V. for permission to publish this communication.

Factor I and γ-Aminobutyric Acid

Extracts of brain and spinal cord of mammals inhibit impulse generation in stretch receptor neurons of the crayfish[1]. The substance or substances responsible for this action has been referred to as Factor I[1]. In mammals this factor is present only in the central nervous system[1,2]. Partially purified preparations of the Factor have been found to imitate the action of inhibitory neurons in crustaceans[1,3] and to block synaptic transmission in autonomic ganglia[2] and monosynaptic spinal reflexes[4] of mammals. Factor I preparations were also found to activate the hypoglossal nucleus and often to stimulate polysynaptic spinal reflexes[4]. The inhibitory effects of Factor I in the spinal cord could be prevented by a subconvulsive dose of strychnine[4]. Partial purifications of Factor I have been obtained[1,2,4] by taking advantage of the observations that the factor is thermostable, dialysable, stable to acid and alkali, not precipitated by lead acetate or perchloric acid, soluble in methanol, moderately soluble in ethanol and insoluble in other organic solvents.

Factor I has now been found to be present in an occult, inactive condition in brain from which it can be released by heat, hypotonicity, or mild acid or alkali. Its production by brain is indicated by the fact that the activity found in brain suspensions increases with time. It has previously been reported that brain tissue can inactivate the factor[1]. The inhibitory effect of Factor I on the crayfish stretch receptor can be prevented by picrotoxin and metrazol, which are convulsants in the crayfish, but not by strychnine or camphor, which are not convulsants in this animal. These observations and those referred to above suggest that Factor I may be a transmitter substance of inhibitory neurons and that interference with its action may be the basis of the convulsive effects of some drugs.

A convenient and rather accurate method of assay of Factor I has recently been developed using the crayfish stretch receptor as test object. This assay has been used in work on the isolation of substances which exhibit Factor I activity. Acetone-dried beef brain was extracted with 70 per cent ethanol. The evaporated extract was precipitated with acetone, washed with petrol ether and re-extracted with 95 per cent ethanol, and the ethanol was removed. Taking advantage of the fact that the active material underwent exchange with both strong acid and strong base ion-exchange resins, but not with either weak acid or weak base resins, a purified fraction was obtained which crystallized on evaporation from the water solution, and which represented a one-thousand-fold concentration of the activity over that of acetone-dried brain.

Fractional crystallization of this material has yielded three crystalline substances. Out of ethanol, on slow evaporation, clear, striated, rhomboid plates were obtained which showed the highest Factor I activity of any material yet encountered. A concentration of about 2 μgm. per ml. was sufficient to block the activity of the crayfish stretch receptor neuron. This material was identified with γ-aminobutyric acid by infra-red analysis, melting point, and paper chromatography. An authentic sample of γ-aminobutyric acid was found to have the same activity when assayed on the stretch receptor preparation. Two other types of crystals were obtained from acetone-water but have not been identified. One of these—needle clusters—was active and may be γ-aminobutyric acid; the other type—rod-shaped crystals—was inactive. The residue from the 95 per cent ethanol extraction retained an amount of activity approximately equal to that which dissolved in the ethanol. This activity, readily soluble in water, did not undergo exchange with either strong acid or strong base resins. The nature of this fraction is not yet known.

Among many α-amino-acids and other substances of biochemical interest which have been tested, only one was found to show Factor I activity. This was β-alanine, which was about one-twentieth as active as γ-aminobutyric acid.

The activity of Factor I is thus apparently the composite effect of several different substances. It is possible that the ethanol-insoluble fraction may be a complex or modification of γ-aminobutyric acid. The activity of β-alanine is low and may not be of physiological significance; its activity is presumably a result of its close structural similarity to γ-aminobutyric acid. Preliminary studies by Dr. Elizabeth Florey indicate that the content of Factor I activity in different regions of beef brain varies widely. The average activity of whole cerebral hemispheres from rats corresponds to that of about 200 mgm. of γ-aminobutyric acid per kilogram. Tentative estimates by Awapara *et al.*[5] of the γ-aminobutyric acid content of rat brain are somewhat higher than this. It thus seems likely that γ-aminobutyric acid may account for much of the Factor I activity found in brain.

The presence of γ-aminobutyric acid in brain was discovered in 1950 by Awapara, Landua, Fuerst and Seale[5], Roberts and Frankel[6], and Udenfriend[7], and it was shown that it is produced from glutamic acid by the action of a decarboxylase[5,6,8] with pyridoxal phosphate as coenzyme[9]. The metabolism of glutamic acid and glutamine and the numerous effects of these substances on metabolic activities, especially in brain, have been reviewed repeatedly. It now appears that a product of glutamic acid metabolism, γ-aminobutyric acid, may play an important part in the control of neurophysiological activity. Recent studies by J. E. Hawkins, jun., and L. H. Sarett, of the Merck Sharpe and Dohme Research Laboratories, on the anticonvulsant activity of substances known to be involved in brain metabolism, have also converged upon γ-aminobutyric acid. This compound is effective in preventing certain types of seizures in mice[10].

Pharmacological studies on the activity of γ-aminobutyric acid are in progress. It may be mentioned that injection of 0·2 mgm. of the substance into the hæmocœl of a 45-gm. crayfish causes the animal to become remarkably flaccid.

Details of this work will be published elsewhere.

We are indebted to Merck and Co., Inc., Rahway, N.J., for aid and co-operation in these studies. One of us (A. B.) is a member of the staff of the Merck Sharpe and Dohme Research Laboratories.

Benzene Hexachloride Metabolism in *Anopheles gambiae*

WE have recently been able to examine the absorption and metabolism of benzene hexachloride by susceptible and γ-BHC-resistant strains of *Anopheles gambiae*. The resistant strain, which originated in an area of northern Nigeria where dieldrin is being used as a residual spray[1], was dispatched to England by members of the Nigerian Malaria Service and has been reared in the laboratories of the Ross Institute, London, by Dr. G. Davidson, who has kindly supplied the insects for our experiments. The resistant strain is some 800 times resistant to dieldrin and 26 times resistant to γ-BHC as determined by Davidson[2] using a modification of the method of Busvine and Nash[3]. The susceptible strain has also been reared in the laboratories of the Ross Institute in London and originated from Lagos, Nigeria.

In order to determine the absorption and metabolism of BHC isomers, deposits of carbon-14-labelled isomers were made from carbon tetrachloride solution in stoppered 100-ml. Ehrlenmeyer flasks and a weighed batch of mosquitoes (50–100 mixed sexes) added. A piece of untreated filter paper was included in the flask to provide a resting place for the insects. After 24 hr. at 25° C., the insects

Table 1. ABSORPTION AND METABOLISM OF α- AND γ-BHC BY *A. gambiae*
(Results expressed as μgm. BHC/gm. insect)

	γ-BHC			α-BHC		
	Susceptible	Resistant		Susceptible	Resistant	
	1	1	2	1	1	2
BHC absorbed	130	132	151	115	138	152
Water-soluble metabolites	14·6	8·0	9·9	14·8	4·8	8·0
Water-soluble metabolites as per cent of BHC absorbed	11	6·1	6·6	13	3·5	5·3

were removed and the radioactive material recovered and estimated as carbon tetrachloride - soluble and water - soluble fractions using techniques already described[3]. Comparative results for the susceptible and resistant strains are summarized in Table 1 for γ-BHC and α-BHC. Experiments with the α-isomer were included because it is known that γ-BHC-resistant flies are able to metabolize this isomer and the γ-isomer with equal facility, whereas experiments with α-BHC have the advantage of allowing a much longer survival of the γ-BHC – susceptible strain with correspondingly increased opportunity for the insects to exhibit their power of metabolizing the compound.

The results show that the resistant strain absorbs no less BHC than the susceptible, and converts a smaller proportion of the absorbed chemical to water-soluble products. (In another set of experiments not reported here, where the absorbed dose of γ-BHC was greater, the susceptible and resistant strains converted approximately equal amounts to water-soluble products.) Isotopic dilution tests with the pure BHC isomers showed that the radioactivity in the carbon tetrachloride extracts was almost all unchanged BHC; carbon tetrachloride - soluble metabolites are therefore not produced in any significant amounts.

In all the experiments with γ-BHC, both strains were knocked down, the susceptible strain after some thirty minutes, the resistant strain after about three hours. A further experiment was therefore carried out in which exposure to the γ-BHC vapour was limited to 1 hr., after which the insects were transferred to a clean flask and stored at 25° C. for 24 hr. before analysis. The results are shown in Table 2.

Although the majority of the mosquitoes were alive at the end of 1 hr. exposure to insecticide and some of the resistant strain were still showing slight movements after 24 hr., the pattern of absorption and metabolism in the short-exposure experiment is very similar to that shown in the 24-hr. exposure experiments. Again the susceptible strain shows a greater percentage conversion of the absorbed γ-BHC to water-soluble products.

The results are published at this preliminary stage to direct attention to the fact that insecticide resistance can be exhibited by a strain of insects which possess no greater power of detoxication of the poison than the susceptible strain. The resistant *A. gambiae* can convert only 11 per cent or less of the absorbed poison to excretable products, the corresponding figures for a strain of resistant houseflies under similar conditions being more than 90 per cent[4]. It seems necessary to look to mechanisms other than detoxication for an explanation of the resistance of these *A. gambiae* to poisoning by γ-BHC.

Table 2. ABSORPTION AND METABOLISM OF γ-BHC BY *A. gambiae*.
(Results expressed as μgm. BHC/gm. insect)

	Susceptible	Resistant	
	1	1	2
Outside (CCl$_4$-soluble)	2·8	2·0	3·6
Inside (CCl$_4$-soluble)	12·5	15·1	10·7
Water-soluble	2·8	2·0	1·2
Residue	0·0	0·0	0·0
Storage flask (CCl$_4$-soluble)	8·3	4·0	3·6
Total	26·4	23·1	19·1
Per cent metabolized	11	9	6

We thank Dr. G. Davidson for his collaboration and help in these experiments.

A Simple Method for the Investigation of Peptides containing Cystine and/or Cysteine

THE lability of sulphur-containing peptides makes their identification in tissues and fluids a peculiarly difficult problem. The simple procedure described here makes use of the fact that, while cysteine and cystine are held by a cation-exchange resin, cysteic acid is not. By transferring the cationic substances of a fluid to a cation exchange resin, washing it, and treating it with hydrogen peroxide, cysteine, cystine and peptides containing these residues are preferentially released into the supernatant fluid. Recovery of cysteine, cystine and homocystine was 77 per cent and of glutathione 25 per cent calculated from spectrophotometric estimation as their dinitrophenyl derivatives at 352 mμ. Methionine forms a sulphone which remains attached to the resin. Cysteic acid and oxidized glutathione could be separated by displacement chromatography from an anion exchange resin with $N/10$ hydrochloric acid. A simpler procedure utilized transfer of the oxidation products to a small amount of an anion exchange resin to remove them from the large excess of hydrogen peroxide, followed by displacement with hydrochloric acid and paper ionophoresis. The following examination of blood is typical.

The dialysate from 5 ml. of clotted human blood was mixed for one minute with the sulphonated polystyrene resin 'Amberlite' *IR* 120 (H) (2 gm.). Washing was performed by topping up the tube with distilled water, mixing, allowing the resin particles to settle, and sucking off the supernatant fluid. Sufficient 100 volumes hydrogen peroxide to cover the resin was added. After 6–18 hr. at 22° the supernatant fluid was washed through a filter paper into 'Amberlite' *IRA* 400 acetate (0·1 gm.), and mixed with it for one minute. After washing with water, 3 N hydrochloric acid (0·1 ml.) was added, and after one minute the supernatant fluid was taken to dryness at 22°. The residue was transferred to Whatman No. 31 paper and subjected to ionophoresis in $M/10$ diethylamine – acetic acid buffer pH 3·6 containing 5 per cent glycerol[1] in the apparatus of Flynn and de Mayo[2] at a potential difference of 200 volts for

3 hr. After drying the paper in a current of air, spraying with ninhydrin and heating, two spots, corresponding to cysteic acid and oxidized glutathione, appeared. The presence of glutathione in potato extracts was similarly demonstrated. Urine extracts contained substances which caused gross distortion of the ionogram. Considerable improvement was obtained by preliminary chromatography in butanol–acetic acid, the material running at the same rate as that giving a positive ninhydrin reaction on a marker strip being eluted and run ionophoretically. A strong cysteic spot and a weak spot moving at the same rate as oxidized glutathione was then detectable. Hydrolysates of blood and potato extract preparations contained only cysteic acid, glycine and glutamic acid; urine extracts contained, in addition, α-alanine and aspartic acid.

Cleavage of N-Glycosidic Linkage in Peptide-ε-lysyl-N-glycosides by Ion Exchange Resin

It is well known that the sugar components of amino-acid-glycosides are not always detected in the acidic hydrolysates; this is in accordance with the general characteristics for the Amadori rearrangement[1]. However, there have been difficulties in elucidating the detailed structure of an amino-acid-glycoside which includes an oligosaccharide.

Recently, Finan and O'Colla have reported a method for the stepwise degradation of the glycosidic linkage in disaccharide osazones with the cation exchanger 'Zeo-Karb' 215 at room temperature[2]. This method has now been developed for the selective cleavage of the N-glycosidic linkage in ε-lysyl-N-glycoside without decomposition of the sugar components. The principle of this method is based on the observation that the anion resin 'Amberlite' *IRA*-410 hydrolysed the N-glycosidic linkage in peptide-ε-lysyl-N-glycosides, lactoside and lactuloside separated from the tryptic hydrolysates of milk products[3,4]; but the disaccharide remained unchanged under the same conditions.

A typical procedure is as follows: a column (10 cm. × 0·7 cm.) of 'Amberlite' *IRA*-410 (OH^- form) was washed with water and then 15 mgm. of the material dissolved in 1 ml. of water was placed on the column and left in contact with the resin for 10 min. The column was eluted with 1 per cent sodium hydroxide and passed through a column of 'Amberlite' *IR*-4*B* (H^+ form) in order to remove sodium. The neutralized elute was lyophilized to a syrup, which was shown by paper chromatography to contain disaccharide, lactose or lactulose and aglycone-peptide. The fact that the N-terminal-ε-amino group of lysine in the peptide was released by this treatment was also confirmed by means of the dinitrophenol method of Sanger and Tuppy[5].

On the other hand, somewhat similar experiments using 'Amberlite' *IR*-120 (H^+ form) as the absorbent and 1 per cent acetic acid as the eluting agent were not successful, since it was found that the lactoside remained and the lactuloside was split into several fractions. In addition, α-amino-acid-N-glycosides, namely, glycine-, alanine- and phenylalanine-fructoside prepared by the method of Abrams *et al.*[6], were also treated similarly with 'Amberlite' *IRA*-410. The results obtained, however, eliminated the possibility of degradation of N-glycosidic linkage in them.

On the basis of these results, it is accordingly suggested that the N-glycosidic linkage in peptide-ε-lysyl-N-glycosides are degraded selectively by 'Amberlite' *IRA*-410. This method was applied to the determination of the fine structure in the amino-acid-glycosides formed secondarily in the milk protein–lactose system[7]. Hence these results have perhaps a bearing on the nature and structure of amino-acid-N-glycosides formed in the protein–sugar complex and protein foods as the first intermediate in the amino-carbonyl (or Maillard) reaction of these systems. It is possible that further investigations, which are proceeding, will show that this result can be further generalized.

I wish to thank Profs. R. Sasaki and T. Nakanishi for their guidance; thanks are also due to Dr. K. Shibasaki for valuable suggestions.

Genetic and Hæmatological Significance of Hæmoglobin H

Late in 1954, I discovered two adult Filipino men unrelated to each other with a thalassæmia-like blood picture. Electrophoretic examination of hæmoglobin at *p*H 8·6 and 6·0 revealed a major component of normal hæmoglobin and a minor component with electrophoretic mobility faster than normal hæmoglobin A; further work led to identification of the new fraction as hæmoglobin H. Detailed studies on these patients will be published elsewhere.

Family studies on the inheritance of hæmoglobin H in a Chinese[1] and a large Greek[2] family as well as in a number of Thai[3] kindreds failed to demonstrate the abnormal pigment in the parents of the index cases with hæmoglobin H. Genetical investigations of these families revealed that one of the parents and several other members of the family had the thalassæmia trait without hæmoglobin H. The hæmatological findings of all cases with hæmoglobin H hitherto studied suggested the additional presence of thalassæmia. It may therefore be postulated that hæmoglobin H is only shown electrophoretically in the presence of thalassæmia. In this respect hæmoglobin H differs from most of the other human hæmoglobins such as A, C and S (and probably D, E, G and I) which are easily detectable in the trait or carrier state and the production of which presumably is under the control of multiple alleles. The finding of hæmoglobin H in thalassæmia has certain resemblances to the behaviour of hæmoglobin F, which is sometimes found in the thalassæmia trait and is not inherited quantitatively.

Since my two original patients were Filipinos, I recently examined the hæmolysates of seventy-three Filipino sailors (through the kind co-operation of Dr. E. H. Giblett, King County Central Blood Bank, Seattle, Washington) and three Filipino patients with non-hæmatological disease by paper electrophoresis at pH 8·6 (barbital buffer) and pH 5·8 (phosphate buffer), it having been found that hæmoglobin H could be best demonstrated at acid pH. No example of hæmoglobin H or any other electrophoretically demonstrable abnormal hæmoglobin was found. The absence of hæmoglobin H carriers in this limited population known to be a possible reservoir for hæmoglobin H provides further suggestive evidence that the trait for hæmoglobin H may not exist, or else has poor penetrance with the presently used methods of electrophoresis. The presence of pure thalassæmia trait without hæmoglobin H in siblings of patients with 'thalassæmia–hæmoglobin H disease' supports the latter hypothesis. Multiple allelism between thalassæmia and hæmoglobin H appears to be excluded since the combination of hæmoglobin H and thalassæmia has been reported[2] in the son of a patient with 'thalassæmia–hæmoglobin H disease'. Further surveys among Filipinos, Chinese, Greeks and related races need to be performed. In the present state of our knowledge, the demonstration of hæmoglobin H apparently signifies the simultaneous presence of thalassæmia. 'Thalassæmia–hæmoglobin H disease' therefore may be considered a variant of thalassæmia in which the thalassæmia gene in a yet unknown manner activates the expression of hæmoglobin H.

This investigation was supported by State of Washington Initiative 171 funds for research in biology and medicine and by an American Cancer Society Institutional grant.

Postnatal Formation of Hæmoglobin E

IN order to find out whether hæmoglobin E is formed during fœtal life or some time after birth, the following investigation was carried out.

A survey for pathological hæmoglobin was carried out among women who were about to give birth to a child in the delivery room of the Department of Obstetrics of the Central General Hospital in Djakarta. The blood of babies of mothers carrying hæmoglobin E in their blood was examined at birth and at varying intervals after birth up to the age of three to five months. Among two hundred pregnant women, nine were found to be carriers of the hæmoglobin E trait, having hæmoglobin E in their blood in addition to the normal hæmoglobin A. Eight babies of mothers carrying hæmoglobin E in their blood were examined. At birth none of them showed hæmoglobin E in their blood on paper electrophoresis. Five of those babies could be followed up. Three who were examined at intervals up to the age of three to five months did not show hæmoglobin E in their blood when examined by paper electrophoresis. In the two other babies, hæmoglobin E was detected some time after birth. In one it was found when the baby was four months old while the fœtal hæmoglobin was 28·7 per cent of the total amount of hæmoglobin. At birth and at the age of 1½ months no hæmoglobin E could be detected in this baby by paper electrophoresis. At the age of 5½ months the amount of hæmoglobin E had increased while the amount of fœtal hæmoglobin had decreased to 10·3 per cent of the total amount of hæmoglobin.

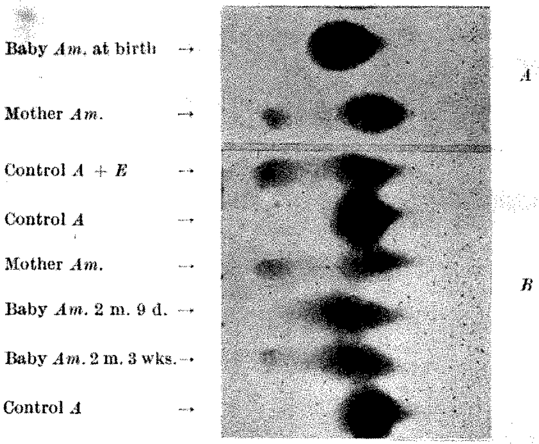

Fig. 1. Paper electrophoresis, pH 8·6, showing the postnatal formation of hæmoglobin E. (*A*) At birth no pathological hæmoglobin was found in the baby. (*B*) At the age of 2 months and 9 days a pathological hæmoglobin in a very low concentration with a mobility higher than that of hæmoglobin E was found, while at the age of 2 months and 3 weeks hæmoglobin E was clearly present in the blood

In the other baby no hæmoglobin E was found at birth, and the fœtal hæmoglobin was 80·1 per cent of the total hæmoglobin. At the age of 2 months and 9 days, however, a small amount of pathological hæmoglobin was found, which showed a mobility greater than that of hæmoglobin E. Since the father of the child was entirely normal, no pathological hæmoglobin other than hæmoglobin E was expected. Therefore the difference in mobility may be assumed to be caused by the very low concentration of hæmoglobin E found in the baby. However, the possibility of a transitional form of hæmoglobin E being formed at an early age could not be ruled out. This interesting point needs further investigation. At the age of 2 months and 3 weeks, the presence of hæmoglobin E in the baby was beyond doubt (see Fig. 1).

In these two babies, therefore, hæmoglobin E was formed some time after birth.

This investigation is the subject of part of a thesis written in Indonesian (May 1956). While the work was being carried out, a paper by Schneider and Haggard appeared[1] reporting the delayed formation of hæmoglobin S in several babies examined and the delayed formation of hæmoglobin C in one baby. Also, Thomas, Motulsky and Walters[2] have reported the postnatal formation of hæmoglobin C in one case examined.

Multiple Hæmoglobins in the Blood of Animals

In the course of our investigations on the hæmoglobins in the blood of various animal species by the agar electrophoresis technique[1,2], it was found that the blood of buffalo contained two distinct hæmoglobins. Blood hæmolysates were prepared by the method of Drabkin[3] without using aluminium chloride. The hæmolysate was applied on the surface of the agar gel (0·5 per cent) containing 0·05 ionic strength barbital buffer of pH 8·6. Electrophoresis was carried out according to the procedure described before[4]. After electrophoresis (200 V., 6 m.amp., 6 hr.) the hæmoglobin bands could be observed visually. Under ultra-violet light using Wood's filter the bands could be seen more clearly. The hæmoglobin bands could be stained with amido black 10B after drying the agar plate and the concentrations of the components could be determined densitometrically. The region occupied by the hæmoglobins shows positive reaction with benzidine reagent. Rat blood hæmolysates showed the presence of two minor components of proteins in addition to the major component of hæmoglobin.

Typical hæmoglobin patterns of buffalo and rat, together with the normal human serum protein pattern obtained on the same agar plate for comparing the mobilities, are shown in Fig. 1. The mobility of the hæmoglobin of the rat blood haemolysate corresponds to that of β-globulin of human serum, while the other two minor components have approximately the same mobility as γ-globulin. Haurowitz *et al.*[5], in their study on the alkali denaturation of hæmoglobins, have suggested the presence of two or more components of hæmoglobins in rat blood as indicated by a break in the alkali-denaturation velocity curves. The identity or otherwise of these two minor components with hæmoglobin is being investigated further. The slow-moving component of hæmoglobin in buffalo blood has the mobility of β-globulin, and the fast-moving major component has a mobility higher than that of β-globulin. The blood of other animals investigated, namely, cow, sheep, goat, horse, dog, rabbit and guinea pig, contains only one hæmoglobin under the conditions of electrophoresis described, namely, at pH 8·6 and 0·05 ionic strength of barbital buffer. Harris and Warren[6] have, however, reported the occurrence of two hæmoglobins in the blood of some sheep examined by them.

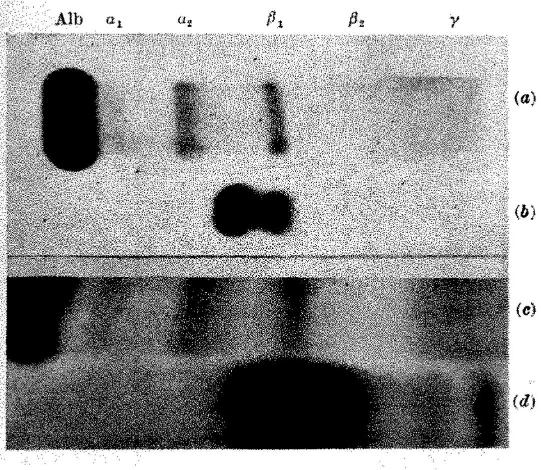

Fig. 1. Agar electrophoresis patterns of blood hæmolysates of buffalo and rat compared with the pattern of normal human serum proteins
a, normal human serum; *b*, buffalo blood hæmolysate; *c*, normal human serum; rat blood hæmolysate

Further characterization, isolation and amino-acid composition of the buffalo blood hæmoglobins are being studied. Investigations on the hæmoglobins of other animal species are in progress.

Occurrence of *trans*-Unsaturated Fatty Acids in Horse Fæces

It has been shown recently[1,2] that whereas the depot fats of ruminants contain considerable amounts of *trans*-unsaturated acids (3·5–11·2 per cent) the depot fats of non-ruminants contain but little or none. Since the rumen bacteria exhibit a pronounced hydrogenating effect[3] and hydrogenation induces *trans*-isomerization, the occurrence of *trans*-acids in the fats of ruminants has been attributed by us to bacterial action[1,2]. This hypothesis has now found additional support from the determination of the *trans*-acids content of horse fæces from pasture-fed animals. The lipids isolated from fresh fæces (6·66 per cent on the moisture-free basis) contained approximately 14 per cent of these acids determined by the infra-red absorption technique[4] (Table 1), whereas no *trans*-acids could be detected in the depot fat of pasture-fed horses[1,2]. In view of the fermentative bacterial flora in the large intestines, and the reducing atmosphere in these organs, the above result is not unexpected, and points to a mechanism of *trans*-acids formation similar to that in the rumen, but occurring in the post-absorptive region of the gut. The iodine value and the diene and triene contents of the fatty acids from the fæces, shown in Table 1, indicate also extensive hydrogenation when compared with the corresponding data for the depot fat of the horse[5], and for pasture lipids[6].

On the other hand it is surprising that the carotene contents of the fæces (0·12 per cent of dry matter) was much greater than that of the pasture (0·05 per cent)[7], this being accompanied by a reversal in the ratio between carotene and xanthophyll, namely, 4 : 1 in the fæces against 1 : 2 in the pasture[8].

Table 1. CHARACTERISTICS OF FATTY ACIDS FROM HORSE FÆCES, HORSE DEPOT FAT AND PASTURE

Source	Iodine value	% Conjugated		% Unconjugated		% *trans*-acids
		diene	triene	diene	triene	
Horse fæces	37·8	1·2	nil	0·7	0·9	14·1
Horse depot fat	96·4	0·5	trace	3·3	16·1	Not detected
Rye-grass (*Lolium perenne*)	183·0	0·9	0·1	10·7	62·7	trace

The investigation of the *trans*-acids content of the fæces of various ruminants and non-ruminants is in progress.

Influence of Nutrition upon Duration of Gestation in Sheep

Various effects of different planes of nutrition on pregnancy in the ewe have been studied; but there appears to be no record of an effect on duration of gestation. Four series[1] of observations were made, in which Merino ewes were maintained on high, medium and low planes of nutrition from the 108th, 129th, 136th or 143rd day of pregnancy to parturition. The distribution of the treatments among the four series is shown in Table 1. Prior to the experimental nutritional period, ewes had either been maintaining or gaining weight. During the experimental period, the ewes on the low plane in series 4 and 6 received chaffed wheaten hay only. All other ewes received a mixture of equal parts of oats and chaffed legume hay, with or without pasture. Ewes on the high plane of nutrition in each instance were allowed access to food *ad lib.* and gained about 0·2–0·4 kgm. in weight per head per day. In each series the ewes on the low plane of nutrition received about 0·2 kgm. (dry weight) of food per day each and lost about 0·2–0·4 kgm. in weight per day. Ewes on the medium plane received sufficient food to maintain constant body-weight.

All ewes in series 4, 5 and 7 bore single lambs. Some ewes in series 6 bore twins.

The mean duration of gestation in each group is set out in Table 1, together with the standard error of the mean, the number of ewes involved and the significance of differences. In each series, the mean duration of gestation of each group of low-plane ewes was less than that of each comparable group of high-plane ewes by amounts which ranged from 0·7 to 5·0 days. Most of these differences were statistically significant. In series 5, in which groups of ewes were subjected to a low plane of nutrition after the 108th or 129th day of pregnancy respectively, the mean duration of gestation was significantly the shorter by 2·3 days in the ewes in which the period of treatment was the shorter. The difference of 2·5 days was in the reverse direction in series 4, where ewes were subjected to a low plane of nutrition during the much shorter periods from the 136th and 143rd day of pregnancy to term.

A record was available of ewes which developed clinical signs of pregnancy toxæmia in series 7 the difference between means was still significant when ewes showing these symptoms were eliminated

Although attention has not been directed by other workers to an effect of undernutrition upon duration of gestation, the data which Thomson and Thomson present support the present findings. In their data concerning ewes maintained on high and low planes of nutrition during the second half of pregnancy, the mean duration of gestation of the low-plane ewes which bore twins, 146·5 days, was significantly shorter ($P = 0·05$) than that of the corresponding high plane ewes, 149·0 days; in ewes bearing single lambs the respective means of 148·4 and 149·0 days differed in the same direction but the difference was no significant. These data clearly demonstrate tha severe undernutrition may affect duration of gesta tion; but the lack of consistency between the results of series 4 and 6 indicates that the magnitude of the effect may vary in various circumstances.

The available data also suggest that in a group o comparable ewes the heavier the uterine contents are at the time treatment is commenced, the more is parturition advanced by undernutrition, provided treatment is not commenced within a few days o parturition. Thus it was more advanced among twins than among singles and among older fœtuses

Table 1. Mean Duration of Gestation of Ewes on Different Planes of Nutrition

Series	Group	Nutritional treatment		No. of ewes	Duration of gestation (days)			Significance of differences between means‡†

than among younger ones except where underfeeding was commenced close to term. This suggestion supports the hypothesis which was advanced as early as 1891 by Spiegelberg[3] that insufficiency of fœtal nutrition is a factor concerned in the initiation of parturition. Certainly the fœtus or fœtal placenta must be concerned in this process, as a sire influence on length of gestation in sheep has been demonstrated by Terrill and Hazel[4]. This suggestion and Spiegelberg's hypothesis provide a basis for an obvious explanation of the findings, reviewed by these workers, that gestation in ewes bearing twins is usually shorter than in ewes bearing singles.

The present results add another item to the list of those which must be explained by any hypothesis about the factor or factors which actually precipitate parturition.

Visual Pigments of Deep-Sea Fish

Experiments have been made on board R.V. *Sarsia* with the fresh retinæ of four species of deep-sea fish caught in the Bay of Biscay. These species, *Stomias boa* (Risso), *Flagellostomias* sp., *Argyropelecus olfersii* (Cuvier) and *Myctophum punctatum* Rafinesque, are often caught around 500 m.[1], a depth close to that at which the human eye ceases to see the light of day[2].

Simple visual inspection showed that the unbleached retinæ were golden coloured. Fig. 1 demonstrates that the changes in spectral absorption on bleaching such retinæ were those of retinal photosensitive pigments differing from visual purple in having their maxima displaced about 20 mμ toward the blue end of the spectrum. The retina of the conger eel has recently been shown to contain a pigment with an absorption curve very similar to those described here[3,4] (Fig. 1). The conger begins life in the deep ocean and returns there when mature.

The golden-coloured pigments which were found in high density in all these retinæ are admirably suited to make the best use of that fraction of daylight which penetrates deep into oceanic waters. These waters are most transparent to blue light around 475 mμ [5], and at depth this is effectively the only light.

Wald[6] has made the generalization that the retinæ of fresh-water fish contain purple pigments (porphyropsins) and those of coastal marine fish contain rose pigments (rhodopsins). We may now add another group, those of deep-sea fish the retinæ of which have principally golden-coloured pigments for which we suggest the name chrysopsins or visual golds.

We are grateful to Mr. N. B. Marshall of the British Museum (Natural History) for identifying the deep-sea fish and to Captain C. A. Hoodless and the crew of the Marine Biological Association's research vessel *Sarsia* for their enthusiastic co-operation.

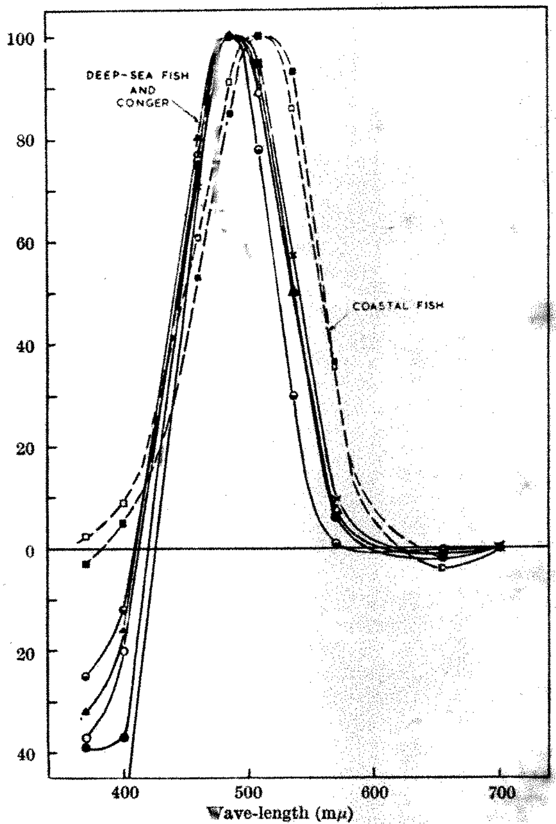

Fig. 1. The curves are of spectral density change of fresh retinæ when bleached with white light. Four deep-sea fish : ×, *Stomias boa* (Risso) ; ●, *Flagellostomias* sp. ; ◒, *Argyropelecus olfersii* (Cuvier) ; ▲, *Myctophum punctatum* Rafinesque. A migrating fish : ○, *Conger vulgaris*. Two coastal fish : □, *Scophthalmus rhombus* ; ■, *Cottus bubalis*. The ordinate is change in density (expressed as a percentage) ; the maximum density change is made equal to 100 per cent

The kindness of the Director of the National Institute of Oceanography has enabled the results described here to be confirmed and extended by experiments made aboard R.R.S. *Discovery II*. Fifteen species of deep-sea fish were found to have golden-coloured retinal photosensitive pigments and only one oceanic fish, a surface form, *Saurus scombresox*, to have visual purple.

Sex Determination in Rats (*Rattus norvegicus* var. *albinus*) through the Ameloblasts of the Dental Germ

Since 1949, Barr *et al.* and others[1-3] have described the presence of 'sex chromatin' in various tissues of several animal species, arriving at the conclusion that in all of them behaviour of this 'sex chromatin' was practically identical. They excluded, however, certain rodents and lagomorphs, since it was impossible to determine their sex from nuclei of the tissues studied.

The importance of these studies became apparent when Barr[4] and Decourt *et al.*[5] applied these concepts to the determination of sex in human pathology.

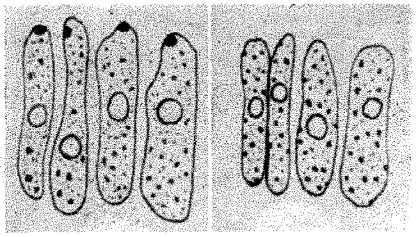

Fig. 1. (a) Nuclei in the adamantine epithelium of a female rat. They contain the 'sex chromatin' at the pole of the nucleus nearer to the growing enamel (Feulgen); (b) nuclei in the adamantine epithelium of a male rat, where no 'sex chromatin' is found (Feulgen)

Barr admitted that 'sex chromatin' consisted of the heterochromatic portions of the sex chromosomes. A new hypothesis[3], based on the studies of Pavan and Breuer[6,7], was suggested to explain the morphophysiological behaviour of the chromosomes of *Rhynchosciara angelae*.

With the view of extending the application of this method of sex determination to other fields, we decided to study the 'sex chromatin' of the ameloblasts in the dental germs of one-day old albino rats.

Ten females and ten males were used. The heads were fixed in 10 per cent formalin buffered to *p*H 6·9. Frozen frontal sections, 15–20μ thick, were obtained at the level of the first molars. After prolonged and repeated washing in distilled water, they were stained by Feulgen's technique.

The sex of the rats was previously determined by the examination of the ano-genital distance.

From each head, five sections were studied. In each section, one hundred ameloblasts were studied, that is, five hundred cells per animal.

In 89·8–91 per cent of the nuclei of the ameloblasts from the females, a chromatin mass was found, almost always on the side of the growing enamel, adhering to the nuclear membrane and having on the average a diameter of 1μ (Fig. 1*a*).

A similar mass, though smaller, was found in the ameloblasts from the males, in 6·8–18 per cent of the cases (Fig. 1*b*).

The ameloblasts present a special 'chromatic pattern', differing from that of other tissues, in which the 'sex chromatin' is not easily distinguished from the other chromatin masses; this, as Barr points out, makes it difficult to determine the sex.

One of us, however, after a great many counts of the chromatin masses found in the cells examined, and based on the distribution of the various 'chromatin patterns', arrived at the conclusion that sex determination in these animals is quite possible.

At present, we are studying the determination of the sex by the examination of the ameloblasts in other animal species.

α- and γ-Lysin Production by *R* Variants of *Staphylococcus aureus*

IT was shown[1] that *R* variants of *Staphylococcus aureus* differ from *S* in producing more coagulase; this led to an investigation of other biological properties of the two variants.

The present communication concerns the production of α- and γ-lysin of the variants. β-Lysin was studied only qualitatively and δ-lysin not at all.

Ten coagulase-positive strains of human and animal origin were used: all were laboratory strains kept on artificial media for periods of upwards of one year; they differed quantitatively in production of α-lysin: four of the ten produced β-lysin. The strains included the well-known coagulaes-producing strain Newman (Duthie), two α-producing strains *C* 13 and *C* 16 (Elek) and strain 5664 (N.C.T.C.) the strain on which γ-lysin was originally described by Smith and Price[2].

Whereas one strain showed the presence of *R* variants on isolation and strains 5664 and 3917 (Burroughs Wellcome) gave an almost pure growth of *R* colonies on direct plating of the stock cultures, *R* variants of the remaining seven strains were obtained only by plating old broth cultures on chocolate agar[1]. The morphology of the colonies ranged from irregularity in outline to frank roughness. The rough character of the colonies was emphasized by growth on agar containing 0·5 per cent 'Dispersol *L-N*' (Imperial Chemical Industries, Ltd.).

The hæmolysins were prepared from *R* and *S* variants by Burnet's method[3], that is, by incubation on semi-solid media in a mixture of carbon dioxide and air; high yields of α- and γ-lysin were obtained in 24 hr.

Since both α- and γ-lysins are estimated by lysis of rabbit red blood cells, difficulty is often experienced in determining the presence and titre of one of the lysins when both are present. The difficulty was circumvented by using pure anti-γ and anti-α sera respectively. The anti-γ serum was obtained by immunization of a rabbit with the lysin of an *R* variant (5*R*) known to produce γ-lysin to a high titre and only traces of α-lysin; at the dilutions at which this serum was used only anti-γ was present. The anti-α serum was obtained by removing from an anti-α and anti-γ serum the anti-γ fraction by flocculation; the method is a slight modification of the one suggested by Marks[4].

It was found that all *R* variants were poor α-lysin producers; the α-lysin titres, expressed as the reciprocals of the highest dilutions of culture fluids showing lysis, ranged from traces to a maximum of 500: their γ-lysin titre was relatively high and ranged from 256 to 1,000. The *S* variants encountered fell into two types: one hæmolytically inactive, the other one producing the same amount of γ-lysin as the *R* variants but with higher α-lysin titres (ranging from 500 to 16,000). It was noticed that in the strains examined β-lysin was produced by both *S* and *R* variants or by neither.

If conclusions are permissible from the limited number of strains studied, *R* variants appear to be characterized by total or partial loss of α-lysin production without loss of γ-lysin. It also appears that *R* variants of suitable strains may in future be used in order to obtain good yields of γ-lysin free of α- and β-lysins.

I wish to thank Dr. E. S. Duthie and Dr. S. D. Elek for strains, Dr. Francis and Miss Mollie Barr of the Burroughs Wellcome Research Laboratories for strains and antisera, and Dr. J. Marks for antisera.

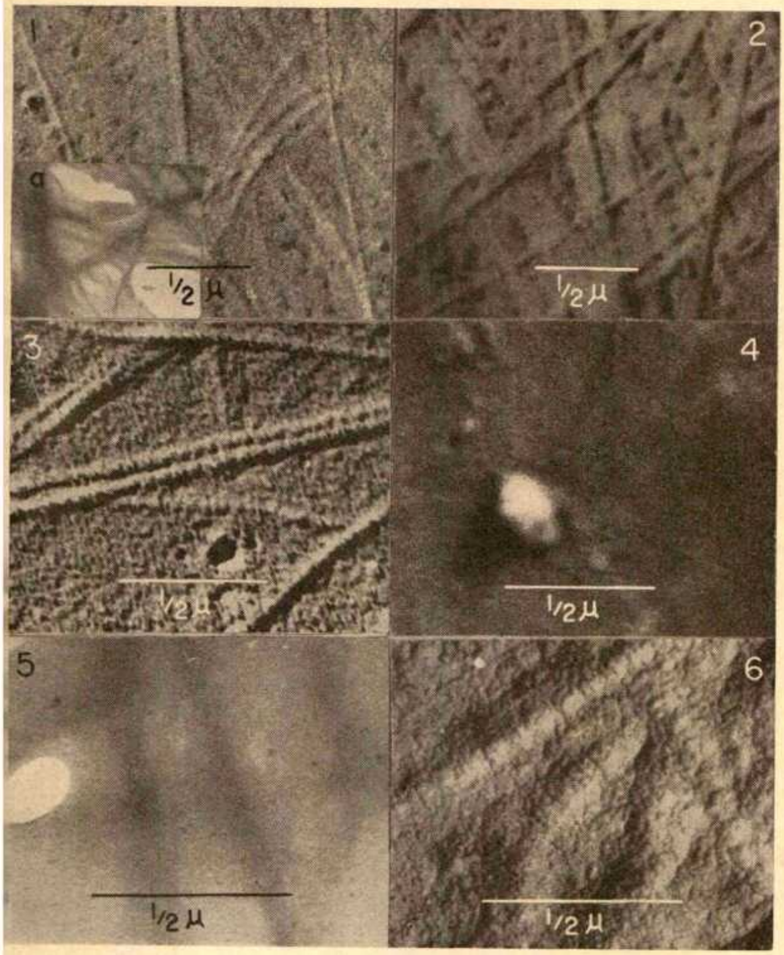
An Electron Microscopic Study of the Ground Substance of Connective Tissue

GROUND substance has been studied by histochemical, physiological and pharmacological methods. This communication reports some electron microscopic observations made on experimentally induced changes in ground substance. A technique is described for the study of ground substance with the electron microscope.

Cuticles of subcutaneous loose connective tissue of treated and untreated mice are spread on electrolytic copper specimen screens, air-dried, shadowed with uranium, and observed with an *RCA* electron microscope (Model *EMU* in accordance with standard procedures[1]. No artificial supporting membranes, enzymes or chemicals are used.

Animals employed in these experiments are *CBA* mice 12–16 weeks old, grouped as follows: (1) untreated control; (2) adrenalectomized; (3) stressed by excitement or starvation; (4) locally inflamed by mechanical irritation 2 hr. prior to killing; (5) injected subcutaneously with (*a*) 0·25 mgm. hydrocortisone 12 hr. before killing, (*b*) 0·25 mgm. deoxycorticosterone 12 hr. before killing, (*c*) 60γ heparin 30 hr. before killing, or (*d*) 35 T.R. units of hyaluronidase 3 hr. before killing.

The controls used are untreated intact *CBA* mice, the connective tissue of which is removed in the same manner as in the experimental groups, described above. The time intervals selected for observation of changes following treatment are the same as those successfully used in studies of inflammatory response, as well as other histochemical studies carried out in this laboratory.



Electron micrographs of intercellular elements of subcutaneous connective tissue of mice. All are shadowed with uranium except Fig. 1*a*, which is non-shadowed.

(1) Untreated control. ×27,000. (1*a*) Same as Fig. 1, but non-shadowed. (2) Treated locally with heparin. ×27,000. (3) Treated locally with hydrocortisone. ×40,000 (similar to that of intact stressed group). (4) Treated locally with deoxycorticosterone. ×40,000 (similar to that treated with hyaluronidase). (5) Adrenalectomized for 24 hr. ×40,000. (6) Stressed for 30 min. ×60,000

Shadowing with uranium reveals the surface morphology of ground substance, though in most cases it obscures the finer fibrillar network (Figs. 1, 1*a*). In the untreated controls the shadowed ground substance appears finely granular. The ground substance of the intact stressed (but not adrenalectomized) animals, and of those treated with hydrocortisone, is strikingly tufted and granular in appearance (Figs. 3 and 6). This tufted character is attributed to evenly distributed, uniform granules about 100 A. in diameter. Marked similarity is observed in the appearance of the ground substance in the groups treated with hyaluronidase or deoxycorticosterone and in the adrenalectomized or locally inflamed groups (Figs. 4 and 5). In these four groups the ground substance appears smooth, agranular, and homogeneous, whereas treatment with heparin increases the fibrous elements (Fig. 2).

In the groups treated with corticosteroids, irregularly shaped particles or crystalloids having diameters of 4,000 A. or less are observed in or on the matrix of the ground substance (Fig. 4).

It has been reported that cortisone and adrenocorticotropic hormones cause a decrease in the permeability of ground substance, while adrenalectomy, deoxycorticosterone and hyaluronidase induce an increase in permeability[2].

The hypothesis that changes in the physical and physiological behaviour of ground substance result from changes in its degree of polymerization[3] may be utilized to explain the morphological alterations shown here. Since hyaluronidase, deoxycorticosterone and adrenalectomy cause a marked increase in the permeability of ground substance and produce a strikingly similar morphological appearance, it is assumed that this appearance is that of 'depolymerized' ground substance. By comparison, the tufted appearance of ground substance produced by hydrocortisone treatment is apparently due to an increase in its degree of polymerization.

The morphological alterations in the surface of the ground substance may be explained on the basis of the resolving power of the electron microscope, which is, at best, about 10 A. Highly 'polymerized' components of ground substance consist of macromolecules, resolvable by the electron microscope, which give to the ground substance its characteristic granular appearance. In the 'depolymerized' state, on the other hand, the ground substance appears smooth and agranular because presumably it is composed of smaller molecules or structures which cannot be resolved by the electron microscope.

The increase in fibrous elements induced by heparin treatment may be explained by the possible influence of this drug on the precipitation of 'procollagen', which is reported to exist in soluble form in the intercellular matrix of connective tissue.

A detailed report of this work, which was supported by the United States Department of the Army Grant No. *DA*-49-007-*MD*-130, and a grant from the Armour Laboratories, is in preparation for publication elsewhere.

Koch's Postulates applied to the Micro-ecology of Fungi inhabiting Root Surfaces

While Koch's postulates have frequently been applied for the demonstration of the pathogenic status of a fungus attacking plant organs, so far as we are aware these postulates have not been applied to the solution of problems of the micro-ecology of root-surface inhabiting fungi. This communication is presented in the hope that the method may be of interest to workers in the field of rhizosphere studies.

Investigations carried out in this Department of the incidence of fungi inhabiting the root-surfaces of numerous plants, employing the washing technique of Harley and Waid[1], have shown that sterile mycelial hyphæ of species of *Pythium* and of *Rhizoctonia solani* grow out from the surfaces of washed roots within the first 18–36 hr. of incubation at 25° C. Such fungi are considered to grow over the root surfaces. It was decided to examine the degree to which a strain of *Rhizoctonia solani* isolated from washed roots of *Taraxacum officinale* would colonize the root surfaces of a series of plants and could be recovered from such root systems.

An inoculum was prepared by allowing sterile, single cotyledons of garden pea to become thoroughly infected by incubating the cotyledons on actively growing cultures of the strain of *Rhizoctonia*. Air-dried soil, screened to pass a $\frac{1}{4}$-in. sieve, was adjusted to a water-holding capacity of 60 per cent, packed into glass tumblers, covered with 'Cellophane', and steamed for 45 min. It was allowed to stand for one week before inoculation and transplantation of the test seedlings. Such steaming reduces the soil microflora without effecting complete sterilization. Seedlings of lettuce, onion, pea, tomato, barley and oat were grown from seed and grain, surface-sterilized for one hour in calcium hypochlorite solution, washed in sterile water and incubated at 25° C. Three seedlings of each species were transferred to each tumbler of steamed soil and for each species three tumblers were inoculated with infected pea cotyledons and two were kept as uninoculated controls. During the subsequent three weeks of incubation the water content of tumblers was maintained by periodic addition of sterile tap water.

On harvesting, the roots of each group of seedlings were shaken free of loosely attached soil, vigorously washed in three changes of sterile tap water and transferred to a sterile Petri dish. Five pieces of root each 1 cm. long were selected at random from each group and plated on plain water agar. Table 1 sets out the degree of recovery, after 22 hr. incubation at 25° C., of *Rhizoctonia* in one set of experiments. Mycelium was recovered from some of the root pieces of the control plants but did not belong to *Rhizoctonia*. Repetition of these experiments gave entirely comparable results.

Table 1. Recovery of *Rhizoctonia solani* from Root Systems growing in Inoculated Soil

Root pieces	Species					
	Barley	Lettuce	Oat	Onion	Pea	Tomato
1	1	2	3	2	0	4
2	2	2	3	1	0	3
3	2	1	4	3	2	4
4	0	0	4	0	1	2
5	2	2	4	0	0	3

Figures represent the abundance of hyphæ growing from each root piece, 4 being the maximum score.

Since the experimental soil had been steamed and not sterilized, colonization of root systems was effected against a certain degree of competition but against much less than would have been the case in normal field soil. The results demonstrate that a fungus repeatedly isolated from the surfaces of thoroughly cleansed roots can be recovered from the root surfaces of seedlings growing in soil inoculated with that species under conditions of minimal competition from normal soil saprophytes. They also indicate that fungi, isolated from root surfaces when introduced into soil with a reduced microflora, find their ecological niche on the surface of root systems growing through such soil. In these experiments there was no evidence of preferential selection of root surfaces in relation to the higher plant species by the particular strain of *Rhizoctonia solani*. Inasmuch as this fungus has been repeatedly isolated from washed root surfaces, has been inoculated into steamed soil in which seedling roots have been growing, and has been recovered from vigorously washed root surfaces of a series of root systems, the experiments described represent an application of Koch's postulates to the micro-ecology of the fungal flora of root surfaces.

Root Exudates of Paddy

THE importance of studying root exudates in understanding the behaviour of the rhizosphere microflora is now well recognized. Many techniques have been evolved for collecting root exudates under non-sterile conditions without regard to the attendant injury to root system and with the consequent sloughing off of the root cortex[1]. This communication records an attempt to overcome these defects in technique by collecting the exudates under sterile conditions, during the first week of the growth of the plants.

Two strains of paddy, one resistant (*GEB*.24) and the other susceptible (*MTU*.9) to the 'foot-rot' disease caused by *Fusarium moniliforme* were used as test plants. Two superimposed filter papers (Whatman No. 1) of approximately 8 cm. diameter were placed in 'Pyrex' flasks, moistened with 1/10 *N* Richard's solution without sucrose (prepared from 'Analar' salts and 'Pyrex' glass-distilled water) and sterilized at 15 lb. pressure for 15 min. Fifty seeds, surface sterilized and washed with several changes of glass-distilled water, were germinated under sterile conditions and transferred aseptically to each flask. After five days growth at room temperature (30–32° C.), the plants were carefully removed without leaving any rootlets on the filter papers. The possibility of bacterial or fungal contamination of the test plants was checked at every stage by plating and microscopic examination. The filter papers were finely ground with 80 per cent alcohol, the extract centrifuged and the supernatant concentrated for analysis.

The technique of ascending chromatography of Williams and Kirby[2] as modified by Lakshminarayanan[3] for unidimensional chromatograms was used to study the constituents of the exudates positive to ninhydrin employing *n*-butanol/acetic acid/water (4 : 1 : 5) as the solvent mixture. As anticipated, several free amino-acids were present in the root exudates of both the resistant and susceptible strains. Their relative concentrations in each exudate were determined by visual observation of the intensity of the spots developing on the chromatogram (Table 1).

Table 1

Material	Amino-acids	Relative concentration	R_F-values
Resistant	Cystine	+ + +	0·033
	Asparagine	+ + + +	0·073
	Aspartic acid	+ +	0·140
	Glutamic acid	+	0·176
	Tyrosine	+	0·320
	Methionine	+	0·376
	Tryptophan	+	0·446
	Lysine	+	0·602
Susceptible	Aspartic acid	+	0·140
	Glutamic acid	+	0·170
	Tryptophan	+	0·440
	Lysine	+	0·602

The extracts from the control flasks where no plants were grown gave negative reactions to ninhydrin.

The results indicate that the four amino-acids found in the root exudates of the susceptible strain, namely, aspartic acid, glutamic acid, tryptophan and lysine, were also present in the root exudate of the resistant strain, almost in the same concentrations. However, the latter had four other amino-acids as well, namely, cystine, asparagine, tyrosine and methionine. Of these, cystine and asparagine were exuded in high concentrations. This result is significant, especially in view of an earlier report from this laboratory on the presence of cystine in strains of cotton resistant to *Fusarium vasinfectum* wilt[4]. Such differences in the composition of root exudates of resistant and susceptible varieties have no doubt great influence on their specific rhizosphere microflora, and indeed further work in this direction appears to be a promising field of inquiry into the mechanism of resistance to root diseases in general.

We are indebted to Prof. T. S. Sadasivan and Dr. C. V. Subramanian for helpful suggestions.

The Heterotrichous Habit in the Protonema of the Bryales

DURING recent investigations on the development in aseptic culture of a range of typical representatives of the Bryales (species of twelve genera, from six orders) we have found that the protonema possesses a more definite morphological pattern than would appear to have been appreciated previously. Examination of the advancing edge of isolated cultures growing on a solid substratum (Knop's agar or filter paper moistened with Knop's solution) has shown that in all the species studied, with the one exception of the aquatic moss *Cinclidotus fontinaloides* (Hedw.) P. Beauv., there is a striking distinction between a horizontal system of filaments creeping in or on the substratum and an aerial system of filaments arising vertically or obliquely from the horizontal system. This "heterotrichous habit", to use a term employed by Fritsch[1] for the corresponding condition in the algae, is well seen in *Funaria hygrometrica* Hedw. (Fig. 1), in which the prostrate system of a well-developed protonema is formed by stout brown-walled filaments with oblique septa and few chloroplasts, while the filaments of the aerial system, on the contrary, have hyaline walls, straight septa and numerous chloroplasts.

The relative degree of development of erect and prostrate systems, although influenced to some extent by environmental conditions, shows characteristic differences in the individual species, and some of the cultures are readily distinguished by their external appearance. In *Funaria* the prostrate system is extensive, while the filaments of the erect system are low and fairly widely spaced; but in a number of species (*Ceratodon purpureus* (Hedw.) Brid. (Fig. 1), *Pohlia nutans* (Hedw.) Lindb., *Leptobryum pyriforme* (Hedw.) Wils., *Bryum capillare* Hedw. and *Eurhyncium riparioides* (Hedw.) Jennings) although the prostrate system is still quite extensive, the aerial system is considerably better developed than in *Funaria*. The erect branches arise close together in this group of species and frequently become intertwined to form vertical tufts which rise from the medium like a miniature forest of pine trees. In *Pleuridium acuminatum* Lindb. (Fig. 1) and *Tortula muralis* Hedw. (Fig. 2) the prostrate system spreads very slowly and there is a corresponding increase in the aerial system, which undergoes an extensive development.

In all cultures, the filaments of the erect system have the characteristics of typical chloronema[2]; but those of the prostrate system are often somewhat different, and may have brown walls and oblique septa, although this distinction is not always as marked as in the case of *Funaria*. The aerial filaments are highly sensitive to light and markedly positively phototropic; but we have made no study of the factors responsible for the horizontal position of the prostrate system. A third tropic response is shown, in some of the cultures, by filaments which grow vertically downwards in the medium. These filaments have sometimes the morphological characteristics of typical rhizoids (for example, in *Ceratodon* (Fig. 1)); but frequently as in *Tortula muralis* (Fig. 2) they are merely narrower and paler than the normal chloronema filaments.

In *Cinclidotus* the growth pattern of the protonema differed considerably from that found in the other genera, and on all media the spores gave rise to compact, dark-green more or less globular masses which were formed from markedly short-celled irregularly branched filaments. Since the cultures produced numerous buds and leafy shoots, it is not unlikely that even under natural conditions the protonema of *Cinclidotus* may show a similar anomalous development.

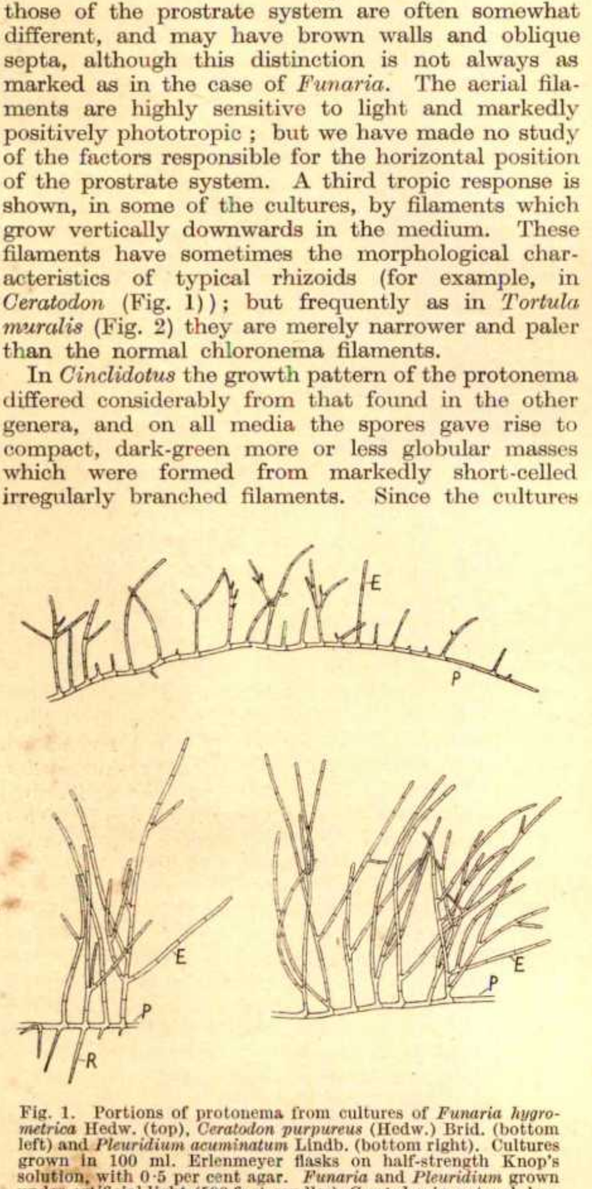

Fig. 1. Portions of protonema from cultures of *Funaria hygrometrica* Hedw. (top), *Ceratodon purpureus* (Hedw.) Brid. (bottom left) and *Pleuridium acuminatum* Lindb. (bottom right). Cultures grown in 100 ml. Erlenmeyer flasks on half-strength Knop's solution, with 0·5 per cent agar. *Funaria* and *Pleuridium* grown under artificial light (500 foot-candles) *Ceratodon* in natural daylight. *E*, Erect branches; *P*, prostrate system; *R*, rhizoidal branch. (*Funaria* × *c*. 15; *Ceratodon* and *Pleuridium* × 23)

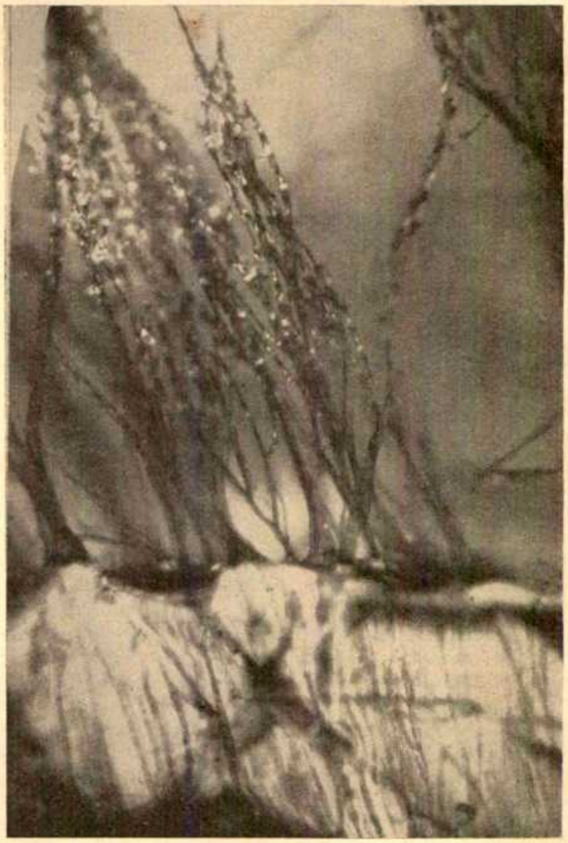

Fig. 2. *Tortula muralis* Hedw. Photograph of vertical slice through culture grown on half-strength Knop's solution with 1 per cent agar in culture tube under artificial light (500 foot-candles). Prostrate system, not clearly shown, lies between the stouter branches of the aerial system and the thinner branches penetrating downwards into the medium (× 64)

The course of bud formation was followed in detail in all the species in culture. Various arrangements of the buds were observed; but in most species the buds developed singly towards the base of the aerial filaments.

Although the heterotrichous habit is more marked in a well-grown protonema than in the earliest stages following spore germination, we have found no evidence of a distinct *caulonema* or bud-bearing stage of the kind described by Sironval[3] for *Funaria*. Sironval claimed that exposure to natural daylight is necessary for the formation of caulonema and consequently of moss buds; but in all our cultures buds were formed as readily in artificial light (500 ft.-candles) as in natural daylight.

We are indebted to Mr. G. Barker for the photograph reproduced in Fig. 2.

Crossing of Two Allopatric Populations of *Culex fatigans* Wiedemann

Two colonies of *Culex fatigans* are maintained in the insectary: one from Lagos, the other from British Guiana (obtained through the kindness of Dr. L. J. Charles). The two strains were subject to a preliminary taxonomic examination and to experimental crossing.

There was no difference in the morphology of adults or pupæ of the two strains. There was no constant difference in the morphology of the 4th instar larvæ except for the presence of black tips on the anal papillæ of larvæ from British Guiana. Larvæ of both strains had the same survival threshold (9/1,000) when subjected to a salinity test with sodium chloride.

Two colonies were set up: British Guiana males with Lagos females and British Guiana females with Lagos males. The resulting generations were about equal in number. The F_1 generation from British Guiana mothers showed black-tipped anal papillæ in 80·0 per cent of examined larvæ. None of the F_1 generation derived from Lagos females possessed this character. Both these populations were selfed. The F_2 generation from British Guiana females had 100 per cent frequency of black-tipped anal papillæ, while none of the other F_2 generation possessed this character. On further selfing this character disappeared, however, and remained absent in further generations.

The two populations of *C. fatigans* are conspecific judging from the ease with which fertile hybrids were produced. There are, to our knowledge, no other records of experimental crossing of two allopatric populations of *C. fatigans*.

Pugnacity of Marlins and Swordfish

FROM a wide area of the sea there have been reported occasional incidents illustrating the pugnacity of marlins and swordfish. This has been supported by recent evidence from South African seas, as a result of the Second World War, when a number of ships from the East were torpedoed in the Mozambique Channel. From these vessels quantities of bales of rubber were left floating awash, and from that time many thousands have continually been stranded, over an enormous stretch of the coast of South and East Africa. A good many bales must have remained in eddies, since even to-day they continue to come ashore. It was soon noticed that many bales contained the tips of spears of marlins, and it now appears that the longer a bale remains in the sea the more broken spears it is likely to contain, for those cast ashore in recent times have held as many as four. Most of these residues have been the tips broken near the front of the spear.

Marlin must deliberately charge floating or submerged objects, intending to impale them, possibly to secure food, but possibly also from plain aggressiveness. Almost all the spear tips found have been small, indicating marlins of 5–8 ft. in length, most found 4–6 in. within the bale, indicating very considerable penetrative force. This might suggest that small marlins are more aggressive than larger fishes; but it may equally be argued that the very much more densely ossified stout spear of the large fish would be less likely to break at any point, so that larger fish would have more hope of withdrawal. That large marlins also have this habit is indicated clearly by a bale recently found, in which was found embedded, to a depth of 13 in., virtually immovable, the apical 24 in. of the stout spear of a black marlin that could not have been less than 11 ft. in length with a weight of probably 400 lb. It is clear that to drive so stout a spear into a floating bale of resistant rubber so deeply, the fish must have been moving at great speed. It is equally clear that it must have taken very great force to break so stout a spear near its base in the skull, and the clue to what had happened was furnished by some teeth of a large shark (probably *Carcharinus*) also found embedded in the same bale. This marlin paid dearly for its pugnacity. Hampered by the heavy bale in that position, it would neither be able to withdraw the spear nor break so stout a bony rod. Its struggles must soon have attracted sharks, abundant in East African seas, that in increasing numbers would rapidly have torn it to pieces and become blood crazed in the process. In the mêlée one of them must have seized the bale of rubber and it was doubtless this that provided the extra force needed to fracture the stout spear. It was from this chance that the bale in question still retained sufficient buoyancy to reach the shore. In most such cases the weight of the severed head or of the skull of a large marlin would cause the bale to sink.

In one bale was also found the undoubted sword of the broadbill swordfish (*Xiphias*), indicating a similar habit for that species.

It was from this evidence that I had earlier come to believe that marlin were abundant in south-east African seas, as has been amply proved in recent times.

Light Energy and Brightness Sensation

ENGINEERING problems demand a knowledge of the relation between energy stimulus and the resulting sensation. In the field of acoustics, scales of 'loudness' have been derived which are of engineering value.

In the field of lighting and vision, the derivation of scales of apparent brightness is made more difficult by the influence of adaptation and simultaneous contrast. The sensation which is given by a patch of given luminance (physical brightness) depends not only on the energy emitted from the patch but also on the luminances of the neighbouring parts of the field of view. Abribat[1] showed how a scale of apparent brightness, which took adaptation into account, could be derived from just noticeable differences. Data obtained by Pitt[2] using a binocular matching technique enabled scales of apparent brightness to be drawn up independent of the questionable Fechner integration. Hopkinson[3] derived a scale of apparent brightness from supra-threshold contrast judgments.

A new set of determinations of apparent brightness has recently been completed for a limited number of observers, following a discussion with Prof. S. S.

Stevens of Harvard University. The results are of interest in that they show certain affinities with and certain differences from the 'loudness' scales referred to above. In these determinations, direct estimations of brightness were made both of an adapting field covering 120 deg. and of a 2 deg. patch the luminance of which could be independently adjusted. The method used was similar to that described by Stevens[4]. Among the conclusions which can be drawn from the results are :

(1) The relation between the physical luminance of the 2-degree field alone and the resulting sensation of brightness follows approximately but not exactly the relation,

$$M = kL^{0 \cdot 3}$$

where M is the magnitude of brightness sensation as judged by the subject and L is the physical luminance of the 2-degree field.

(2) When the 2-degree patch is seen in the adapting field, the exponent of L varies with the luminance of the adapting field, increasing from 0·3 in a dark field to 1·0 at an adapting luminance of 450 foot lamberts.

(3) At high adaptation-levels, therefore, brightness sensation as determined by direct judgment bears a linear relation to physical luminance. Two luminances which appear the one 'twice as bright' as the other are actually related, at high adaptation-levels, by the ratio of two to one in luminance whereas when seen in dark surroundings they are related more nearly by a ratio of 10 : 1 luminance.

These conclusions agree with those derived from the supra-threshold contrast data[3] although there are significant differences between some of the data.

The relation $M = kL^{0 \cdot 3}$ is precisely the relation which Stevens and others have published for the relation between loudness and sound energy-level.

The third conclusion appears to be new, and to have no counterpart in the field of sound. On the other hand, most of the systematic loudness judgments were made in anechoic rooms, which might correspond to the visual condition of 'dark surround'.

Mutarotation of Poly-L-proline

The synthesis and some of the properties of poly-L-proline were described recently[1]. A sample with an average degree of polymerization $n = 67$ which was obtained by bulk polymerization, dissolved in glacial acetic acid and precipitated with ether, gave the following specific rotations: $[\alpha]^{20}_{D}$ −483° (c. 1·5 in formic acid), $[\alpha]^{20}_{D}$ −372° (c. 2·0 in glacial acetic acid) and $[\alpha]^{20}_{D}$ −353° (c. 2·0 in water). As will be shown however, the optical rotation of a solution of poly-L-proline depends both on the history of the sample and on the manner in which the solution was prepared.

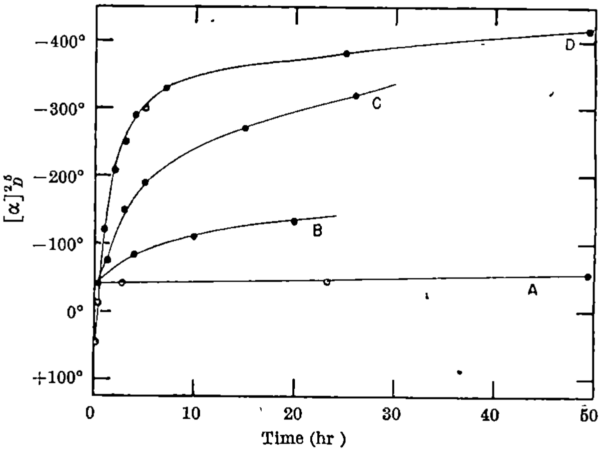

Fig. 1. Mutarotation of poly-L-proline (average degree of polymerization n = 75) in pyridine–water mixtures at 25° C. The solutions were obtained by diluting 1 ml. of the original pyridine polymerization mixture to 10 ml. with pyridine and water. Curves A, B, C and D give the mutarotation in solutions containing 10, 20, 30 and 90 per cent by volume of water, respectively

N-Carboxy-L-proline anhydride[1] (5 gm.) was polymerized in pyridine (50 ml.) for three days at room temperature. Dilution of 1 ml. of the polymerization mixture with 9 ml. pyridine gave a clear solution with $[\alpha]^{25}_{D}$ −24°. The optical rotation of this solution did not change for several days at room temperature. A solution obtained by dilution of 1 ml. of the polymerization mixture with water to a volume of 10 ml. showed a rapid change in optical rotation with time. Within 50 hr. at room temperature the specific rotation changed from $[\alpha]^{25}_{D}$ +48° (2 min. after mixing) to $[\alpha]^{25}_{D}$ −420° (Fig. 1, curve D). Curves A, B and C show the change of the optical rotation with time in different pyridine-water mixtures. Fig. 1 demonstrates that the rate of mutarotation increases with the concentration of water in the medium.

When poly-L-proline was precipitated from the pyridine polymerization mixture with ether a white powder was obtained which was insoluble in pyridine, only partly soluble in water, and readily soluble in formic acid and acetic acid. An average degree of polymerization $n = 75$ was derived from end-group analysis. The change of the optical rotation with time at room temperature of the precipitated material

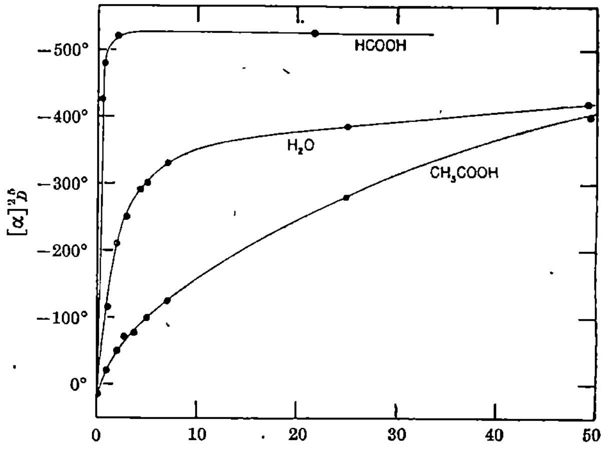

Fig. 2. Mutarotation of poly-L-proline (n = 75) precipitated by ether from a pyridine polymerization mixture in formic acid, acetic acid and water at 25° C.

dissolved in formic acid, acetic acid and water is shown in Fig. 2. Mutarotation in glacial acetic acid solution was also observed in a poly-L-proline preparation obtained by polymerization in dioxane using triethylamine as initiator.

When the poly-L-proline sample obtained from the pyridine polymerization mixture by ether precipitation was dissolved either in hot glacial acetic acid or in metacresol at 100° C. and reprecipitated from the cooled solutions by ether, it was found to dissolve readily in water. It gave $[\alpha]^{25}_{D}$ $-500°$ (*c.* 0·5 in water), $[\alpha]^{25}_{D}$ $-450°$ (*c.* 0·5 in glacial acetic acid) and $[\alpha]^{25}_{D}$ $-525°$ (*c.* 0·5 in formic acid).

In seeking an explanation of the above phenomena, a change in the chemical structure of poly-L-proline under the conditions leading to mutarotation can be ruled out. This is supported by the observation that all the forms of the polymer, on acid hydrolysis, yielded L-proline quantitatively. It seems reasonable therefore that the change in optical rotation is due to a change in the spatial configuration of the macromolecule, connected possibly with a *cis–trans* transformation in the amide bond.

A helical structure based on the *trans*-form of the amide linkage was established for the highly lævorotatory form of poly-L-proline by Cowan and McGavin[2] from the X-ray diffraction pattern given by oriented films of this polymer. It seems likely that the molecules of the highly lævorotatory form of the poly-L-proline have a similar helical structure also in water, acetic acid and formic acid. The poly-L-proline obtained in pyridine as described above probably represents an unstable form which changes into the more stable form under the influence of formic acid, acetic acid or water.

Solubility of Albumin in Alcohol after Precipitation by Trichloroacetic Acid: a Simplified Procedure for Separation of Albumin

RADIOACTIVE proteins are prepared for counting in many laboratories[1-3] by slight modifications of the basic technique of precipitation with 10 per cent trichloroacetic acid, several washes with 5 or 10 per cent trichloroacetic acid, treatment with hot alcohol, hot alcohol–ether and drying with ether. When it is required to remove nucleic acids, the protein is treated with 5 per cent trichloroacetic acid at 90° for 15 min. before the hot alcohol wash.

During an experiment in which rat serum proteins were being prepared for counting, we noticed that some of the protein precipitated by trichloroacetic acid dissolved in the absolute alcohol. We have observed this phenomenon repeatedly while preparing other samples for counting, but only if albumin is one of the proteins present. Albumin is also soluble in other solvents (acetone, ether) after precipitation by trichloroacetic acid and continues to be soluble even if higher concentrations of the acid are used to precipitate the protein. The precipitated albumin is only soluble in alcohol or the other solvents if a small amount of acid is present. Trichloroacetic, hydrochloric and acetic acids all work well in this respect. Treatment with 5 per cent trichloroacetic acid at 90° for 15 min. did not entirely prevent the albumin from dissolving in the absolute alcohol.

If the proteins are boiled, albumin will no longer dissolve in the acid-alcohol. It seemed possible that precipitation by trichloroacetic acid did not denature the albumin. Rat serum was therefore precipitated with 10 per cent trichloroacetic acid, centrifuged, the acid poured off and absolute alcohol added. (The drop of acid remaining in the pellet is sufficient acid for our purpose.) The pellet was stirred and the undissolved protein spun down and the clear supernatant dialysed against distilled water for 24 hr. The dialysate was lyophilized and the dry protein powder examined. All the dry protein obtained by this means dissolved readily in water. Paper electrophoresis in 0·05 *M* veronal buffer at *p*H 7·4 and at *p*H 8·6 resulted in a single spot which was unretarded when compared with rat serum albumin separated by the Cohn procedure[5] and with the albumin spot of rat serum. Addition of rabbit serum immunized with rat serum albumin produced precipitation of our albumin from the solution whereas rabbit serum without antibody caused no precipitation. The protein obtained by the method outlined appears to be undenatured rat serum albumin. Preliminary experiments indicate that the albumin is not contaminated by other proteins. Similar findings were obtained with bovine albumin and human serum albumin.

We believe this simple procedure offers the basis for a rapid separation of serum albumin and a method for the detection and quantitative estimation of albumin in mixtures of other proteins, and we expect to publish full details of such methods at an early date. Meanwhile, we point out the necessity for care when preparing proteins for counting by the conventional techniques, especially if they contain albumin.

Molecular Weight Determination of Components by Gas-Phase Chromatography

THE gas-density balance apparatus developed by Martin and James[1] for detection and estimation of components in gas-phase chromatography might be used for a rapid process for evaluating the molecular weights of single components.

It has been shown that in a detector, which makes use of a gas-density balance, if the densities of two gas streams coming out of two columns, one where

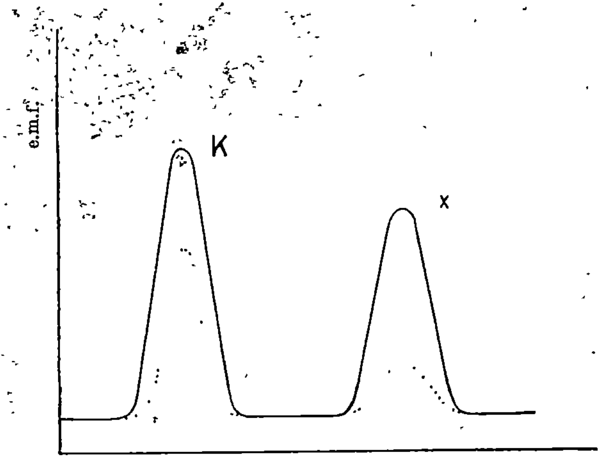

Fig. 1. Schematic diagram of a gas phase chromatogram of a mixture of a known (K) and an unknown (x) component. Heavy line, elution gas M_1; dotted line, elution gas M_2

the separation is achieved, the chromatographic column, and the other acting as a reference column, are continuously compared, the difference in density between the two gas streams can be converted into an electromotive force in a sensitive thermocouple.

The suggested procedure consists of the addition to the unknown mixture of a pure substance of known molecular weight, which is defined as the 'internal standard', and in running a chromatogram of the mixture on the same column by using two different elution gases.

To the unknown mixture, which for simplicity is assumed to consist of only one compound, x, the molecular weight of which is M_x, the 'internal standard' K (mol. wt. $= M_K$), is added and the chromatogram of the mixture by using as elution gas a gas (mol. wt. $= M_1$), will appear as in Fig. 1 (heavy line).

By replacing as elution gas one with a different molecular weight (M_2), the chromatogram will be as in Fig. 1 (dotted line). If the gas flow is kept constant, the volume of elution gas will be the same for both components; peak heights and areas will be, however, different for the different elution gases and for the different size of the sample analysed, which does not need to be known.

The density of the gas at the outlet of the reference column (reference gas: d_1) and at the outlet of the chromatographic column, when component x passes through the detector, (d_x), can be expressed in terms of the gas law equation:

$$d_1 = \frac{M_1 P}{RT} \qquad d_x = \frac{(n_1 M_1 + n_x M_x)P}{RT} \tag{1}$$

where n_1 and n_x are the mole fractions and M_1 and M_x the molecular weights of the elution gas and of the unknown component.

The density difference between the two gas streams in the detector Δd_{x-1} is:

$$\Delta d_{x-1} = \frac{n_x(M_x - M_1)P}{RT} \tag{2}$$

A similar expression is obtained by eluting with a gas of a different molecular weight, M_2:

$$\Delta d_{x-2} = \frac{n_x(M_x - M_2)P}{RT} \tag{3}$$

The amount, Q_x, of the compound, x, which was chromatographed in run A, can be expressed in terms of the volume of the gas mixture, v, coming out of the chromatographic column:

$$Q_x = \int_0^\infty \frac{n_x M_x P}{RT}\, dv$$

and by substitution of n_x value from (2)

$$Q_x = \frac{M_x}{M_x - M_1}\int_0^\infty \Delta d_{x-1}\, dv$$

The amount, q, of the compound, K, chromatographed in the same run A is given by a similar expression:

$$q_K = \frac{M_K}{M_K - M_1}\int_0^\infty \Delta d_{K-1}\, dv$$

where Δd_{K-1} is the density difference between the two gas streams when component K passes through the detector.

Similar expressions are obtained for amounts Q'_x and q'_K of compounds x and K chromatographed in another run, B.

It has been demonstrated that the e.m.f., E, of the thermocouple in the detector is proportional to the density difference at least for small density changes; this condition is fulfilled providing the sample size is in the range of a few microlitres as it is usually in gas-phase chromatography work. The integrals may be easily solved by taking:

$$\int_0^\infty \Delta d\, dv = K\int_0^\infty \Delta E\, dv$$

Experimentally Q_x, $Q'_{x'}$, q_K and q'_K cannot be directly measured with a high degree of accuracy; but since the ratio $\frac{Q_x}{q_K}$ is equal to $\frac{Q'_x}{q'_K}$ by combining the above-mentioned expressions and measuring the corresponding surface of the peaks A_x, a_K, $A'_{x'}$, and a'_K obtained in the automatic graphical registration of the chromatograms, in arbitrary units, the following expression is obtained:

$$\frac{A_x}{a_K}\left(\frac{M_K - M_1}{M_x - M_1}\right) = \frac{A'_x}{a'_K}\left(\frac{M_K - M_2}{M_x - M_2}\right)$$

which can be easily solved in terms of M_x.

This expression is valid providing the gas flow is kept strictly constant and the density changes are small.

For example, in a set of experiments carried out with a conventional apparatus using chromatographic columns, thermostated at 132°, filled with 'Celite' with which tricresylphosphate as stationary liquid was mixed, a known compound (ethylbenzene $M_K = 106{\cdot}2$), used as internal standard, was mixed with a hydrocarbon of unknown molecular weight (dodecane $= M_x = 170{\cdot}3$, nitrogen ($= M_1$) and hydrogen ($= M_2$) were used as elution gases; areas were measured in arbitrary units).

The following results have been obtained:

$\left[\frac{A_x}{a_K}\right]$	$M_1 = N_2$	$\left[\frac{A'_x}{a'_K}\right]$	$M_2 = H_2$	M_x
2·24		2·06		
2·25	Average	2·04	Average	
2·28	2·27	2·04	2·03	163
2·30		2·00		

The theory has been checked on many compounds in vapour-phase partition chromatography by using as elution gas hydrogen, nitrogen or carbon dioxide. By taking a convenient standard, an accuracy of about 4 per cent can be obtained.

Details of the apparatus, of the experimental data and the calculations will be published elsewhere.

One of us (A. L.) is greatly indebted to Dr. A. J. P. Martin and to his staff of the Medical Research Council for information and advice given to him in the building of the gas-density balance meter.

An Unexpected Catalytic Dehydrogenation

During the course of an investigation which is being made on the decomposition of amines in the presence of hydrogen over evaporated metal-film catalysts, an unexpected example of selective catalytic action has been observed. The decomposition of cyclohexylamine on evaporated platinum films at 134° C. was expected to produce cyclohexane and ammonia according to the equation

$$C_6H_{11}NH_2 + H_2 \rightarrow C_6H_{12} + NH_3 \qquad (1)$$

The reaction was followed by continuous mass-spectrometric analysis of the reacting gases by a technique described elsewhere[1]. As the ions of mass 99 ($C_6H_{11}NH_2^+$) decreased in number, ions of mass 17 NH_3^+) appeared but very few ions of mass 84 $C_6H_{12}^+$) were observed. A search throughout the mass-range covered by the spectrometer indicated hat large quantities of ions of mass 78 were being produced, suggesting that the primary product of the reaction was benzene (C_6H_6) rather than cyclohexane. Now the position of the equilibrium[2] in the reaction

$$C_6H_{12} \rightleftharpoons C_6H_6 + 3H_2 \qquad (2)$$

s well over on the side of cyclohexane under the onditions used in this work. The initial reaction mixture consisted of 1·8 mm. cyclohexylamine and 23 mm. hydrogen and, assuming complete conversion ccording to reaction (1) and the known equilibrium onstant for reaction (2), the maximum pressure of benzene to be expected at 134° C. was only about 10^{-3} mm. The identification of the source of the mass 8 ions as benzene was therefore considered tentative ntil it was found that when most of the cyclohexylamine was used up the ions of mass 78 began o disappear again and in turn substantial quantities f ions of mass 84 were formed. This showed that he normal catalytic hydrogenation of benzene to cyclohexane, to be expected on a metal like platinum, was then taking place. The formation of benzene as also confirmed by stopping a typical reaction nd identifying the benzene in the reaction mixture y vapour-phase chromatography. The whole course f the reaction is shown in Fig. 1.

The initial reaction can be written as

$$C_6H_{11}NH_2 \rightarrow C_6H_6 + NH_3 + 2H_2 \qquad (3)$$

which is the sum of reactions (1) and (2). Although e equilibrium constant for reaction (1) is not nown, it is probably of similar magnitude to that for the corresponding hydrogenation of methylamine to methane and ammonia which is approximately 10^{12} at 134° C. Combining this figure with the known equilibrium constant[2] for reaction (2), a value of 10^{13}(mm.)^3 is found for reaction (3). The magnitude of this value indicates that it is thermodynamically feasible for benzene to be formed according to reaction (3) even in the presence of a large excess of hydrogen.

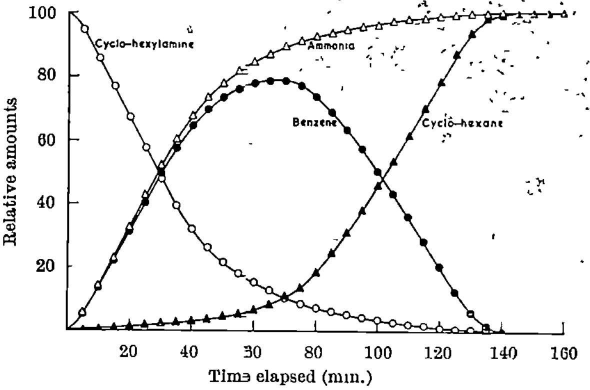

Fig 1. Relative amounts of cyclohexylamine, ammonia, benzene and cyclohexane during reaction of 1 8 mm. cyclohexylamine and 23 mm. hydrogen on a 5·65 mgm evaporated platinum catalyst at 134° C.

The selective action of the catalyst causes reaction (3) to take place in preference to reaction (1). It is not perhaps surprising that benzene should be produced on the surface of the catalyst since it is known that saturated hydrocarbons can lose hydrogen atoms on transition metal catalysts in this temperature-range. However, it is most interesting that the presence of the amine can inhibit the hydrogenation of benzene which is usually a facile catalytic reaction. Further work is in progress to elucidate the details of this type of phenomenon in connexion with the vapour-phase decomposition of cyclic amines on evaporated metal-film catalysts and will be published in due course.

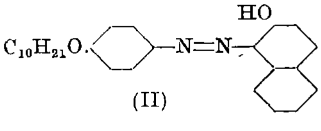
Benzene-soluble Aryldiazonium Salts

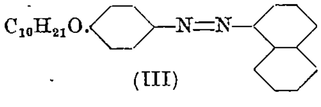
While typical salts are soluble in water and insoluble in hydrocarbons a few are soluble in both media. No member of the large and important group of diazonium salts is known to be soluble in weakly polar media, however, and this has prevented a study of the reaction of the salts with such reagents as the organometallic compounds, though their complexes with metallic salts have been used[1,2].

We have now found that *p*-*n*-decyloxybenzenediazonium toluene-*p*-sulphonate, *p*-cetyloxybenzenediazonium chloride and 2 : 5-di-*n*-*p*-decyloxybenzenediazonium chloride are all moderately soluble in warm benzene, though sparingly in the cold. The salts appear to exist in benzene as ion pairs, though more complex association compounds of molecules and ions may be present also. Thus they react easily with β-naphthol in the same solvent, in the presence of a small proportion of pyridine (1 mole), to form normal azo-compounds. *p*-*n*-Decyloxybenzenediazonium toluene-*p*-sulphonate (I) gives 1-(*p*-*n*-decyloxyphenylazo)-2-naphthol (II), a scarlet, crystalline compound. The salts also react very readily with typical Grignard reagents. α-Naphthylmagnesium bromide and (I) give 1-(*p*-*n*-decyloxyphenylazo)naphthalene (III), though only in 10–30 per cent yield, the highest yields being obtained at 60° and the lowest at the room temperature. In addition, the reaction gives *p*-*n*-decyloxydiphenyl (IV) (25–30 per cent), *n*-decyloxybenzene (V) (5–7 per cent), and naphthalene (30–40 per cent). There was no indication of the formation of diphenyl, 4 : 4′-di-*n*-decyloxydiphenyl, 1-(*p*-*n*-decyloxyphenyl)naphthalene, 1-phenylnaphthalene, 1 : 1′-dinaphthyl, *p*-*n*-decyloxyazobenzene or 4 : 4′-di-*p*-*n*-decyloxyazobenzene.

(I)



(II)



(III)

(IV)

(V)

The azo-compound (III) is the expected product of an ionic reaction between α-naphthyl anions and diazonium cations, but the formation of (IV), (V) and naphthalene appears to require the intervention of radicals.

Analogously, the same diazonium salt (I) and phenylmagnesium bromide gave *p*-*n*-decyloxyazobenzene, but the most abundant of the isolated products was *p*-*n*-decyloxydiphenyl (IV).

Occurrence of Substances Similar to Gibberellic Acid in Higher Plants

If the fungal metabolite gibberellic acid is applied to dwarf varieties of pea, french bean (*Phaseolus*), broad bean (*Vicia*) or maize, growth is greatly accelerated and plants similar to the normal tall phenotype are produced; the tall varieties themselves are much less affected by gibberellic acid, if at all[1,2]. This suggests that this acid, or a substance with similar physiological properties, is a normal plant-growth regulator, produced less abundantly in dwarf varieties than in tall ones. The growth-promoting substance obtained from immature bean seeds by Mitchell, Skaggs and Anderson[3] was probably of this type; more recently, West and Phinney[4] have reported the probable occurrence of substances like gibberellic acid in seeds of several plant species; I have obtained evidence of such a substance in the shoots of dwarf and tall peas, and this is summarized below.

Shoots of pea seedlings grown in a greenhouse were frozen to − 15° C. and broken down to a coarse powder. This was covered with ethyl alcohol and stored at 0° C. overnight. The solvent was separated by filtering and pressing the plant material. The ethyl alcohol was then distilled off *in vacuo*, and the aqueous residue was filtered and extracted with ethyl acetate at *p*H 3. This was distilled off *in vacuo* over 30 ml. distilled water in order to precipitate water-insoluble material which had been carried over; the aqueous solution so obtained was filtered and extracted with fresh ethyl acetate, which was concentrated and spotted on chromatography paper The paper was eluted with water and the resulting eluate was acidified to *p*H 3 and extracted with ethyl acetate or ether. This was distilled off *in vacuo* and the residue was taken up in 0·25 ml. ethyl alcoho and spotted on 2-cm. wide strips of chromatography paper. These strips were run in a descending solvent system consisting of chloroform/ethanol/water/formic acid in the proportions 20 : 4 : 2 : 1.

The chromatograms were tested for gibberellic acid-like activity by an assay based on growth o sections of the first leaf of etiolated wheat seedlings Gibberellic acid produces little or no response in the coleoptile assays used for auxins, but leaf sections were shown by Hayashi and Murakami[5] to respond to gibberellin *A*, a substance similar in chemical and physiological properties to gibberellic acid. Four-day old wheat shoots, grown in the dark at 23° C., were cut close to the seed; 4 mm. sections were cu through both coleoptile and leaf 4 mm. from the base of the leaf. The chromatograms were divided into a number of pieces, which were moistened with water. Ten sections, each consisting of a leaf section still enclosed in a coleoptile section, were placed on each piece of paper and were incubated in a mois atmosphere in the dark at 23° C. for 48 hr. The final length of the leaf sections was measured with the aid of a projector. The wheat leaf test is exceedingly sensitive to gibberellic acid; sections on pape moistened with water increase in length by abou 5 mm.; in 3 × 10^{-6} *M* gibberellic acid length increas is of the order of 7 mm. and even concentrations c 10^{-8} *M* cause an appreciable growth increase ove controls. Growth is slightly enhanced by indoly acetic acid, but only at considerably higher concentrations. This test is thus to some extent specifi for gibberellic acid and related compounds.

Approximate R_F values for gibberellic acid and several auxins, using the solvent system described above, were: gibberellic acid, 0·46; indolyl aceti acid, 0·83; indolyl acetonitrile, methyl indolyl acetate and indolyl butyric acid moved with th solvent front. In a number of experiments, extract of shoots of two varieties of pea, Meteor (dwarf) and Improved Pilot (tall), have consistently shown chromatogram zone of growth stimulation corresponding in R_F to gibberellic acid. Some chromatogram of pea extracts have also shown an active zone simila in R_F to indolyl acetic acid; but growth-inhibitin substances, which are also found in the extracts, usually mask that area of the chromatogram.

Similar chromatograms sprayed with ethanolic Salkowski reagent showed no coloured spot typical of an indole compound, neither did they show the fluorescent zone characteristic of gibberellic acid after spraying with ethanolic sulphuric acid. This does not necessarily imply absence of indole compounds or gibberellic acid, but may be due to very low concentrations of such compounds on the paper.

The Square Pyramidal Configuration in a Five-Co-ordinate Nitrosyl Complex

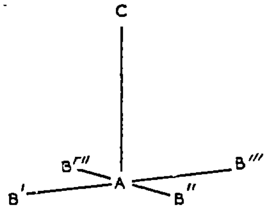
MOST molecules which have a five-co-ordinated central atom, and the structures of which have been accurately determined, have the shape of a trigonal bipyramid; for example, PF_5, $(CH_3)_3SbBr_2$, $Fe(CO)_5$. Nevertheless, in their study of valency theory, Daudel and Bucher[1] predicted that a five-co-ordinate molecule may in certain circumstances have a square pyramidal configuration. In their configuration (I), the central atom *A* is strongly bound to four atoms *B* at the corners of a square, these five atoms being co-planar; this square forms the base of a pyramid, and the fifth atom *C*, which is more weakly bound, is at the apex. They considered that this configuration would be most stable when the lower *d*-orbitals of the central atom are used in forming the bonds, that is, when the hybridization is dsp^3 rather than sp^3d.

Apart from the compound $[Ni(PEt_3)_2Br_3]$ prepared by Jensen and Nygaard, which is too unstable for detailed study but probably is square pyramidal, only two examples of this configuration appear to be well established. The infra-red and Raman spectra of iodine pentafluoride IF_5 require the molecular symmetry C_{4v}, that is, the configuration is square pyramidal, but the central iodine atom does not necessarily lie in the basal plane of the pyramid. The only example of this type of co-ordination which has so far been examined by X-ray crystallographic methods is K_2SbF_5, where the antimony atom appears to lie slightly below the basal plane of the square pyramid; the limits of accuracy claimed for this determination are rather wide, and it is not certain that this apparent departure from Daudel and Bucher's configuration is real. The molecule IF_5 and the ion $(SbF_5)^{=}$ are isoelectronic and in both cases the bonds must involve the upper *d*-orbitals of the central atom. It is simplest to regard the co-ordination as distorted octahedral, with one position occupied by a lone pair of electrons[2], the hybridization being sp^3d^2.

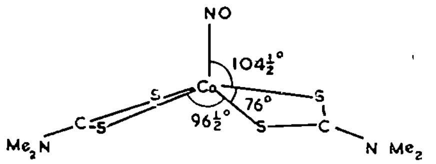
A molecule which fulfils more closely the conditions envisaged by Daudel and Bucher is *bis*-(NN-dimethyl dithiocarbamato)nitrosyl cobalt (II), $[Co(S_2CNMe_2)_2(NO)]$, and we have therefore determined its structure by X-ray crystallographic methods. It was first prepared by Malatesta, and Cambi reported it to be diamagnetic[3]; all the electrons are therefore paired, indicating that lower *d*-orbitals are used for σ-bond formation.

The crystals of this compound are monoclinic, space group $P2_1/c$, with four molecules in the unit cell; $a = 6{\cdot}49 \pm 0{\cdot}02$ A., $b = 13{\cdot}51 \pm 0{\cdot}05$ A., $c = 16{\cdot}95 \pm 0{\cdot}05$ A., $\beta = 116\frac{1}{2}°$. They were obtained by the slow evaporation at room temperature of a solution in chloroform, one of the few solvents in which the substance is appreciably soluble. The crystals, which form as prisms elongated along the *a*-axis, are opaque to light even when their thickness is as small as 0·01 mm. Their surfaces are highly reflecting like metallic mirrors, which indicates that some electrons in the molecule are bound rather loosely. All the crystals so far obtained have been twinned, and the X-ray analysis has therefore been limited to a study of the projections down the *a*- and *b*-axes.

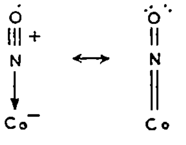
The crystal consists of discrete molecules, without any evidence of strong intermolecular forces. It became apparent very early in the analysis[4]—and subsequent refinement has confirmed—that the configuration of the molecule is indeed that of a square pyramid, or rather of a rectangular-based pyramid; but it is not exactly the configuration described by Daudel and Bucher. The central cobalt atom does not lie in the same plane as the sulphur atoms, but about 0·5 A. above it (II). The average cobalt–



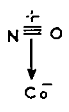
I



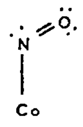
II



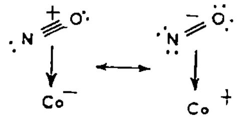
III



IV



V



VI

sulphur distance is 2·31 A., which is reasonably close to the sum of the octahedral radius for Co(II) and the tetrahedral radius for sulphur, 2·36 A. The inter-bond angles around the cobalt atom at the present stage of the analysis are shown in diagram II. The configuration is very similar to those derived theoretically, by two different methods, by Kimball[5] and by Linnett and Mellish.

The process of refining the structure so as to establish the positions of the lighter atoms is now nearing completion, and full details of the methods used and of the final results will be submitted for publication elsewhere. It is already clear that the nitric oxide group is not perpendicular to the basal plane of sulphur atoms, with the cobalt, nitrogen and oxygen atoms collinear (III), as has hitherto been supposed by analogy with carbonyl complexes[6]; nor is it parallel to the basal plane (IV), as in the π-type complexes, for example, of ethylene[7]. It lies between these two orientations, being inclined at an angle of approximately 135° to the vertical axis of the pyramid, and appears to be bound either by forming an electron-pair bond (V), or by the donation of π-electrons to the metal atom, the atoms being arranged unsymmetrically because of the difference between their electronegativities (IV). The existence of unsymmetrical π-complexes has already been shown by Holden and Baenziger's work on styrene palladous chloride[8], and we are indebted to Dr. L. E. Orgel for confirming that this type of bond can be justified on theoretical grounds in nitric oxide complexes. The arrangements in diagrams V and VI would both result in diamagnetism, but the angle Co—N—O of 135° is rather larger than would be expected for structure V. Structure VI fits our results better, but at the present stage of the analysis it is not possible to distinguish between V and VI with certainty.

We are indebted to Dr. J. Chatt, Dr. L. A. Duncanson and Dr. L. M. Venanzi, who also prepared the compound for us, for discussions on the structure.

Photo-reduction of Pteridines

WHEN a solution of 7-hydroxypteridine[1] was spotted on a sheet of Whatman No. 1 filter paper, irradiated with ultra-violet light (principally 254 mμ) for 5 min., and developed (by ascending chromatography) in various solvents, two spots appeared. One of these was identical with the starting material (unirradiated material was used as a control on the same piece of paper), and the other proved to be 5 : 6-dihydro-7-hydroxypteridine[1]. This reaction did not take place in aqueous solution (although 2 : 6-dihydroxypteridine[2] undergoes photochemical change in water), but it did if allyl-thiourea was present as a hydrogen donor (unirradiated controls were not reduced). 2- and 4-hydroxypteridine were found also to be photo-altered on paper; but the products have not yet been identified.

Photosensitive pteridine pigments are believed to be important in the visual process of insects[3]. It will be interesting to see if a cycle of photo-reduction followed by enzymic oxidation is involved.

Optical Properties of 'Cellophane'

SOME years ago, one of us[1] used commercial 'Cellophane' in conjunction with a polarizer and an analyser to produce colours in unstained microscopic sections of decalcified teeth. Subsequent investigation has shown that a sheet of this kind of 'Cellophane' exhibits the curious property of behaving like a half-wave plate. We do not think that this property can be explained in the usual way, that is, by 'Cellophane' thickness in conjunction with ordinary and extraordinary ray velocities, because it is improbable that the manufacture of commercial 'Cellophane' involves such precise control of thickness as the usual half-wave plate theory demands. We are therefore led to conclude that its surfaces are instrumental in giving 'Cellophane' this property.

If this phenomenon is indeed a surface, rather than a thickness, effect, it should appear with all colours equally. This would give 'Cellophane' the property of being a half-wave plate for all colours. In practice, when 'Cellophane' is viewed between two 'polars' it shows a definite coloration which becomes more marked when the thickness of the 'Cellophane' is increased (by using a number of sheets). This is indeed a thickness effect which makes it impossible to verify the supposed half-wave property precisely. Nevertheless, allowing for the limitations imposed by the thickness effect, we find, as already stated, that a 'Cellophane' sheet does satisfy the customary tests for a half-wave plate, no matter what colour of light be used. While the thickness effect can be explained in terms of current theory, we can think of no such explanation for an achromatic half-wave plate property dependent (as we believe) upon surfaces. Polythene sheets exhibit similar properties but less markedly.

Applications of the above-mentioned properties of 'Cellophane' and polythene to histology will be described later in the *Irish Journal of Medical Science*. We should like to thank the Medical Research Council of Ireland for apparatus used in this investigation, and Messrs. John Player and Sons, Dublin, for a generous gift of 'Cellophane'.

Threshold Potential for the Low-Frequency Electric Discharge in Air

Studies of the threshold potential[1], V_m, for low-frequency (50 c./s.) discharges in atmospheric air dried over phosphorus pentoxide were made over a range of pressure, p, from 1 to 75 mm. of mercury, using cylindrical glass tubes with plane parallel glass ends as electrodes. V_m was indicated by a sudden rise in the current flowing through the discharge tube, the initiation of a glow characteristic of the gas, and the appearance of high-frequency pulses on the current waveform.

Fig. 1 shows the variation of V_m (a.c. peak value) with the product of pressure and inter-electrode distances, d in cm., (i) for hard 'Pyrex' glass electrodes and (ii) for soft soda glass electrodes. For comparison, values of the sparking potential, V_s, are also shown (iii) for brass electrodes under 50 c./s. a.c. excitation, and (iv) for mercury-contaminated copper electrodes under d.c. excitation recently reported by Llewellyn Jones and Davies[2].

It is seen that for a given value of $p \times d$, V_m (hard 'Pyrex' glass) is greater than V_m (soft soda glass), which in turn is greater than V_s (metal). The close agreement between the present values with brass electrodes and those of Llewellyn Jones *et al.* clearly indicates that the above difference is not due to the use of a.c. Moreover, the larger values of V_m with glass electrodes cannot be attributed to a difference in the work function of the electrodes, because differences in the breakdown potential for cathodes of different work function are a maximum near the minimum sparking potential and tend to become zero for higher pressures. In the present case, however, the difference $V_m - V_s$ is found to increase with $p \times d$. This difference may be attributed, at least in part, to a fall in potential on the glass electrodes depending on the resistivity, ρ, of the electrodes, which also changes in the sense that ρ (hard 'Pyrex' glass) is greater than ρ (soft soda glass) which is greater than ρ (metal).

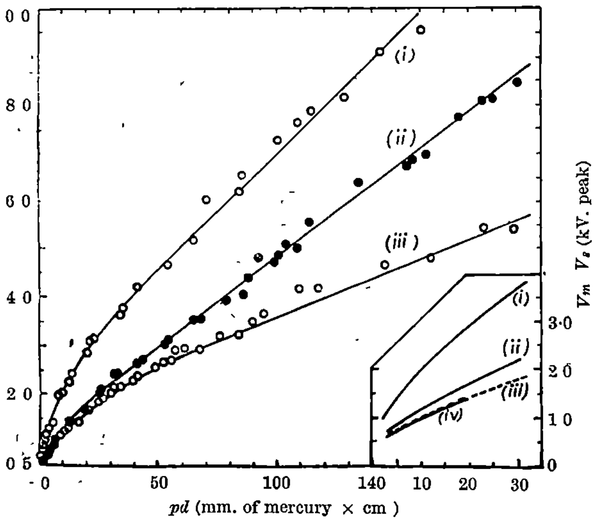

Fig. 1. Paschen's curves in air for various electrodes. (i) Hard 'Pyrex' glass electrodes ; (ii) soft soda glass electrodes ; (iii) brass electrodes ; (iv) copper electrodes (in inset), after Llewellyn Jones and Davies
(i), (ii) and (iii) : under a.c excitation ; peak values are plotted

Details of this work will be published elsewhere.

A similar difference in the Geiger threshold for Maze counters with external cathodes and that for Geiger counters with internal cathodes has been reported[3,4]. The plateau for Maze counters is also found to be appreciably longer[4]. Such results may also be due[5] to a corresponding fall in potential on the glass walls of the Maze counters.

A Compact Soil Perfusion Apparatus

Lees and Quastel[1] described an apparatus for the perfusion of soil samples which obviated the need for disturbing the soil during the experiment. Their design was later modified by Audus[2], who used a negative pressure for circulating the perfusate. This apparatus was rather fragile and required a considerable amount of incubator space. A modified design, using the same principle as the Audus apparatus, has been used here successfully for twelve months and the alterations did not apparently affect the efficiency of the perfuser compared with the earlier models.

The apparatus consisted of a 500-ml. Florence flask (Fig. 1) in which the neck was replaced by the tube D (15 cm. by 2·5 cm. internal diameter). The bottom of the tube D was constricted to prevent the soil column from falling into the flask. The side-arm C was bent at right-angles and extended up to the same height as the flask. A constriction, 1–2 mm. in diameter, was made at the point of fusion (B) to restrict the movement of liquid from C into the flask A. When the diameter of the constriction at B was greater than 2 mm., air was drawn directly into the flask rather than into the tube F. The tubes E and F had an internal diameter of 7 mm. and were fixed as shown in Fig. 1. The tube F was sealed into the right-angle bend of the side-arm C, which was found empirically to allow the optimal flow of air and perfusate into the tube F. The tube E led to a water pump and the air-flow was controlled by an adjustable clip. No constrictions in tubes E or F were found to be necessary. A piece of glass tubing (G) filled with cotton-wool was placed in the open end of the side-arm *C* to prevent aerial contamination of the perfusate and to reduce the air flow into the tube *F*. The soil sample (30–50 gm. of soil crumbs) or small glass beads were placed in the tube *D* on a pad of glass wool and another pad was placed on top to prevent puddling of the soil. The rubber bung was replaced and 300 ml. 0·01 *M* ammonium sulphate was introduced into the flask via the side-arm.

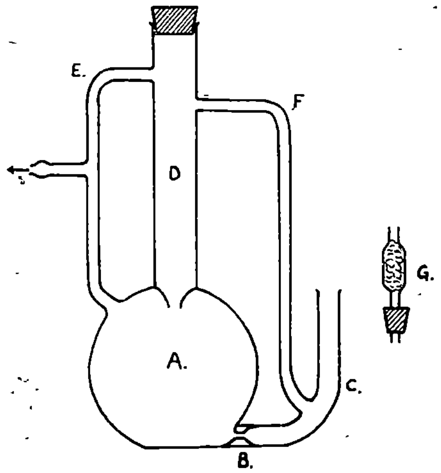

Fig. 1. Soil perfusion apparatus

The new apparatus was only 25 cm. high and could be housed in a small space as it did not require the support of a retort stand. The soil column was easily removed after the experiment by gentle shaking and the apparatus could be acid cleaned and then later sterilized in one piece, thus eliminating many of the breakages which occurred when assembling and dismantling the earlier models. The apparatus required no extensive adjustment prior to perfusion and worked for long periods without supervision. Finally, the apparatus was cheap and easy to make. The new design should be useful where large numbers of perfusers are used and the available incubator space is limited. Further details of the rate of nitrification by soils in this apparatus will be reported in greater detail elsewhere.

Thermal Conductivity of Soil

IN a recent communication[1] J. Webb overlooks that his calculation of the thermal conductivity of a cubic arrangement of spheres is based on an inadmissible simplification and in consequence he is led to a false conclusion. This is true also of Gemant's[2] article which is criticized by Webb. A rigorous analytical treatment of the identical problem in electrical conductivity was published by Lord Rayleigh[3]. Full elaboration of the theory, however, meets with mathematical difficulties.

Rayleigh's approximate formula leads to 0·00033 cal. cm.$^{-1}$ sec.$^{-1}$ deg. C.$^{-1}$ for the thermal conductivity in the numerical example discussed by Webb. From other considerations[4,5] it follows that this value is approximately 30 per cent too low. The value for a mineral dry soil at the same porosity (47·6 per cent) is about 0·0005 cal. cm.$^{-1}$ sec.$^{-1}$ deg. C.$^{-1}$ (ref. 4) and therefore practically of the same magnitude. It is trivial that both systems are not quite comparable because they have different geometry.

The theory of thermal conductivity of granular materials with special reference to soils has been discussed by me[4,5]. An approximate method for calculating the thermal conductivity of soils from their composition, moisture content and dry density has resulted. The method has been tested against a large body of consistent experimental results.

D. A. DE VRIES

Division of Plant Industry,
Commonwealth Scientific and
Industrial Research Organization,
Deniliquin, New South Wales.
Aug. 10.

[1] Webb, J., *Nature*, **177**, 989 (1956)
[2] Gemant, A., *J. App. Phys.*, **21**, 750 (1950)
[3] Rayleigh, W. R., *Phil. Mag.*, v, **34**, 481 (1892).
[4] Vries, D. A. de, *Med. Landbouwhogeschool Wageningen*, **52**, 1 (1950).
[5] Vries, D A. de, Annexe 1952–51, *Bull. Inst. Int du Froid, Paris*, 113 (1952)

IN his article, Gemant directs attention to the non-rigorous nature of his method of determining the thermal conductivity of soil. His method, which I adopted in the communication to which Dr. de Vries refers, assumes that the lines of heat flow are parallel. Quite obviously, an assumption of this kind will introduce errors which will increase as the ratio of the conductivities of the two phases increases. For dry soil this ratio is of the order of 160 : 1, and the error involved in using my formula is very considerable.

For water-logged soil the ratio of the conductivities of the two phases is of the order of 7 : 1, and my formula yields the value 0·00486 cal. sec.$^{-1}$ cm.$^{-1}$ deg. C.$^{-1}$, which compares with an observed value quoted by Gemant of 0·005 cal. sec.$^{-1}$ cm.$^{-1}$ deg. C.$^{-1}$.

It would appear probable, then, that my formula would prove adequate for a composite material, in which conducting spheres are embedded in a matrix of lesser conductivity, provided that the ratio of the conductivities of the two components does not exceed say 10 : 1. This may be of little practical significance ; but to my mind it justifies, to some extent, Gemant's treatment of the capillary wedge-shaped rings in damp as opposed to water-logged soil.

In my communication, I should perhaps have stressed the non-rigorous nature of the derived formula, instead of assuming that the interested reader would automatically consult Gemant's article in which the approximation is commented upon.

My purpose in writing initially was to challenge the validity of Gemant's method of determining the conductivity of dry soil. In this method, the air-phase conductance is neglected, and consequently it becomes difficult to reconcile the infinite value of the thermal resistivity of the hypothetical dry soil with the finite observed value for an actual dry soil. Gemant was forced to assume that the spheres were chipped to facilitate heat flow from solid to solid.

In other words, the model is tailored to suit observed values.

Using Gemant's own method, I attempted to show that the effect of the shunt air-conductance may not be neglected, with impunity, in a dry soil. That the method is not rigorous is of less concern to me than this point, namely, that the air-conductance must have a considerable influence upon the conductivity of dry soil. This does not appear to be in dispute.

Effect of 'Rindite' on the Development of the Growth-substances in Potato Tubers

THE stimulating effect of 'Rindite' (ethylene chlorhydrin – ethylene dichloride – carbon tetrachloride 7 : 3 : 1) is extensively employed to break the rest period of potato tubers and thus to obtain two crops in a year. Although several articles dealing with the metabolism of the potatoes treated with 'Rindite' are known, the development of the growth-substances in the chemically treated tubers have not yet been analysed in detail. The purpose of this study was to elucidate the effect of 'Rindite' on the changes in the concentration of the growth-substances in the tubers.

The investigation was carried out on the 'Early Yellow' variety with a four-week rest period. Part of the freshly harvested tubers were exposed to the effect of 0·8 ml./kgm. 'Rindite' for 48 hr. and, after airing, were stored in wet sand. The untreated tubers were also stored. The sprouting of the treated potatoes began on the fifth day, while those of the controls began on the 28th day. Determinations of the growth-substances in the peelings of the treated tubers were carried out every second day for 12 days, that of the controls weekly for 42 days. The growth-substances were extracted with peroxide-free ether at 4° C. and the extractions were separated into acid and non-acid fractions. Chromatograms were made with *iso*propanol – ammonia – water and the growth-substance content of each 1 cm. paper-segment was examined by the *Avena* straight-growth test. The relative concentration of the growth-substances present could be inferred from the rate of the elongation of the coleoptile sections.

On chromatograms of the acid fractions of both the treated and untreated tubers, five active areas could be observed, as shown in Table 1.

Table 1

No.	R_F value	Bio-assay effect	Identification
1	0·10	stimulation	?
2	0·24	stimulation	indole-3-pyruvic acid
3	0·40	stimulation	indole-3-acetic acid
4	0·65	inhibition	?
5	0·87	stimulation	indole-3-acetonitrile

The substance having the R_F of 0·1 is unknown, though such a slowly moving accelerator has been demonstrated by Bennet-Clark and Kefford[1,2] and Nitsch[3] in several parts of plants. The substance with an R_F value of 0·24 is presumed to be indole-3-pyruvic acid. An inhibitor with the R_F of about 0·65 has been also found by several authors[1,2,4] in numerous plants including potatoes. Similarly, the presence of indole-3-acetonitrile in potatoes was demonstrated.

During the rest period and the sprouting, the concentration of the growth-promoting substances of the acid fractions in the stimulated tubers developed differently from that in the controls. In five days following treatment with 'Rindite' the concentration of indole-3-acetic acid in the peeling rapidly rose ; even that of the precursors (indole-3-pyruvic acid and indole-3-acetonitrile) distinctly increased. After this rapid rise, a definite decrease in the concentration of both indole-3-acetic acid and its precursors was observed. The concentration of these substances in the spontaneously sprouting tubers increased more slowly. The level of the free auxins, however, rose gradually even after sprouting.

The treatment with 'Rindite' considerably accelerated the disappearance of the inhibitors. While in the control tubers the inhibitors disappeared only in about 30 days, in the treated tubers they disappeared in five days. These results are in agreement with Hemberg's[5] data.

On the chromatograms of the non-acid fractions the presence was noted of a growth-promoting substance (R_F 0·55) identified as indole-3-acetaldehyde. Its concentration in the treated tubers also rapidly rose until sprouting, then it dropped to the initial level. In the controls, however, no diminished concentration was observed after sprouting. The presence of indole-3-acetonitrile (R_F 0·87) was noted also in the non-acid fractions. Inhibitors in the non-acid fractions have been found only in traces. In the tubers treated with 'Rindite' when sprouted another non-acid growth-promoting substance appeared with about 0·8 R_F value. No such substance was found in the controls.

Details will be dealt with in another publication.

Preparation of Copepod Mounts for Taxonomic Work and for Permanent Collections

DURING an investigation of the microfauna of the shore at Whitstable, Kent, it was necessary to examine and to identify the many Harpacticoid copepods which occurred there. At the same time it was desirable to build up a type collection of these animals.

For purposes of identification one must be able to examine both dorsal and ventral aspects of these copepods at high magnifications. Hence preparations should be mounted on rectangular cover-glasses rather than on conventional microscope slides so that they may be equally accessible to study when inverted. In my experience, the following technique has proved satisfactory. The copepod is placed on a 2 in. × $\frac{7}{8}$ in. No. 1 cover-glass and killed with hot 70 per cent alcohol. Traces of salt are removed by flushing with cold 70 per cent alcohol, and the alcohol afterwards removed by filter paper. Polyvinyl lactophenol, with chlorazol black in solution, is now applied to the specimen, which is then covered with a ½-in. diameter No. 0 cover-glass: by moving the top cover-glass with a fine mounted needle the animal may be correctly orientated.

Since the taxonomy of the Harpacticoid copepods largely rests on limb bristle characters it is essential that these bristles be well stained and clearly visible. By virtue of its permanence, chlorazol black has proved superior to lignin pink and cotton blue as a copepod stain in lactophenol preparations.

Demonstration of Small-scale Water-currents by means of Milk

SMALL particles of relatively inert materials such as carmine, graphite, clay and starch are often used for showing up the currents of water produced by the feeding, swimming and other movements of small aquatic animals. Although such particles may be satisfactory for showing ciliary activity, when mucus is almost always present, in other cases they tend to disperse and sink, and are difficult to photograph. During work on the behaviour of barnacles we found that ordinary cow's milk offers a better means of detecting and measuring small water-currents, and is superior to artificial emulsions. We have since learned that milk has been used for showing the behaviour of aircraft models in a water-tunnel[1]. It seems possible, therefore, that the method may be of general use.

In our technique the animals are placed in a small vessel of still water and observed or photographed against a black background. The milk is injected into the water above the animal from a row of fine jets (Fig. 1, *A*) connected to a syringe. The syringe is operated manually by means of a screwed thread and knob, allowing the milk to be injected either in a steady stream or in blobs. The density can be adjusted by dilution with the medium or by varying the cream content. Normally the milk tends to clot slightly at the interface with sea water, and remains suspended as a trail, resembling thick smoke in air. The milk does not seem to have any harmful effect on marine animals; indeed, barnacles accept it as food, although if large quantities are administered it is found apparently unchanged in the fæcal pellets.

This method has enabled us not only to measure the external water currents set up by barnacle cirri, but also to establish the presence of an internal water-current passing through the mantle cavity during normal beating. The mantle current enters at the carinal end of the aperture near the mouth (Fig. 1, *B* and *C*), passes the filter net formed by the smaller cirri and mouth parts[2], flows around the branchiæ and is ejected as a strong jet between the prosoma and rostrum on the downward beat of the cirri (Fig. 1, *D*). A circulation of this type seems universal in cirripedes, and has been demonstrated in the following species: *Verruca stroemia* (O. F. Müller), *Chthamalus stellatus* (Poli), *Balanus amphitrite* (Darwin), *B. balanoides* (L.), *B. crenatus* Bruguière, *B. hameri* Ascanius, *B. improvisus* Darwin, *B. perforatus* Bruguière, *B. porcatus* da Costa, *B. spongicola* Brown, *Elminius modestus* (Darwin), *Acasta spongites* (Darwin), *Pyrgoma anglicum* Leach, *Hexelasma hirsutum* Hoek, *Alcippe lampas* Hancock.

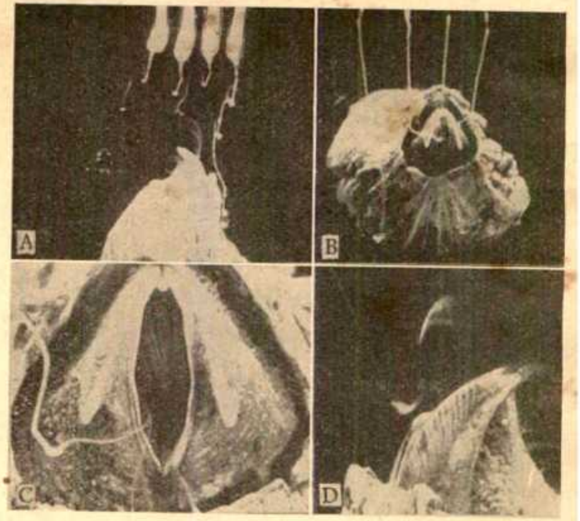

Fig. 1. *Balanus porcatus*: *A*, Side view with cirri extended showing displacement of all milk trails; *B*, top view with valves beginning to open, showing three trails drawn into mantle cavity; *C*, close-up of *B* with single trail; *D*, side view in close-up during downward beat of cirri, exhalant current indicated by upward loop in milk trail. (All enlarged from 16 mm. reversal film)

The mantle circulation depends on the movement of the prosoma and valves, and can be maintained when the movement of the larger cirri is scarcely noticeable; conversely, it is reduced during particularly active movements of the cirri.

These investigations will be published in detail elsewhere. In the meantime a ciné film demonstrating the milk technique, together with other aspects of the behaviour of barnacles, is available.

Letters of J. Purkyně

HAVING recently completed an edition of the complete works of J. Purkyně, I am preparing to publish his letters. In this connexion I am seeking especially letters which he wrote to the British physiologist, Martin Barry (1802–55), and also any letters which show Purkyně's relations with the Royal Society. I should be grateful if anybody possessing letters by or concerning Purkyně, or anybody knowing of their whereabouts, would write to me.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Sunday, November 11

British Broadcasting Corporation (Home Service), at 9.15 p.m. —Sir Edward Appleton, F.R.S.: "Science and the Nation". (First of six Reith Lectures. Further lectures on November 18, 25, December 2, 9 and 16.)

Monday, November 12

British Occupational Hygiene Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 10.30 a.m.—Conference on "Fires in Industry".

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. W. Ross Ashby: "Basic Strategies of Research in Biological Systems".

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. H. Grüneberg: "Genes in Mammalian Development".*

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. F. Bergel: "The Study of Biologically Active Agents as a Vocation" (Jubilee Memorial Lecture).

Royal Institute of Chemistry (joint meeting with the Woolwich Polytechnic Scientific Society at the Woolwich Polytechnic, London, S.E.18), at 7.30 p.m—Prof. R. L. Wain: "Plant Growth-Regulating Substances".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Lieut.-Cmdr. M. J. N. Foster, R.N.: "Operation 'Deepfreeze 1' ".

Tuesday, November 13

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, London, S.W.1), at 4.30 p.m.—Papers on "Research in Automobile Stability and Control".

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Prof. L. F. Wiggins: "Chemistry and the Sugar Cane".

Institution of British Agricultural Engineers (at 6 Buckingham Gate, London, S.W.1), at 5.30 p.m—Dr. P. Payne: "The Mechanical Properties of Soil in Relation to Basic Cultivation".

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. L. Barden and Mr. P. C. G. Isaac: "The Effect of Synthetic Detergents on the Biological Oxidation of Sewage".

Society of Chemical Industry, Chemical Engineering Group (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Mr. H. L. Riley: "The Manufacture of Phthalic Anhydride by the Fluidized Catalyst Method".

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W.C.2), at 6.30 p.m.—Dr. M. V. Wilkes: "Digital Computers and how they may help the Engineer" (The Students' Lecture).

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Dr. E. W. Still: "Air Conditioning of Aircraft".

Wednesday, November 14

Physical Society, Colour Group (in the Lecture Theatre of the Institute of Ophthalmology, Judd Street, London, W.C.1), at 3.30 p.m. —Mr. D. L. Simms: "Colour in Fire Research".

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. J. A. H. Lee: "Some Problems raised by the Regional Variations in Intellectual Ability in Britain".*

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Scientific Papers.

University of London (at the School of Pharmacy, 17 Bloomsbury Square, London, W.C.1), at 5.30 p.m.—Brigadier-General Sir Harold Hartley, F.R.S.: "The Contributions of Pharmacy and Chemical Engineering to World Needs".* (Further lecture on November 15.)

Manchester Literary and Philosophical Society, Social Philosophy Section (in the Reynolds Hall, College of Technology, Manchester), at 5.45 p.m.—Prof. T. E. Chester: "Some of the Human Problems Present in Modern Industrial Society".

Royal Institute of Chemistry (at the Iron and Steel Institute, Grosvenor Gardens, London, S.W.1), at 6.30 p.m.—Annual General Meeting.

Society for Analytical Chemistry, Biological Methods Group (at "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m. —Discussion Meeting on "Biological Methods in the General Analytical Laboratory".

Thursday, November 15

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. A. V. Hill, F.R.S.: "The Effect of Potassium on the Resting Metabolism of the Frog's Sartorius"; Mr. G. A. Horridge: "The Co-ordination of the Protective Retraction of Coral Polyps".

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. Edward Rich: "A New Process for Pneumatic Stowing: Its Development and Introduction at the Rio Tinto Mines, Spain"; Mr. M. R. Goldick: "Some Developments in Tailing Disposal at Roan Antelope Copper Mines, Northern Rhodesia".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—The Fisheries Laboratory, Lowestoft. Papers by Mr P. M. J. Woodhead, Mr. A. D. Woodhead and Mr. J. E. Shelbourne.

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Annual General Meeting. Sir Geoffrey Taylor, F.R.S.: "Some Simple Problems in Fluid Dynamics".

University of London (at King's College, Strand, London, W.C.2), at 5 p.m.—Dr. Grey Walter: "The Electrical Activity of the Brain".*

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. Dorothy Needham: "The Biochemistry of Muscular Action".* (Further lecture on November 22.)

University of London, Institute of Education (at Goldsmiths' College, New Cross, London, S.E.14), at 5 p.m.—Prof. J. A. Lauwerys: "Education for Social Progress in Under-developed Countries".*

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. W. H. J. Vernon: "Metallic Corrosion and Conservation". (Fourth of a series of six lectures on "The Conservation of Natural Resources".)

Physical Society, Acoustics Group (at the Institute of Laryngology and Otology, Grays Inn Road, London, W.C.1), at 5.30 p.m.—Miss P. H. Strange: "Sensations of Pitch".

Society of Chemical Industry, Agriculture and Microbiology Groups (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Meeting on "Recent Developments in Virus Research". Mr. F. C. Bawden, F.R.S.: "Plant Virus Diseases"; Dr. Kenneth M. Smith, F.R.S.: "Viruses Attacking Insects".

Institution of Mechanical Engineers, Internal Combustion Engine Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "Are Diesel Engines an Interim Phase in Rail and Road Transport Development?"

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Reading of Original Papers to commemorate the 70th Birthday of Sir Ian Heilbron, F.R.S.

Thursday, November 15—Friday, November 16

Institute of Physics and The London and Home Counties Regional Advisory Council for Higher Technological Education (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2)—Joint Conference on "Degree and Diploma Courses in Applied Physics".

Friday, November 16

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion on "Bombardment of the Earth by Meteors and Meteorites". Speakers: Prof. H. Bondi (who will read a contribution sent by Mr. T. Gold), Dr. J. G. Davies and Dr. M. H. Hey.

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5.15 p.m.—Mr. J. E. D. Williams: "Navigational Aspects of Turbo-Prop Operations over the North Atlantic".

Royal Meteorological Society (in the Conference Hall, County Hall, London, S.E.1), at 5.30 p.m.—Mr. N. Bradbury: "Aviation Meteorology"* (Lecture for Sixth-form Scholars).

Institution of Mechanical Engineers, Applied Mechanics and Lubrication Groups (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Dr. A. W. Crook: "Simulated Gear Tooth Contacts—Some Experiments upon their Lubrication and Subsurface Deformations".

Institution of Chemical Engineers, Graduates and Students Section (at Caxton Hall, Westminster, London, S.W.1), at 6.30 p.m. —Mr. G. A. Dummett. "Research and Development in a Chemical-Plant Manufacturing Firm".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Sir Charles Dodds, F.R.S.: "Pharmaceutical Applications of Modern Biochemistry".* (Sixth of ten University Extension Lectures on "Technology and Industry". Further lectures on November 23, 30, December 7 and 14.)

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. I. A. Richmond: "Roman Military Engineering".

Saturday, November 17

Biochemical Society (at the Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E.5), at 2 p.m.—Scientific Papers.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Biochemist, Senior grade (with a first- or second-class honours degree), in the Pathological Department, for duties which include both routine hospital biochemistry and work connected with the investigations into the uses of radioactive isotopes in medicine—The Secretary, Liverpool Radium Institute Management Committee, 1 Myrtle Street, Liverpool 7 (November 17).

Lecturer (with a good honours degree, and preferably a teaching diploma and experience) in Physics at the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 1 Woburn Square, London, W.C.1 (November 20).

Chemist (Metallurgist) (with an honours degree in metallurgy, chemistry or chemical engineering, or Associate of the Royal Institute of Chemists or Institution of Metallurgy, or equivalent qualifications) at the Ministry of Supply Royal Ordnance Factory, Birtley, Co. Durham, for research and development work in connexion with new manufacturing processes, the control of laboratory staff, and the preparation of reports for publication—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.740/6A (November 23).

Assistant Lecturer (preferably with a special interest in petrology) in Geology—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (November 26).

Research Officer (honours graduate in agricultural science and satisfactory postgraduate experience in crop and grassland husbandry) in the Department of Agriculture's Peatland Experimental Station at Glenamoy, Co. Mayo—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (November 27).

Assistant Principal of the Wright–Fleming Institute of Microbiology—The Secretary, Wright-Fleming Institute, St. Mary's Hospital Medical School, Paddington, London, W.2 (November 30)

Chair of Anthropology in the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 30).

Lecturer in Agricultural Zoology at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 30).

Physicists or Engineers (university graduates with basic training in physics or engineering including an honours degree, and evidence of research experience and ability) in the Wool Textile Research Laboratory, Commonwealth Scientific and Industrial Research Organization, Geelong, to take charge and assist with new projects—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2 (November 30).

Scientific Officer (over 24, with an honours degree in zoology or botany (preferably with qualifications in both), or agriculture or forestry or equivalent, and a special interest in some branch of natural history), for conservation and regional work in South Wales—The Establishment Officer, The Nature Conservancy, 19 Belgrave Square, London, S.W.1 (November 30).

Senior Research Assistant or Research Assistant, for research on the electrochemistry of salts of low melting points—Prof. A. R. Ubbelohde, F.R.S., Chemical Engineering Department, Imperial College, London, S.W.7 (November 30).

Lecturer or Assistant Lecturer in Applied Mathematics—The Registrar, The University, Sheffield (December 1).

Lecturer or Assistant Lecturer in the Department of Geology—The Secretary and Registrar, The University, Southampton (December 5).

Lecturer or Assistant Lecturer in Gas Engineering, and a Lecturer or Assistant Lecturer in General Fuel Science—The Registrar, The University, Leeds (December 10).

Chair of Extraction Metallurgy in the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (December 12).

Lecturer (with special qualifications and experience in human geography) in Geography; and a Lecturer (with an honours degree or higher in psychology) in Psychology at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Tasmania, December 15).

Reader in Physics at the University of Sydney, Australia, to assist the Professor in the direction of a laboratory concentrating on problems in high energy nuclear physics using cosmic rays and accelerators—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 15).

Senior Lecturer or Reader in Protein Chemistry, and a Lecturer (with research experience in biochemistry or organic chemistry, preferably, but not essentially with plant material) in Agricultural Biochemistry at the Waite Agricultural Research Institute—The Registrar, University of Adelaide, Adelaide, South Australia (December 15).

Chair of Biochemistry in the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 31).

Senior Lecturer or Lecturer (Grade I or Grade II) in Tropical Agriculture, at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 31).

Agricultural Librarian (with a university degree in agricultural economics, agriculture or biological science, and some experience of technical library work, especially abstracting) in the Department of Agriculture, Western Region, Nigeria, to take charge of the Departmental Technical Library, to make abstracts and prepare symposium for the use of Technical Officers, and to assist with the preparation of articles for publication, etc.—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/410/019.

Assistant Librarian at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Assistant Teacher, Grade B, in Physiology and Pharmacology, in the Department of Pharmacy, College of Technology, Liverpool—The Director of Education, 14 Sir Thomas Street, Liverpool 1.

Curator/Technician (preferably with special interests in palæontology) in the Department of Geology, for duties which will include the care and cataloguing of geological laboratory and museum specimens and collections—The Registrar, University College, Singleton Park, Swansea.

Fisheries Officer (Fish Culture Research) (with an honours degree in biology with emphasis on zoology; appropriate knowledge of chemistry and statistical methods; ability to read French and possibly German, and preferably experience of similar or related work) with the Federation of Nigeria, to undertake research into the pond culture of local species of fish and into the chemistry and plankton populations of fish ponds to ensure the most profitable use of available nutrients, food-stuffs and fertilizers—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.65/14/01.

Lecturer (with a university degree, and preferably a qualification in engineering, and some experience in industry and teaching) in Mathematics—The Registrar, Loughborough College of Technology, Loughborough.

Physicist, Senior grade (with a knowledge of X-rays, radium and radioactive isotopes), in the Radiotherapy Department, for duties which concern routine radiotherapy physics, and the applications of radioactive substances in other branches of medicine—The Secretary to the Board of Governors, Charing Cross Hospital, London, W.C.2.

Plant Pathologist (with an honours degree in botany, or natural science including botany) in the Department of Agriculture, Kenya, to assist in producing new varieties of wheat and other cereals resistant to the increasing number of rust strains—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/7/030

Principal/Senior Scientific Officer (with a first- or second-class honours degree in physical or inorganic chemistry, and experienced physical chemist with a special interest in thermodynamics) to assist in the direction and carrying out of research on a variety of subjects—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 1311/34.

Reader, Senior Lecturer or Lecturer in (*a*) Inorganic Chemistry and (*b*) Physical Chemistry at the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Senior Technician (with F.I.M.L.T. or equivalent qualification, and experience in hospital biochemistry) in the Department of Chemical Pathology—The Secretary, Guy's Hospital Medical School, London, S.E.1.

Statistician/Physicist (preferably with a university degree or at least H.S.C. in science subjects or G.C.E. (advanced level) in two science subjects, or equivalent qualifications, and relevant experience), in the Electronics Division, for work associated with nucleonic instrumentation reliability studies—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting Ref. 611/34.

PERMUTIT ION EXCHANGE MATERIALS

The use of Permutit Ion Exchange Materials in many roles distinct from water treatment, has resulted in the development of numerous new industrial processes giving improved results and lower running costs. Some materials now available are :—

Zeo-Karb Na. A sulphonated coal product containing both strong and weak acid groups.

Zeo-Karb 215. A nuclear sulphonated phenol resin containing also hydroxyl groups.

Zeo-Karb 225. A unifunctional cross linked sulphonated polystyrene resin in bead form of high capacity and exceptional chemical and physical stability.

Zeo-Karb 226. A unifunctional cross linked methacrylic acid resin in bead form containing only carboxyl groups as the ion active groups.

De-Acidite E. A high capacity anion exchange material of medium basicity.

De-Acidite FF. A unifunctional very highly basic anion exchange resin in bead form based on cross linked polystyrene and containing quaternary ammonium groups.

De-Acidite G. A unifunctional weakly basic anion exchange resin in bead form based on cross linked polystyrene and containing diethylamino groups.

De-Acidite H. A material similar to "De-Acidite G" but containing dimethylamino groups.

Bio-Deminrolit. A mixed cation and anion exchange resin for demineralisation in a single column.

Decalso F. A synthetic sodium aluminium silicate suitable for the separation and concentration of vitamins and hormones

Decolorite-Asmit. A resin of high porosity for removing colour from solutions.

Permaplex C-10. A highly selective cation exchange resin membrane containing SO_3H groups.

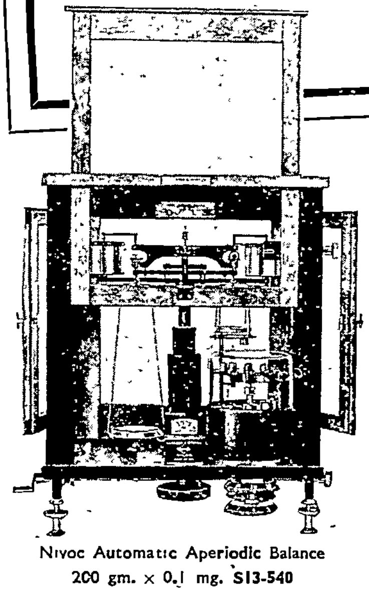
Permaplex A-10. A highly selective anion exchange resin membrane containing quaternary ammonium groups.

For full technical information please write to: THE PERMUTIT COMPANY LIMITED. Head Office and Laboratories: Dept. V.H.92, Permutit House, Gunnersbury Avenue, London, W.4. Telephone: CHIswick 6431

Permutit Ion Exchange Materials—Made in Britain by British Labour

300 mg. is the smallest weight required to obtain a final reading of 0·1 mg.

Usually only two, but at the most three weights plus the two ring weights are all that are required for each weighing.



Nivoc Automatic Aperiodic Balance
200 gm. × 0.1 mg. S13-540

NIVOC APERIODIC BALANCES

Patented in Great Britain (622271 and 622227) and other countries.

Outstanding Features of the Automatic Aperiodic Balance are:

The weights are adjusted to 0.1 mg., therefore weight errors are negligible.
Aperiodicity 7 seconds unloaded, 14 seconds with capacity load.
The weights are contained in a dustproof, glass topped housing within the balance case providing additional safeguard against corrosion.
Weights are automatically centred on the "Stools".
It is impossible to apply weights while the beam is swinging.
All weights are applied mechanically.
A Patented device ensures exceedingly smooth contact between knife edges and planes, reducing wear to a minimum.

WE WOULD ALSO COMMEND

- The Nivoc Aperiodic Balance, 200 gm. × 0.1 mg. S13-500
- The Nivoc Semi-Micro Aperiodic Balance, 50 gm. × 0.01 mg S13-700

GRIFFIN & GEORGE LIMITED

HEAD OFFICE, EALING ROAD, ALPERTON, WEMBLEY, MIDDX. PERivale 3344

LECTURES AND COURSES

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

LONDON, S.W.7

TECHNICAL OPTICS SECTION

A course of six lectures on "Microwave Optics" will be given by Dr. J. Brown (University College, London) on Tuesdays and Thursdays at 4.30 p.m., commencing Tuesday, November 27, 1956, but omitting November 29. The lectures will be held in the Physics Department, Royal College of Science, Imperial Institute Road, South Kensington. The fee for the course is £2 2s. Students of the College and Inter-Collegiate students will be admitted free.

Copies of the syllabus and application forms may be obtained from the Registrar of the Imperial College, Prince Consort Road, S.W.7.

RADIOISOTOPES AND THEIR USES

Full-time courses, each of four weeks' duration, on the use of radioisotopes will be held in the Department of Chemistry.

SIR JOHN CASS COLLEGE
JEWRY STREET, LONDON, E.C.3

beginning on Monday, January 14, 1957.

The courses will be largely practical in content and will be suitable for persons of graduate standing. Places are strictly limited. Fee, £30

Further particulars and application forms may be obtained from the Secretary at the College.

OFFICIAL APPOINTMENTS

UNIVERSITY OF LONDON

GENERAL CERTIFICATE OF EDUCATION EXAMINATION

The Senate invites applications for appointment as Chief Examiners at the General Certificate of Education Examination in the year 1958 in the following subjects: Advanced and Scholarship Levels:—Art, Botany, British Constitution, Chemistry, Economics, French, Geography, Mathematics, Physics, Spanish, Zoology. Ordinary Level: Art, Biology, Cookery, English Economic History, English Language, French, General Science, Geometrical and Mechanical Drawing, Classical Hebrew, Human Anatomy Physiology and Hygiene, Latin, Logic, Pure Mathematics, Pure Mathematics (Statistics), Additional Pure Mathematics, Physics. Applications are also invited for appointment as Assistant Examiners at both Advanced and Ordinary Levels in Botany, British Constitution, Economics, English Economic History, History, Latin, Physics, Religious Knowledge, Zoology.

Application forms and particulars of remuneration and duties are obtainable from the Secretary to the University Entrance and School Examinations Council, University of London, The Senate House, London, W.C.1, to whom applications must be returned not later than December 14, 1956. The Senate desires that no application of any kind be made to individual members.

D. W. LOGAN,
Principal.

LIVERPOOL RADIUM INSTITUTE MANAGEMENT COMMITTEE

1 MYRTLE STREET, LIVERPOOL, 7

Applications are invited for the post of Biochemist (Senior Grade) in the Pathological Department of the Institute. First- or second-class honours degree essential. The appointment includes both routine hospital biochemistry and work connected with the investigations into the uses of radioactive isotopes in medicine. Ample opportunity and facilities are available for work of a research nature into the problems of the biochemistry of neoplastic disease. Salary and conditions of service in accordance with the recommendations of the Whitley Council.

Applications, stating age, qualifications and experience, together with the names and addresses of two referees, to reach the Secretary by November 17, 1956.

KENT EDUCATION COMMITTEE

MEDWAY COLLEGE OF TECHNOLOGY

Applications are invited from suitably qualified persons for the post of Assistant, Grade B, in Botany. Knowledge of zoology would be an added qualification.

Application forms and further particulars can be obtained from the Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham.

PHYSICAL AND INORGANIC CHEMISTS

required by

THE ATOMIC WEAPONS RESEARCH ESTABLISHMENT, ALDERMASTON, BERKSHIRE.

in the grades of Experimental Officer/Assistant Experimental Officer to engage in research on a variety of interesting and novel projects which include the chemistry related to reactors and the chemistry of inorganic and organic phosphors.

The minimum qualification is H.S.C. (Science), Inter B.Sc. or equivalent but possession of H.N.C. (Chemistry) or a general degree would be an advantage.

Salary: Experimental Officer, £940 to £1,155 per annum; Assistant Experimental Officer, £375 (at age 18) to £495 (at age 21) to £815 per annum. At present the rates for women are slightly lower.

Contributory superannuation scheme. A house or assistance towards legal expenses on house purchase will be available for married officers living beyond daily travelling distance.

Requests for application forms, by postcard, to Senior Recruitment Officer at above address. Please quote ref. 1314/34.

MAURITIUS SUGAR INDUSTRY RESEARCH INSTITUTE

Applications are invited for the post of Entomologist. Candidates must have obtained an honours degree in zoology with training in entomology. Experience in the control of insect pests occurring in the tropics especially those attacking sugar cane is desirable. Terms of appointment: On agreement for three years in the first instance with prospects of permanent employment thereafter. Salary according to qualifications and experience in the range Rs.18,000 to Rs.24,000 per annum (£1,350 to £1,800 approximately). Compulsory pension contribution of 5 per cent of salary to the Mauritius Sugar Industry Pension Fund. Free passages on appointment and leave, for officer, wife and children up to a maximum cost of three adult passages. Six months' vacation leave after three years' service. Applications with proof of professional qualifications and the names and addresses of two referees must be sent by registered airmail to the Director, Mauritius Sugar Industry Research Institute, Reduit, Mauritius, so as to reach the addressee before January 17, 1957.

ST. MARY'S HOSPITAL MEDICAL SCHOOL

NICHOLAS FELLOWSHIP

Research Fellow required for an initial period of three years to investigate certain pharmacological or biochemical aspects of cardio-vascular disease. Medical qualification not essential. Salary £1,000 per annum.

Applications, together with the names of two referees, to the Secretary, St. Mary's Hospital Medical School, Paddington, W.2, by November 30, 1956.

H.M. OVERSEA CIVIL SERVICE

WESTERN REGION OF NIGERIA

Entomologist required in the Medical Department to advise on and supervise mosquito control measures in towns and rural areas in the Region, and carry out surveys on distribution and epidemiological importance of other insect vectors of disease. He will be required to tour extensively and spend considerable portion of his time living under field conditions. Honours degree in natural science and specialized training and experience in entomology required Experience in mosquito control work desirable. Appointment on short term contract with gratuity payable on satisfactory completion of engagement. Salary from £870 to £1,824 (starting point determined by age and experience). Gratuity of £37 10s. for each completed three months service (including leave). Male officers receive supplementary pay of £120 a year. Quarters provided at low rental. Taxes at local rates. Annual local leave permissible; generous home leave granted after each tour of 18 to 24 months. Free return passages for officer, wife and children (up to three).

Application forms from Director of Recruitment, Colonial Office, London, S.W.1 (quoting BCD.117/410/07).

UNIVERSITY OF KHARTOUM

Applications are invited for (1) Readershi (2), Senior Lectureship or (3) Lectureship in (Inorganic Chemistry, (b) Physical Chemistr Salaries (1) £E.2,175 per annum, (2) £E.1,602 b £E.75 to £E.1977 per annum, (3) £E.1,152 b £E.75 to £E.1,677 per annum. Entry point to (according to qualifications and experience. Co of living allowance approximately £E.120 p annum. Outfit allowance £E.50. Family allow ances: wife, £E.60 per annum; first child, £E.9 per annum; second and third child, £E.30 p annum. Passages for appointee and family o appointment, termination and annual leave. Ap pointments on contract for five years with poss bility of renewal. Superannuation scheme.

Applications (eight copies), detailing qualific tions and experience and naming three referee to be received as soon as possible by Secretar Inter-University Council for Higher Educatio Overseas, 29 Woburn Square, London, W.C. from whom further particulars may be obtained.

IMPERIAL COLLEGE OF TROPICAL AGRICULTURE

TRINIDAD, B.W.I.

Principal and Director of Research: G. A. C Herklots.

DEPARTMENT OF SUGAR CHEMISTRY AN TECHNOLOGY

Applications are invited for the post of Directo of Sugar Research, under the B.W.I. Sugar Re search Scheme, which became vacant in Octob due to the resignation of Dr. L. F. Wiggin Ph.D., D.Sc., F.R.I.C. Applicants must posse a good honours degree and considerable researc experience in physical or organic chemistry or technology which would enable them to dire a team of research workers and to take part i and supervise diploma courses in sugar technolog Applications from experienced chemical engi eers would also be acceptable. The salary woul be in the Senior Principal Scientific Officer sca which with allowances range from £2,050 t £2,300. An additional payment would be con sidered for an especially well qualified candidat

Applications should be submitted by Janua 15, 1957, to the Secretary, The Imperial Colleg of Tropical Agriculture, 40 Norfolk Stree London, W.C.2, from whom further particula are obtainable.

UNIVERSITY OF LEEDS

DEPARTMENT OF GAS ENGINEERING AN GENERAL FUEL SCIENCE WITH CERAMIC

Applications are invited for two posts of Le turer or Assistant Lecturer, one in Gas Enginee ing and one in General Fuel Science, at salari on the scale £650 by £50 to £1,350 a year for Lecturer or within the range £550 to £650 a ye for an Assistant Lecturer, according to age, qua fications and experience.

Applications (three copies), stating date of birt qualifications and experience, together with t names of three referees, should reach the Reg trar, The University, Leeds, 2 (from whom furth particulars may be obtained), not later tha December 10, 1956.

CITY OF LEICESTER EDUCATIO COMMITTEE

COLLEGE OF TECHNOLOGY AND COMMERCE

Principal: R. E. Wood, M.Sc., F.Inst.P.

Applications are invited for the post of fu time teacher in Physiology in the Department Biology Applicants must possess a good degr in physiology, preferably also with experience pharmacology and must be prepared to take pa in teaching these subjects to Part 2 B.Phar standard. Salary: Burnham Scale for Grade Assistants; for a graduate in the range £725 £1,225 per annum according to qualificatio teaching, and approved industrial experience.

Forms of application, to be returned as soon possible, and further particulars may be obtain from the Registrar, College of Technology a Commerce, The Newarke, Leicester.

ELFED THOMAS,
Director of Educatio

UNIVERSITY OF BRISTOL

Applications are invited for the appointment an Assistant Lecturer in Veterinary Medicin Grade III. Salary scale £550 by £20 to £600 for special qualifications or experience £600 £25 to £650.

Further particulars may be obtained from t undersigned, with whom applications, includi the names of two referees, should be lodged n later than December 1, 1956.

H. C. BUTTERFIELD,
Registrar and Secretary

DEVELOPMENT OF THE PEACEFUL USES OF ATOMIC ENERGY

T is not without significance that the opening by the Queen of Britain's first nuclear power station as almost coincided with the approval by a con-rence of eighty-two nations of the draft statute for e International Atomic Energy Agency and the lection of a preparatory commission of eighteen ountries with the task of bringing the Agency into eing. This preparatory commission is expected to eet, probably in Europe, early next year, and it is oped the International Agency, the headquarters of hich are to be in Vienna, will come into being by e end of 1957. The Commission will consist of ustralia, Belgium, Brazil, Britain, Canada, Czecho-ovakia, France, India, Portugal, South Africa, the S.S.R. and the United States, together with rgentina, Japan, Egypt, Peru, Indonesia and akistan, elected on October 23; and the draft atute now approved empowers the board of overnors of the Agency to send inspectors into ecipient countries to ensure that neither fissionable materials supplied to such countries nor the by-roducts of such materials are used for military urposes. The Agency is also empowered to require e recipient countries either to apply such by-roducts to peaceful purposes or re-deposit them ith the International Atomic Energy Agency.

This compromise was adopted after the United tates and India had withdrawn conflicting proposals r inspection. The former had sought to ensure that l by-products of fissionable materials furnished by e Agency should be open to complete inspection, hile the latter held that such controls were too weeping and would interfere with the internal conomy of recipient countries. In its amended rm, this controversial Article 12 is intended to revent building up of stocks of by-products for urposes not approved by the Agency, and while r Alec Randall, speaking on behalf of Australia, anada, New Zealand and South Africa as well as ritain, could with justice claim that the agreement ached on the safeguarding provisions is a happy gury for the future of the Agency, it remains to be en how far in practice the sensitive nationalism of astern countries, and especially the under-developed untries, will accept the restraints on sovereignty at are inescapable in any effective scheme of ternational co-operation.

What is most important at the moment is that e way is now open for world co-operation in the se of nuclear energy for constructive purposes on e lines first suggested by President Eisenhower in s message to the United Nations in December 1953. hen all allowance is made for the stimulus provided y the conference at Geneva in August 1955, much the credit for the success of this, the most repre-ntative international conference ever held, must be ven to its president, Señor Muniz, of Brazil, whose ilful guidance contributed largely to overcoming litical obstacles and reconciling conflicting views. ne way to co-operation is clear at the very moment hen the opening of the Calder Hall nuclear power station in Britain has given emphatic demonstration to the world that nuclear power can be generated on the scale on which electricity is normally generated.

Calder Hall is indeed something more than a milestone in the industrial history of Britain. The most impressive fact about Calder Hall is its size—the demonstration that nuclear power has arrived on a big scale and to stay. Mr. R. A. Butler, who deputized at the opening for Lord Salisbury, the Minister responsible for nuclear energy, remarked that the time when no power stations burning coal will be built is much nearer than had previously been thought. He suggested that soon after 1965 all the power stations built in Britain would be nuclear, and that by 1975 the output of electricity from nuclear power stations would exceed and might double that from all the power stations which supply our needs to-day. This means that in twenty years time, nuclear power will be doing the work of more than 40 million tons of coal a year and possibly of 80 million tons, and the theme of his short speech was in fact that nuclear energy has added a new dimension to our natural resources. The Atomic Energy Authority and all those associated with the Calder Hall venture have every right to be proud of an achievement which puts within our reach in the next twenty years something like a 50 per cent increase in the energy resources we at present derive from coal. It represents the culmination of a venture in which calculated risks were boldly and successfully taken, an effective compromise between what is scientifically desirable and what is physically possible with the methods and materials immediately available; and it has put Britain years ahead of the only other two countries yet within striking distance of making commercial amounts of power from uranium.

Sir Edwin Plowden justly remarked at the opening ceremony that we saw in it the birth of a new industry which, if we follow up our first success with vigour and determination, will assure both Britain and the world of a source of power which will be inexhaustible for generations to come. Our more pressing anxieties about the extra coal supplies which increasing productivity demands have been relieved, and while there is no early prospect of a fall in the price of electricity, there is at least a chance that its price may fall relative to the prices of other fuels and industrial materials. It is clear that nuclear generating capacity could easily approach 4 million kilowatts in 1965 and even 5 million kilowatts, or 15 per cent of Britain's generating capacity if all the fifteen stations projected were built. Mr. Butler's statement, in fact, indicates that the Government's programme for nuclear power will be accelerated, and industry has already submitted tenders for reactors of 300,000 kilowatts and could design them for 400,000 kilowatts, or double the capacity for which approval was given in July for the first two nuclear power stations for the Central Electricity Authority, at Bradwell-on-Sea and Berkeley.

It was the Queen herself, however, who emphasized the way in which this demonstration of the possibility of producing industrial power on a large scale from uranium is linked to the work of the international conference which has since met in New York. "Above all," said Her Majesty, "we have something new to offer to the people of the undeveloped and less fortunate areas of the world, who will continue to look to us for assistance and example as they have done in the past. This to me is the real importance of to-day's ceremony."

The urgent need is for some arrangement whereby the technical skill of Britain and those other nations within reasonable distance of producing nuclear power on a commercial scale can be made available to those less fortunate nations ; but it still remains to be seen how widely the new statute will be ratified by governments, and in particular how ready the smaller and undeveloped countries will be to accept the provisions of Article 12 of the statute. It cannot be forgotten that unilateral repudiation of international agreements has seriously damaged the mutual confidence in which alone technical assistance and economic aid from the more advanced to the under-developed countries are possible. The safeguards imposed by that article and the limitations on national sovereignty implied in it have become the more essential and reasonable ; yet at the same time, in many parts of the world where nuclear power offers the greatest possibilities of benefit to human welfare, the growth of nationalism has made those countries more impatient and suspicious of restraint.

The benefits of nuclear energy to mankind will be long postponed, however, unless nations are willing to pay the price and accept those limitations on national sovereignty which are a pre-condition of the co-operation that is needed. In Britain we have still to solve the problem of the right balance of scientific and technical effort between nuclear power development and those other technological developments that are necessary to enable Britain to maintain her place in the world's markets. Sir John Cockcroft last April put the number of scientists and technologists working on nuclear power development as about a thousand ; but the recent report on scientific and engineering man-power in Great Britain gives the number of scientists and engineers employed by the Atomic Energy Authority this spring at nearly 2,500 and forecasts that some 3,200 will be required by 1959—perhaps one-fifth of those already working for the Atomic Energy Commission of the United States.

These figures are not large, in view of the total of 135,000 scientists and engineers estimated as now available in Britain, or 150,000 forecast as required in 1959 ; but they could easily represent an excessive proportion of particular categories of scientists or technologists. Moreover, they do not take account of those engaged on nuclear energy projects outside the Atomic Energy Authority or of those required abroad. It is essential if Britain is to reap the full advantage of the Calder Hall achievement that she should be able to provide other countries with the skilled man-power that they will need unless they are prepared to embark on expensive development work for themselves. As Prof. E. W. Titterton emphasized in his recent book, "Facing the Atomi Future", it is expected that these new developmen will lead to Britain exporting nuclear power station on a large scale, in addition to the export trad already developed in radioactive isotopes and fu filling her traditional role as an exporter of skill. A export trade for the British nuclear energy authorit of at least £300 million by 1975 with a home trad at a similar figure is believed to be possible. Whi the technical aspects of such developments a primarily a matter for the industry itself, the Gover ment should be thinking of the possible repercussior on our economy and our balance of man-power, an of the creation of the conditions most favourable t such an export trade, whether it is to the unde developed areas or elsewhere.

There are two points to be noted here. First, has been suggested that for the present Britain ca best contribute to the development of nuclear energ elsewhere by exporting skill rather than the actu plant—either the full-scale power plant or tl 'package' reactors which are likely to be best suite to the needs of many of the under-developed area This would make smaller demands on our resourc of trained man-power, and it is also an essenti preliminary if many areas lacking indigenous fue and water-power are to operate such plants succes fully. Technical assistance is an essential factor f the full exploitation of the export possibilities, an Mr. Butler's speech at Calder Hall gave perhaps tl first hint that the Government is really alive to the possibilities. The changes in the organization of tl Oversea Civil Service respecting officers with exce tional administrative or professional qualificatio announced in the White Paper last May are a st in the right direction, but something much bold and more imaginative is also required.

The decision as to the proportion of trained ma power and resources Britain can afford to put in the development of nuclear energy may well be o of the most critical that faces the Government in tl immediate future. The establishment of the politic and economic conditions most favourable to such export trade in this field, either through technic assistance or through the new International Atom Energy Agency, is one of its most important politic tasks. The Agency, it should be remembered, is n intended to be a charitable institution, although will be necessary for some means of providing t necessary finance to be found to make possible tl building of nuclear power stations in places whe they are most needed. It cannot yet be said th the under-developed countries—which are usual also impoverished—will accept the safeguards la down in the statute creating the Agency, safeguar which while designed primarily to prevent abuse be closely also on the question of confidence which essential to attract the necessary financial assistanc

If the statement is ratified widely, the Agency m well hasten the day when the under-develop countries will gain some benefit from nuclear energ but international confidence and goodwill must fir be established. Calder Hall should remind us h great is Britain's interest in maintaining peace a in fostering international confidence; and in that respect the Government has its primary responsibility in regard to the new export trade to which we may now look, quite apart from the humanitarian aspect to which the Queen referred. Here it might well be wise for the Government to be more forthcoming in regard to co-operation with the European Atomic Agency, and the fact that agreement has been reached at New York in regard to this vexed question of supervision may perhaps stimulate a fresh effort to deal successfully with that problem in Europe. At least it appears to be more doubtful whether Britain can afford to remain outside, even if to participate fully involves accepting a degree of control over the civil and military uses of nuclear energy which infringes national sovereignty more than we would wish, and, more important, could even impede our internal development and exploitation of nuclear power, as Sir George Thomson notes, at least in respect of the Euratom proposals, in his article on Britain's drive for atomic power in *Foreign Affairs* for October. Risks have to be taken, and Calder Hall is first and foremost the vindication of a policy of calculated risks, imaginatively conceived and boldly taken. The fruits of such an achievement will be reaped in no lesser way. The first task in the present troubled world is the restoration of international confidence. This is principally a duty of statesmen and politicians, though scientists can play their part by demonstrating, as they have already done in organizing the project for the International Geophysical Year, that co-operation is still possible in certain fields of activity among the nations.

CORRESPONDENCE OF LAVOISIER

Oeuvres de Lavoisier

Correspondance. Par René Fric. Fascicule 1: 1763–1769. Pp. xviii+252. (Paris: Éditions Albin Michel, 1955.) 2,750 francs or 8.5 dollars.

THE appearance of the first part of the seventh volume of Lavoisier's collected works marks, we hope, the beginning of the last phase in the publication of the literary remains of this many-sided genius. The first four volumes, containing his contribution to hemistry and physics, appeared during 1862–66 under the editorship of Dumas; Volumes 5 and 6, ontaining his work in geology, meteorology, agriculture, economics and education, were edited by Grimaux during 1894–95; and now comes the beginning of the seventh volume, containing his correspondence between the years 1762 and 1769, ollected and edited with scholarly care by M. René Fric and published under the ægis of the Paris Academy of Sciences, helped by a grant from Unesco.

Lavoisier was born in 1743. His mother died in 748, when his father then went to live with his mother-in-law, and Lavoisier's aunt, Mlle. Punctis, devoted her life to her nephew and his sister. In 760 Lavoisier went to the Mazarin College, where he had distinguished teachers in the sciences, inluding the chemist Rouelle. His interests turned first to geology and for three years he assisted Guettard, the foremost geologist of France, in his researches In 1767 he went on a geological tour in Alsace and Lorraine with Guettard, to collect material for the first geological survey of France. The first half of this volume consists mainly of the correspondence between Lavoisier and his father and aunt during this journey, which lasted four months. They travelled on horseback with an old family servant who carried Lavoisier's barometer and scientific instruments. Lavoisier's letters give a lively description of the incidents of the journey, the progress of his work, and the scientific people they met. The letters from his father and aunt kept him in touch with the life of the family, and reveal their anxiety about the safety of the young traveller and the affectionate home-circle in which they all lived. Travel in France was not without its dangers in those days; but the journey was successful in its object, and Geikie in "The Founders of Geology" speaks of the great promise shown by Lavoisier in his early geological papers.

One of his occupations on the journey was the analysis of the mineral waters in each locality they visited; this and the analysis of minerals first turned Lavoisier's attention to chemistry. His papers were already attracting notice, and the correspondence in 1768 includes letters of congratulation on his election to the Academy at the early age of twenty-five. In the same year Lavoisier joined the Tax Farm, a step which was to have such a tragic ending. The King's Farmers General in France enjoyed the privilege of collecting the indirect taxes on salt and tobacco and certain dues by paying in advance an agreed sum to the Treasury once a year, so that the profitability of their investment depended on the skill of their administration. Lavoisier became an assistant to his future father-in-law, Paulze, and the second half of the volume consists almost entirely of Lavoisier's reports of his work in supervising the collection of the duty on tobacco in the district between Chalons and Lille. The letters describe Lavoisier's daily work and the great care he devoted to his tasks. They show, too, his firm grasp of the administrative problems involved in checking the purchases, the manufacture and the sales of tobacco. Lavoisier makes suggestions for improving the routine of inspection, he sends shrewd comments on the character and ability of the officers, and he devotes much care to the analysis of samples of tobacco to detect adulteration. It was the irony of fate that the chief crime of which he was accused during the Terror was the adulteration of tobacco by increasing its moisture content.

The letters give a revealing picture of Lavoisier as a young man just embarking on his career as a scientist and administrator, and they whet one's appetite for a sight of the next section, which will cover the period when his classic researches on combustion were beginning.

The possibility of continued publication of the remaining volumes must depend partly on the support they receive, and it is to be hoped that nothing will delay their publication. It is confidently expected that the second part of Vol. 1 will appear early in 1957. M. Fric has also traced the missing volume of Lavoisier's laboratory note-books, so that the set is now complete and ready for printing. The extracts published by Berthelot in "La Révolution Chimique" show the intense interest of these daily records of Lavoisier's work. Their publication would throw much fresh light on what was probably the most decisive event in the history of chemistry.

HAROLD HARTLEY

THE ROTHSCHILD COLLECTION OF FLEAS

An Illustrated Catalogue of the Rothschild Collection of Fleas (Siphonaptera) in the British Museum (Natural History)

By G. H. E. Hopkins and Miriam Rothschild. Vol. 2: Coptopsyllidae, Vermipsyllidae, Stephanocircidae, [Macropsyllidae], Ischnopsyllidae, Hypsophthalmidae and Xiphiopsyllidae. Pp. xi+445+32 plates. (London: British Museum (Natural History), 1956.) 6 guineas.

THE first volume of this great work, covering the Pulicoidea, was published in 1953 and a review appeared in *Nature* (173, 1203; 1954). The second volume covers seven (of fifteen) families of the Ceratophylloidea. Most of these families are small, and some may be termed obscure. With one or two exceptions, the families are not especially closely related; their treatment together is therefore largely artificial and has the undesirable feature that their closer relatives will be dealt with sporadically in the remaining volumes of the series. The authors are aware of this defect; but their grouping was dictated by practical considerations. Only three of the families treated are represented in the north temperate parts of the world; of these the Ischnopsyllidae are world-wide in distribution; the Vermipsyllidae, Nearctic and Palæarctic; and the small family Coptopsyllidae, restricted to the Mediterranean and Siberian subregions of the Old World. Xiphiopsyllidae and Hypsophthalmidae are Ethiopian, and Macropsyllidae and Stephanocircidae are Australian, the latter also being well represented in South America. The Coptopsyllidae (one genus and nine species or subspecies) are parasites of gerbilles; the Vermipsyllidae (three and twenty-nine), of ungulates and carnivores; Stephanocircidae (eight and twenty-eight), of marsupials, rodents, and perhaps shrews; Macropsyllidae (two and two), apparently of rodents; Ischnopsyllidae (fifteen and seventy-six), exclusively of bats; Hypsophthalmidae (seven and twenty-six), of rodents and insectivores; and Xiphiopsyllidae (one and four), of rodents.

The introductory sections of the book contain much material that is virtually repeated from Vol. 1. However, these sections, including the phylogenetic 'tree' and lists of genera and subgenera, have been corrected and supplemented to bring them up to date. Much of the glossary of technical terminology is repeated, too; but the definitions and illustrations apply especially to the large superfamily Ceratophylloidea, whereas the glossary of the previous volume emphasized the Pulicoidea. The key to superfamilies, families, and subfamilies of fleas is also repeated, but is provided with illustrations that greatly increase its usefulness.

The general plan of the volume is similar to that of the preceding one; superfamilies, families, subfamilies, and genera are fully defined, but species and subspecies must be determined by use of the keys and illustrations, which are, however, adequate for the purpose. Citations are given for original descriptions and important subsequent publications, and complete records of specimens in the Collection are provided. If satisfactory published illustrations were available, they have been reproduced; in other cases new figures of high quality have been prepared by F. G. A. M. Smit and Arthur Smith. The generosity of the authors and the publishers in the matter of illustrations may be appreciated when one considers that 707 drawings and 193 excellent photographs (mostly by Arthur Barron) are provided to illustrate a volume dealing with only 174 specie and subspecies.

Although primarily a catalogue of the Rothschild flea collection, the finished work will treat all describe species and therefore will virtually constitute a monograph of the fleas of the world. Typographica and other errors in the present volume appear to be few; unfortunately, reference to the Macropsyllida was omitted from the title page. The book is authoritatively written, lavishly illustrated, and beautifully printed and bound. Like its predecessor, it is a credit to the authors and the publishers.

G. P. Holland

THE HOST–PARASITE RELATIONSHIP

Parasites and Parasitism

By Prof. Thomas W. M. Cameron. Pp. xix+322. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1956.) 35*s*. net.

WITH the experience of more than thirty year teaching of parasitology in London, Edinburg and Quebec, Prof. Cameron has written this book which is outstanding for the new approach it make to the subject. It treats parasitism as a natura biological phenomenon and as a branch of ecolog and not from the anthropocentric or economic view point because, all too often in the past, parasitism has had its true nature obscured by a concept o disease and has been regarded subjectively rather tha objectively. It is not a substitute for texts on medica or veterinary parasitology as it deals with principle rather than with practice.

Because of the many unsuccessful attempts tha have been made to formulate an accurate definitio of a parasite, the author attempts to present a concept of the organism by considering how it feed and discusses nutrition and its evolution in an intro ductory chapter. There follows a general survey o parasites in which representative types from th bacteria, fungi, spirochaetes, protozoa, viruse rickettsias, coelenterates, helminths, annelids, arthro pods, molluscs, and vertebrates are discussed. Th is followed by a consideration of the evolution an development of the defence mechanism of the host The consequences of parasitism are then discusse The concluding chapters deal with infectious diseas the factors involved in the distribution of parasite the principles of control of parasites and parasit diseases, host specificity and the evolution of parasite There is a list of 156 selected and annotated reference and a separate list of some important catalogues an indexes. These are followed by a classification of th parasites mentioned in the text and by an adequat glossary and index. Many of the 115 diagram throughout the text are used to replace detaile morphological descriptions which, with systematic have been kept to a minimum mainly for considera tions of space. Misprints and errors are, happil scarce but the following corrections should be noted *Fasciola* metacercaria excysts in the alimentary tra (p. 89), *Polystoma* (p. 98), *Caryophyllaeus* (p. 105 pine-weevil (p. 137) and *Braula* (p. 180).

Prof. Cameron suggests that, to read and unde stand his book, a working knowledge of biology i general is a pre-requisite but not necessarily a knowledge of parasitology. Be that as it may, the reader who already knows something about parasites will get fuller enjoyment from reading this interesting and absorbing account, written in the author's inimitable style, of the various host–parasite relationships. Some parasitologists may not agree with all the author's points of view and may have doubts, misgivings and reservations, which would meet with Prof. Cameron's approval and sympathy, for no one knows better than me how one's personal views depend largely not only upon one's idea of what constitutes parasitism, but also upon one's approach to, and interpretation of, any given 'facts' about parasitic life. J. N. OLDHAM

IONIZED GAS IN PHYSICS AND IN ASTRONOMY

Physics of Fully Ionized Gases

By Lyman Spitzer, Jr. (Interscience Tracts on Physics and Astronomy, No. 3.) Pp. ix+105. (New York: nterscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1956.) Paper, 1.75 dollars; hard cover, 3.50 dollars.

THIS slender volume, the third of a series of "Interscience Tracts on Physics and Astronomy", contains a comprehensive and accurate introduction to the study of physical phenomena exhibited by fully onized gases. Both in electronics and astrophysics the nterest in different manifestations of ionized gases has of late been growing; and its urgency has been nhanced by the fact that the behaviour of such gases s likely to be quite different from that of neutral gas of the ordinary kinetic theory. In point of fact, in certain respects it is likely to be simpler; for most quantum-mechanical effects (except, perhaps, for nteraction with the radiation field) can legitimately be ignored; and, likewise, the encounters between harged particles in ionized gas become simplified owing to the long-range character of the inverse-square forces involved. Although the basic physical principles are thus simpler than in an ordinary gas, the actual motions of gas particles become more complicated; for the ordinary hydrodynamical equations governing their motion must be coupled with Maxwell's equations. In the presence of a magnetic field this coupling gives rise to a whole class of novel phenomena (hydromagnetics); and even in the absence of such fields the electrical properties of onized gas admit of motions which have no parallel n neutral gases.

To which of the two fields of science—physics or astronomy—should the present tract be considered to belong? Its subject has, in recent years, become quite *à la mode* among some astrophysicists, who are apt to regard the more thoroughly studied branches of their cience as 'worked out', and to whom the vistas opening with the combination of hydrodynamical and Maxwell's equations seem to offer an unlimited ground for practising their physical insight or manipulative skill. Yet the fact remains (which is perhaps not made sufficiently clear by the author of the present book) that the connexion between theories of fully onized gases and their experimental verification emains still quite tenuous—both in the laboratory (plasma oscillations) and in the study of certain celestial phenomena (sunspots, or magnetic variable stars being the most conspicuous cosmic examples necessitating hydromagnetic treatment for their understanding). Although some observational data are available on certain aspects of these subjects, their discussion has been entirely excluded from the volume under review, and its contents restricted to those topics which may serve for a theoretical understanding of the subject. This deliberate policy may have helped to keep the size of the book within its modest limits; and a restriction to fundamentals will no doubt extend its useful lifetime.

However, the fact that the gap between theoretical foundations and their possible application to practical cases has been left so wide is probably the most serious criticism of the book which can be raised. Some readers may feel that the book does not bring, at times, its subject sufficiently 'down to earth', and its readability leaves occasionally something to be desired; but its accuracy and reliability as a source of theoretical information should be nowhere in doubt. Like its two predecessors already published in the series of these Interscience Tracts, this present book should thus be viewed primarily as a contribution to physical, rather than astronomical, literature. It should, however, be of interest, not only to research students, to whom it is primarily addressed, but also to all physicists and astronomers interested in a gradual merger of two great physical theories—hydrodynamics and electromagnetism—into a single edifice.

ZDENĚK KOPAL

THE TRANSITION FROM CLASSICAL TO MODERN PHYSICS

Modern Physics

By Prof. John C. Slater. Pp. xi+322. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 39*s*. 6*d*.

THIS book describes the development of theoretical physics during the past sixty years. An introductory chapter on the atom in nineteenth-century physics prepares the ground for a chapter on electron theory and relativity and another one on the beginning of quantum theory. The next five chapters are concerned with the development of the Rutherford–Bohr atom in the period 1912–26. Up to this stage Prof. J. C. Slater uses only elementary mathematics (easy algebra and occasionally calculus). When he comes to deal with the wave-mechanics and its applications, partial differential equations and solutions in terms of Legendre polynomials are used, though he still avoids matrix multiplication and general ideas of operators. The final chapter, on nuclear physics and fundamental particles, is almost entirely non-mathematical and is perhaps the most clearly expressed in the whole book. Rather little space (about ten pages) is devoted to the special theory of relativity. The general theory of relativity and modern field theory are not included. The numerous examples given at the ends of the chapters (with solutions at the end of the book) are of a kind very useful to the student of average ability.

The author says, in the preface, that he wished to write a book which would be suitable not only for the professional physicist but also for "students of history, of human thought and of general culture". He therefore restricted the mathematics "to a rather low level"—which is in fact an impossibly high level for most students of history and general culture. I cannot share the author's belief that the general reader can skip the mathematics and still apprehend the main ideas when so many of the ideas are expressed in mathematical equations. I propose, therefore, to consider the usefulness of this book to physicists and other readers who have some mathematical ability and training.

The teacher of advanced physics to-day never has enough time to deal with all the topics which he feels are important. It is necessary to omit something to make room for new discoveries, and often it is easiest to sacrifice an account of the way in which ideas have developed. The wave-mechanics is presented to the student as a logically complete system—with only a passing reference to earlier theories of atomic physics. Many of the younger university lecturers in physics have been taught in this way, and the sense of continuity with the nineteenth century is lost. Prof. Slater's book is designed to fill this gap, to show how the failures as well as the successes of earlier theories prepared the way for wave-mechanics. His final chapter reveals wave-mechanics apparently completely successful in the world of atoms, molecules and solids and struggling to prepare the way for its successor by its own successes and failures in the world of nuclei and of unstable particles.

The average student for a first degree can with difficulty assimilate the vast meal which is placed before him. It would not be fair to ask him to add this book to his reading list, though an exceptionally good student of this standing might do so. To a graduate who is beginning research or teaching in physics, this book should be very easy reading. It offers him an opportunity to survey his degree course from a new point of view and to learn why and how physical theory has grown into its present form. Those who are old enough to have followed this growth may also be interested to read this systematic account of an exciting period in the history of physical science. R. W. DITCHBURN

WOOD STRUCTURE

The Structure of Wood

By Prof. F. W. Jane. Pp. vii+427. (London: Adam and Charles Black, Ltd., 1956.) 60*s.* net.

ALTHOUGH the average university student of botany devotes no more than a small fraction of his time to the anatomy of the angiosperms and gymnosperms, there has, in recent years, been an increased interest in the study of wood structure. This is because it is being realized more and more that the accurate identification of timbers is impossible without a knowledge of their microscopical structure. For many years the rule-of-thumb methods by which timber merchants were able to recognize the comparatively small number of woods which they normally had to handle, proved adequate for their needs, although mistakes were undoubtedly made. Nowadays, however, with more and more timbers coming into use, especially from parts of the world which were not formerly thought of as timber-producing areas, the task of identification is becoming more difficult. Then again, as Prof. Jane points out in the book under review, although it is still possible to recognize many of the common hardwoods with the aid of a hand lens and a sharp knife, the precise identification of softwoods is well-nigh impossible without resort to the compound microscope. Furthermore, it is impossible to understand the physical and working properties of timber without a knowledge of their structure, while for th study of the molecular structure of the cell walls th electron microscope is now playing its part. For al these reasons there should be a big demand for reliable modern text-book of wood structure such a this one which Prof. Jane has now produced.

The book is written in such a way that it can b used not only by those with an advanced knowledg of plant anatomy, but also by intelligent readers wh can use a microscope and want to learn how to identify timbers, and to know something of the relationships between their properties and structure. It mus have been a difficult problem for the author to decid precisely what aspects of such a wide subject h should deal with in a book of just over four hundre pages; but to the reviewer he appears to have mad a wide and balanced choice of topics. The approac is along traditional lines, for the various types of cell and tissues of which wood is composed are fir described, and it is shown how these are differentiate from the cells of the apical meristem and the cambium and organized in the mature wood. Not only is th structure of ordinary softwoods and hardwood described, but also some attention is devoted t trees and lianes that increase in girth by method which are often thought of as being anomalous, an to the structure of woody monocotyledons, cycad and tree ferns. The chemical nature and sub microscopical structure of wood are considered in chapter written in collaboration with Dr. K. Wilson The last six chapters are concerned with the identification of timbers, not only in a general way; but it also shown, for example, how the various timber that pass in the trade under the names of teak mahogany and walnut may be recognized. Th author also discusses the difficult problem of distinguishing between timbers from closely relate species of a single genus, with special reference t oaks, ashes, elms and maples. The book ends wit an appendix on technique, followed by a selecte bibliography and an index.

The numerous excellent photomicrographs, prepared with the help of Mr. R. Brinsden, add considerably to the value of the book. The autho however, stresses the limitations of photomicrograph as a means of portraying the structure of wood, an rightly emphasizes how line drawings can direc attention to certain diagnostic characters mo effectively. The numerous ingenious diagrams in th text serve to confirm this point of view.

Prof. Jane has provided us with a welcome additio to the literature of wood technology and he ha performed his task very effectively. In readin through the text, however, one cannot fail to no some minor blemishes. For example, it is rath startling to read on p. 32 that a vessel is a conductin "element", and to find on p. 106 the obsolete ter vessel "segment" still in use, while in the last lin on p. 156 there is an incorrect figure reference. would also have been helpful to readers if the rath solid masses of text could have been broken up mo frequently with additional headings and subheading Small defects such as these will, however, no doub be corrected in future editions. It is to be hoped th the book will be used not only by students of woo technology, but also that it may serve to remind students of botany that a good understanding of pla structure lies at the very heart, and not, as so man are apt to believe, at the fringe of their subject.

C. R. METCALFE

ROCK MAGNETISM

At a meeting of Section A of the British Association on September 4, Prof. P. M. S. Blackett opened a discussion on "Rock Magnetism" by giving a brief account of the history and the present state of the subject. He pointed out that although it has been known for the past hundred years that certain rocks, when formed, acquire a weak but definite magnetism in the direction of the Earth's field, it is only recently that this fact has been used for deducing two types of information of the highest scientific importance: first, to trace back for many millions of years the history of the direction and intensity of the geomagnetic field; and secondly, to attempt to settle the old and acute controversy as to whether the continents have always occupied the same positions relative to one another and to the geographical poles.

Discussing the first of these two aspects of palæomagnetism, Prof. Blackett said that his interest in the subject was originally aroused by the work of Johnson, Murphy and Torreson[1] in the United States, who, in 1948, examined the remanent magnetization of a series of varved clays of New England. These clays were laid down in stream beds, and contain small quantities of detrital magnetic material in the form of fine grains, which were oriented along the Earth's magnetic field at the time of deposition. By measuring changes in the direction and intensity of magnetization with depth, over a continuous vertical sequence, it was possible to trace the history of the geomagnetic field over a period extending back to 15,000 B.C. The results showed that during the whole of this time it has undergone regular variations in direction about geographic north. More recent nvestigations have confirmed this view, and it now appears that for at least several million years the main Earth's field has corresponded on the average to that which would be produced by an axial magnetic dipole situated at the centre of the Earth; but that there has been a continuous secular variation about the mean direction, with a time period of 500–1,000 years.

Of the greatest importance was the discovery by Brunhes[2] in 1906 that certain lavas from the Massif Central mountain system in France are magnetized n a direction opposite to that of the Earth's field. Many other examples of reverse magnetization in Tertiary igneous rocks have since been discovered, notably by Bruckshaw and Robertson[3] in Britain, by Roche[4] in France, and by Hospers[5] in Iceland, and more recently by Campbell and Runcorn (unpublished work) in America. All these workers found that while approximately half the rocks sampled had an average palæomagnetic direction corresponding losely to that of an axial dipole, the remaining half were magnetized in the opposite direction. Roche and Hospers, in particular, considered that their findings could be most plausibly interpreted on the assumption that the Earth's main field has reversed periodically during Tertiary and recent times. They suggested that these reversals must have occurred rather suddenly at intervals of the order of a million ears, and that the field intensity in both the opposite irections has been the same. This result, if true, is of extreme importance, and must dominate all future theoretical thinking on the origin of the Earth's magnetism. Many geophysicists, however, regard the hypothesis of the Earth's field reversal with reserve, and Néel[6] has put forward theoretical arguments to show that there are four possible physical mechanisms whereby a rock, in cooling from above its Curie temperature, can acquire a thermo-remanent magnetization in a direction opposite to that of the applied field. The first two of these mechanisms depend on the properties of ferrimagnetic materials, in which the magnetism is associated with two distinct categories of electron, the spins of which are aligned in antiparallel directions. Gorter[7] has recently succeeded in synthesizing a ferrimagnetic material which exhibits magnetic self-reversal in the laboratory, and there is no reason for supposing that such a material may not have been produced naturally in certain rocks. The third and fourth of Néel's mechanisms are based on the supposition that the rock contains two distinct magnetic components with different Curie points, which exist as an intimate mixture of fine grains. When such a rock cools, it is possible in certain circumstances for one component to become magnetized in the reverse field of the other, and for the final direction of magnetization to be opposite to that of the externally applied field. One example of a naturally occurring rock, which exhibits a self-reversing property of this kind in the laboratory, has been found by Nagata[8]. On the other hand, the great majority of reversely magnetized rocks do not exhibit any self-reversing property when tested in the laboratory.

Considering the whole of the evidence at present available, Prof. Blackett thought that while it is very probable that the Earth's field has reversed periodically in the past, this must not be taken as being finally proved.

Turning to the geological aspects of palæomagnetism, Prof. Blackett said that it was realized at least thirty years ago that, by the study of magnetism of rocks, it should be possible to discover whether there has been any relative movement between the continents during past geological ages, as suggested by Wegener[9], du Toit[10] and others. For, by measuring the present direction of magnetization of a system of rocks, it is possible to deduce both the latitude and the orientation relative to the Earth's rotational axis at the time when it was laid down.

The first palæomagnetic evidence of past continental land movement was obtained in 1954 by Clegg, Almond and Stubbs[11], who found rocks of the New Red Sandstone system, over a wide area of England, to be consistently magnetized along a north-east to south-west axis with magnetic dips considerably shallower than that of the present Earth's field. This suggests that England has moved northwards from a position near the equator, and has rotated in a clockwise sense relative to the poles, at some time since the rocks were formed about 150 million years ago. During the past two years, there have been many more startling results from various parts of the world. It now looks as though the land masses of the northern hemisphere have moved collectively some 40° northward from the equator, while both India and South Africa appear to have been much nearer to the South Pole several hundred million years ago.

These substantial changes in latitude may have been attended by a relative drift between the continents as required by the continental drift hypothesis, or they may represent a movement of the crust as a rigid whole across the poles—often called polar wandering. At present it seems as though relative drift has occurred, but the experimental observations are very incomplete. It should be possible, by piecing together evidence from rocks of all ages and lands, to resolve this question during the next few years.

Dr. A. E. M. Nairn gave an account of the work carried out by members of the group working for the past five years under Prof. S. K. Runcorn, first at Cambridge and later at King's College, Newcastle upon Tyne. Rocks have been collected from almost every geological formation in Great Britain, and from many formations in North America, Europe and South Africa.

Speaking of the evidence for polar wandering and continental drift, Dr. Nairn said that the results of palæomagnetic measurements on rocks of a particular locality and geological period are best expressed in terms of the pole position, which is calculated on the assumption that the direction of magnetization corresponds on the average to that of the axial dipole field at the time of deposition. The pole position obtained in this way represents the mean of many measurements, and its reliability can be expressed in terms of a 'circle of confidence', which is a statistical measure of the dispersion of the results. For a particular rock formation, the dispersion depends on the origin and geological history of the rocks, and it has been found to be least for red sandstones and basic extrusive rocks, so that on the whole the work has tended to be concentrated on these lithological types. Since red sandstones and basic extrusions are rare in the Jurassic, Cretaceous and Ordovician systems, in the northern hemisphere, these periods have not been so well studied as others. From extensive observations accumulated from palæomagnetic measurements in Britain, dating back to the Precambrian, Creer[12] assembled the pole positions in chronological order, and plotted them on a polar projection. He showed that the points can be joined into a continuous curve. Later, Runcorn[13] was able to produce a similar curve based on his and Du Bois's results from North America, which, although similar in form, showed a systematic displacement, the pole positions as calculated from the American measurements lying consistently to the west of the British. Further work has tended to confirm the existence of this discrepancy between the two curves, and there is now strong evidence for the supposition that the American continent has drifted about 2,000 miles westward relative to Europe. This drift seems to have occurred since the late Triassic period, and to have been completed before the end of the Miocene. The extension of the work to continents other than Europe and North America is generally handicapped by the imperfectly known geology; but a series of samples have been obtained from Kenya, Bechuanaland and Rhodesia. These all belong to the Karroo system, which extends in time from the Upper Carboniferous to the Lower Jurassic. The collection of reliable material from surface exposures in this part of the world is rendered difficult by the very deep weathering that has occurred, and the only satisfactory result available so far has been obtained from the Lower Jurassic basalts of the Victoria Falls area. The measurements made on these rocks suggest that the African continent has moved some 2,000 miles with respect to the poles since they were laid down.

The value of an independent check on this palæomagnetic evidence for past continental land movements is obvious, and there are, in the geological record, a number of phenomena such as the occurrence of coal facies, desert sands and red beds, salt deposits, ice ages and tree rings, which depend on climatic conditions, and which can be used for this purpose. The most reliable palæoclimatic data available at present are those obtained from fossil wind directions, which can be found by examination of dune bedding in ancient deserts; for, since the directions of the trade winds are controlled by the Earth's rotation, it is unlikely that their directions could have changed radically during the Earth's history. The subject of fossil winds is being studied at present by N. D. Opdyke at Newcastle upon Tyne and by workers in the United States, and preliminary results for a number of geological periods appear to confirm the pole positions traced for the same epochs from rock magnetic measurements. However, all palæoclimatological evidence does not support the palæomagnetic findings. One particular problem still unsolved concerns the palæomagnetic pole position during the Permo-Carboniferous period, which is situated in China, where, according to palæobotanical evidence, warm conditions prevailed at that time.

Discussing the question of reversals of the Earth's field, Dr. Nairn considered the best evidence of past reversals to be found in the work of Hospers[5], mentioned previously, and that of Irving[14] on the Torridonian sandstones of Scotland.

Dr. J. A. Clegg described palæomagnetic research carried out at the Imperial College of Science and Technology in London, and elsewhere. Discussing the subject of continental drift, he first compared the original measurements made by Clegg, Almond and Stubbs[11] on the British Triassic sandstones, which had been described earlier by Prof. Blackett, with more recent results obtained by Graham[15] fo similar Permian and Triassic sandstones in th western United States. The mean directions of magnetization of the British and American rocks correspond respectively to pole positions 155° E., 48° N., and 106° E., 34° N., both lying in eastern Asia. It appears, therefore, that there has been a considerabl change in the positions of both these land area relative to the Earth's rotational axis since Triassi times. The two positions lie approximately 20 apart, and this suggests that there may also hav been a relative movement between Britain and Nort America; but the dispersion of the results and th uncertainties in dating are such that there is grav doubt as to the significance of this discrepancy After mentioning measurements by Gough[16] on th Pilansberg dyke system of Africa, which indicat that South Africa probably occupied a position o the other side of the south pole some 250 millio years ago, Dr. Clegg went on to describe some mor recent work being carried out at present by th Imperial College group on lavas of the Deccan Tra system of India[17]. These latter rocks are found t have consistent directions of magnetization corr sponding to a position of the north geographic pole close to Florida (85° W., 28° N.), which impli that at the time when they were laid down, som 70–100 million years ago, the Indian subcontinen must have been situated considerably to the sout of the equator. This result is supported by palæoclimatic evidence, for it is well known that during the Permo-Carboniferous period there was heavy glaciation in India, and that the ice was flowing northward.

The Imperial College group has also made palæomagnetic measurements, in collaboration with Prof. J. C. Jaeger at Canberra, on certain Tasmanian Jurassic–Cretaceous dolerites, 100–120 million years old, together with overlying Tertiary basalts. The samples were taken from unoriented diamond-drill cores, so that it was not possible to measure the azimuthal direction of magnetization. However, the magnetic dips proved to be much steeper than that of the present dipole field in Tasmania, the mean directions of magnetization of the dolerites and basalts lying respectively within 5° and 7° of the vertical. This means that some 100 million years ago Tasmania was within 10° of the south pole, and that its latitude remained substantially unchanged at least until early Tertiary times. It is interesting to compare this result with that previously quoted for the Indian rocks of similar age. For, expressed in terms of pole position, it places the north pole close to a point antipodal to Tasmania in the western North Atlantic, at least 2,500 miles from the position obtained for the Deccan Trap measurements. This seems to supply good presumptive evidence of a relative movement between Tasmania and India.

Finally, Dr. Clegg described two experiments carried out on reversely magnetized rocks. The first was concerned with a volcanic tuff from Tasmania, obtained from the same borings as the basalts and the dolerites mentioned previously, but from a greater depth. A single five-foot length of core was examined, and was found to be magnetized, like the overlying dolerite, in an almost vertical direction; but whereas over the major part of its length the magnetic dip was in a normal (upwards) sense, over a single five-inch portion the polarization was reversed. The reversed and normal portions appear to be identical in all respects, and so far no satisfactory explanation of the phenomenon has been found. The result does, however, serve to emphasize the complexity of the problem of interpreting magnetic reversals. The second experiment was carried out by J. H. Leng on three Tertiary dykes from Arran. Two of these dykes, together with the baked sediments in contact with them, were uniformly magnetized in directions close to that of the present Earth's field; but in the third case, both the dyke rocks and the contact sediments had acquired a thermo-remanent magnetization in the reverse direction. Since the magnetic minerals present in the igneous intrusion are very different from those in the surrounding country rocks, it seems unlikely that this reversal of both dyke and contact sediments can be due to a Néel effect. Experiments of this type would appear to provide strong evidence for the hypothesis of the reversal of the Earth's field.

All the speakers emphasized at the meeting their belief that while information of great importance has already been obtained from palæomagnetic studies, the present conclusions must be regarded as purely tentative, and will be subject to continuous modification as the work develops.

THE CHEMICAL RESEARCH LABORATORY

THE annual open days of the Chemical Research Laboratory (Department of Scientific and Industrial Research) were held during October 2–5. Some of the exhibits by the six main research groups are described in the following paragraphs.

One laboratory has been reconstructed to house the larger apparatus used in corrosion research. A preparation room is equipped for the surface preparation of specimens, maintenance of testing equipment, and water treatment. A constant-temperature room, of brick and glass-brick construction with double glazing on the windows, is provided with humidity control. Four model boilers, each with six electrically heated tubes giving a heat-transfer rate of 7,000 B.Th.U./59 sq. ft. of tube surface per hour, are used in an investigation on behalf of the British Shipbuilding Research Association. A circulation apparatus for studying corrosion and its prevention in flowing water was in operation. The test solution is pumped from a tank into a header tank and runs back into the lower tank through the test specimens, which are in the form of mild-steel tubes. Non-corrodible stoneware pumps and glass tanks are used, so that the only metal in the circuit is the material under test.

Goods are often protected during storage and transit by enclosure in impervious wrappings. Although such wrappings prevent the entry of corrosive agents from outside, they may aggravate corrosion of the metallic contents by accumulation of relatively reactive compounds evolved from non-metallic components. At the Laboratory, corrosion in radio receivers has been traced to vapours evolved from synthetic resins and glues. Exploratory studies are being made of the corrosive effect of some likely contaminants in conditions simulating those of an undesiccated package.

The Inorganic Group provided an interesting exhibit on the use of zone-refining for the purification of some of the metals which are of interest as semi-conductors, such as bismuth, indium, tellurium and tin. Etched specimens of bismuth and tin, before and after treatment, provided a striking visible demonstration of the effect of zone-refining. Special studies have been carried out using selected impurities in the form of radioactive tracers. This method not only overcomes the analytical difficulties attendant on such work, but also, with a tracer of relatively long half-life, it enables numerous experiments to be carried out on the same ingot. The use of a cathode-ray polarograph in aiding the analytical side of the research was demonstrated, while the other analytical facilities of the Group—well-equipped spectrographic and microchemical laboratories—also attracted attention. Separation of the rare earths by ion-exchange processes and demonstrations, on the laboratory scale, of separations using the Spedding and the Loriers methods were exhibited. Large ion-exchange columns, and ancillary equipment required for processing kilogram quantities of mixed earths, were in operation. A collection of ores containing the rare earths was on view.

Exhibits in the Radiochemical Laboratory included a small pilot plant for the treatment of uranium-bearing ores. This consists of leaching, continuous filtration and clarification units by which a sulphate liquor containing the uranium dissolved from an ore can be obtained. A further unit enables the uranium to be recovered by adsorption on columns of ion-exchange resin, and finally by precipitation as a concentrate from an eluting solution. The leaching unit was being used for illustrating the possibility of leaching uranium from certain types of ores by adding sulphuric acid in such a manner as to maintain a low but constant acid concentration. A new type of resin-in-pulp apparatus was also on view. This enables uranium to be recovered from a suspension of finely ground ore in dilute acid without the necessity for filtration. It employs a series of semi-continuous belts consisting of sheets of ion-exchange membranes which move counter-currently through the flowing suspension. Part of the work being carried out on the extraction of thorium from minerals was illustrated by the demonstration of a process for obtaining thorium from monazite in which monazite is initially attacked and broken up by reaction with a strong boiling solution of sodium hydroxide. After filtration, sodium phosphate can be removed from the filtrate and thorium from the residue by differential solution with hydrochloric acid. Examples of further advances in the use of modified celluloses for the chromatographic separation of inorganic mixtures were illustrated by exhibits of promising separations of mixtures of the rare earths obtained on sheets of carboxymethyl cellulose.

A colourful exhibit by the Organic Group was the application of a new series of compounds to certain analytical problems. These coloured complexes contain as a common characteristic the pentacyanoferrate radical co-ordinated with an organic molecule. Some, owing to their intense colour, are particularly useful as spray reagents for the qualitative and quantitative detection of inorganic cations in paper chromatography. Thus trisodium pentacyano-*p*-hydroxyanilino ferrate yields blue precipitates insoluble in dilute acetic acid with many cations, and as little as 1 μgm. of the following can be detected: Cu^{2+}, Zn^{2+}, Cd^{2+}, Zr^{4+}, Mn^{2+}, Fe^{3+}, Co^{2+} and Ni^{2+}. Another reagent, prepared by the reaction of trisodium pentacyanoammino-ferrate and rubeanic acid, is especially useful in that it produces distinctive colours with different cations.

The stability of some of these complexes is so influenced by steric and constitutional factors that they can be adapted to the analysis by colorimetric methods of mixtures of certain closely-related organic compounds. Trisodium pentacyanoammino-ferrate develops a red colour with *iso*nicotinic acid, but not with its common congeners, nicotinic and dipicolinic acids, and thus provides a method for determining the purity of *iso*nicotinic acid, which is a substance with important chemotherapeutic applications. Another example shown was the estimation of the proportion of quinoline and *iso*quinoline in a mixture of these bases.

In recent years the use of water triple-point cells for setting up a thermometric fixed point has been well established. An obviously desirable extension of technique would be to use a triple-point cell containing carbon dioxide as a reference point in measurements below 0° C. Such a cell has been constructed in metal and, while strong enough to withstand storage and transport at ordinary temperatures, it enables the triple point of carbon dioxide, $-56 \cdot 60°$ C., to be reproduced to $\pm 0 \cdot 002$ deg. This cell can be obtained on loan by other workers.

Two other notable exhibits shown by the Organic Group dealt respectively with the preparation and use of finely-divided dispersions of sodium, and the convenience of oxazolidone-2 as a source of ethylene-imine for polymerization and other reactions.

The Microbiology Group illustrated various activities of sulphate-reducing bacteria: their function in the natural production of elemental sulphur in Cyrenaican lakes, the contamination of aviation fuels in storage tanks, and their use in a process for producing sulphur from indigenous raw materials. One exhibit, loaned by Rolls-Royce, Ltd., showed how the grounding of both piston-driven and jet aircraft through failure of their fuelling system, was traced to petrol or kerosene stored over water which became grossly infected with sulphate-reducing bacteria. The hydrogen sulphide produced by these organisms percolated through the fuel, forming sulphur compounds which caused heavy corrosion of fuel pumps in the aircraft, sometimes after as little as four hours flying time. To prevent future trouble, the use of water bottoms in fuel storage tanks should be avoided. Where this is not possible, a bacterial inhibitor such as chromate should be added to the water. Another exhibit illustrated pilot-plant (50 gallons) trials, carried out at the L.C.C. Northern Outfall Sewage Works, Beckton, of a process devised at the Chemical Research Laboratory for the production of hydrogen sulphide from sewage sludge enriched with calcium sulphate. Results equal to those from laboratory experiments have been obtained, and trials on a much larger scale are contemplated. The National Collection of Industrial Bacteria used illuminated panels for showing pigment production, methods of counting and cultural characteristics of micro-organisms. The Collection distributed more than 1,500 cultures last year.

Work in progress on the fractionation of polymers and on the preparation and properties of ion-exchange membranes was shown in the High Polymers Group. The mechanical and physical properties of many industrially important polymers are dependent on molecular weight; two promising new techniques for determining molecular weight distributions were exhibited. One method consists of fractionating polymers in solution by causing the heterodisperse polymer to diffuse across membranes of varied selectivity. Advantages of this procedure are that the polymer is in true solution throughout the fractionation, and relatively large amounts of material can be treated in apparatus which is much more compact than that used in techniques employing fractional precipitation or dissolution. The other method, primarily of value for low-molecular weight polymers, is a development of the technique of paper-strip chromatography to provide a rapid semi-micro procedure for determining molecular-weight distributions.

Much interest is now being shown in the possible large-scale application of multicompartment electrodialysis cells to the demineralization of brackish water, and to treatment of industrial effluents. The efficient operation of such cells is markedly dependent on the properties of the ion-exchange membranes used, and extensive studies of the preparation and properties of ion-exchange films are in progress at the Laboratory. One exhibit showed the results of a systematic study of membranes prepared by incorporating finely divided ion-exchange resins of different degrees of cross-linkage into an inert polymeric binder.

POMOLOGICAL RESEARCH IN POLAND

By L. C. LUCKWILL

Long Ashton Research Station, University of Bristol

ON May 23 the new buildings of the Polish Research Institute of Pomology at Skierniewice, about forty miles south-west of Warsaw, were officially opened by the Polish Vice-Minister of Agriculture, Mr. Szajer. This event, which marks the beginning of a new era of pomological research in Eastern Europe, was the occasion for a conference attended by Polish research workers and by twenty-four foreign delegates representing thirteen different European countries.

The Research Institute of Pomology was founded in 1951 as part of the post-war plan to co-ordinate pomological research in Poland, which previously had been conducted at many different centres controlled either by the State Agriculture Institute at Puławy or by the agricultural colleges at Warsaw, Lublin, Poznan, Kraków and Wrocław. The Institute is housed in a large three-storied building which, in addition to modern laboratory and library facilities, contains a large conference room, canteen and com-

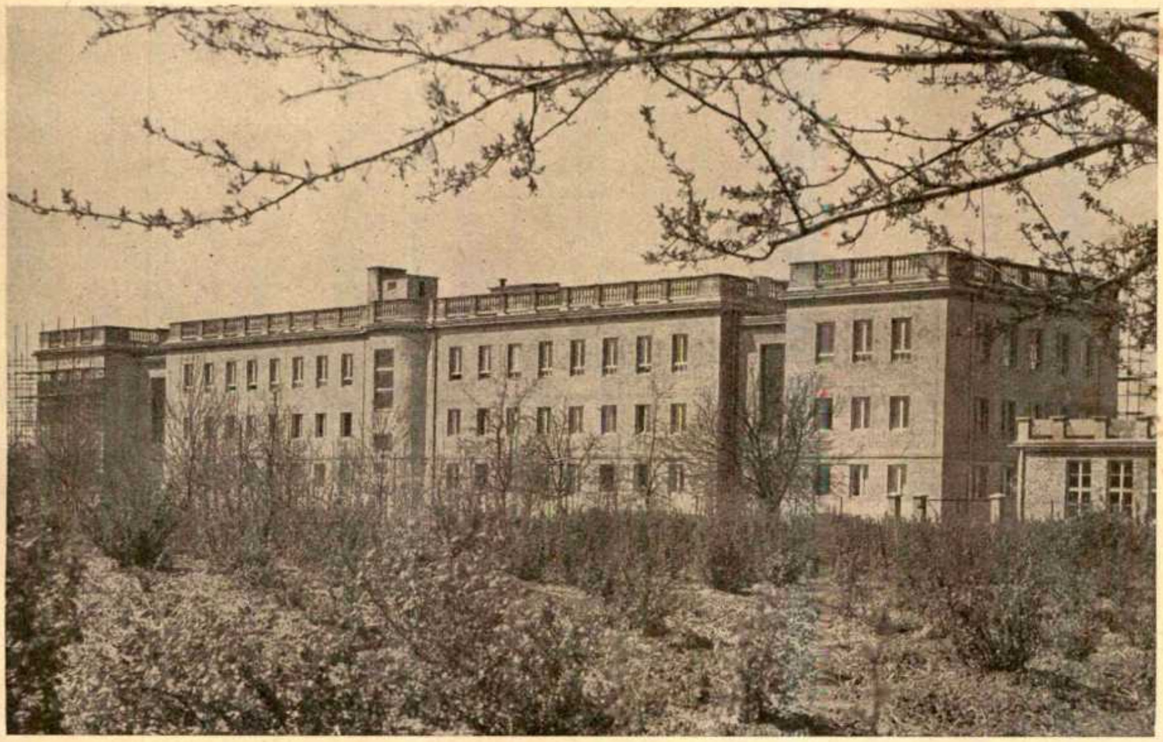

Fig. 1. Institute of Pomology, Skierniewice, Poland

mon rooms for the staff, living accommodation for visiting workers and a permanent exhibition room containing demonstrations for visiting fruit-growers. Adjacent to the Institute are a number of apartment houses for the staff, and future plans envisage the addition of an extensive block of experimental glass-houses and cold stores. On one side of the building lies the large experimental orchard of the Warsaw College of Agriculture containing demonstration experiments and an important collection of 1,800 species and varieties of cultivated fruits.

Most of the field experiments of the Institute are carried out at field stations situated in the different fruit-growing regions of the country. In all there are eleven such field stations, varying in size from 140 to 1,440 acres, each under the control of a director and small scientific staff, working in close co-operation with the staff of the Institute. The total area available for such field experiments is about 5,800 acres, of which a considerable proportion is at present devoted to extensive variety trials of tree fruits, currants, gooseberries and strawberries. The chief object of these trials is to find high-yielding varieties of good quality that are capable of surviving the extreme cold of the Polish winter. The trials themselves are well laid out and are randomized and replicated to an extent sufficient to satisfy the most fastidious statistician. In addition to these field stations the Institute has also planted many experimental and demonstration orchards on the State farms, and a few on peasants' holdings.

The creation of the Research Institute is due largely to the enterprise and initiative of the present director, Prof. S. A. Pieniążek, who returned to Poland from the United States in 1946. One of his chief difficulties throughout has been the acute shortage of trained scientific workers. At the end of the Second World War there were only four persons with Ph.D. degrees working in pomology in Poland: to-day the number has risen to about twenty, but most of the ninety-nine members of the scientific staff of the Institute are recent graduates with relatively little research experience. A few have received training in Moscow, and almost all have the ambition to work for a time in England in order to broaden their experience or to acquire specialist techniques.

The work of the Research Institute is divided into twelve departments designed to cover most of the problems of importance for fruit growing, such as soil cultivation, fruit breeding, mechanization, plant protection, and fruit technology. Winter killing is undoubtedly the most serious problem confronting fruit growers in Poland, and much research effort is devoted to the study of this problem, particularly to methods of increasing winter hardiness of trees and the selection of cold-resistant varieties. The importance of this problem is shown by the violent fluctuations of the fruit tree population during recent years. It is estimated that in 1939 there were about fifty million fruit trees in Poland. More than half of these were destroyed by cold in the winter of 1939–40, and by the end of the War the population had further decreased to twenty-two million. Extensive post-war plantings, which are still continuing, had raised the number to approximately thirty-five million in 1955; but a further severe winter during 1955–56 again wrought great havoc, particularly among pears and plums, in the orchards of central Poland.

In the Soviet Union, pomological science, under the influence of Michurin, has developed along lines different from those pursued in Western Europe and Scandinavia, and many concepts basic to Russian pomological work (for example, graft hybridization; the 'mentor' theory) are regarded with scepticism by pomologists in other countries, including, incidentally, many in Poland. Soviet pomologists, on the other hand, are equally sceptical of much Western work, particularly that relating to virus diseases in fruit crops and the application of statistical methods to field experiments. Poland, open to cultural influences from both East and West, is bound to neither school of thought, and the present policy of pomological research is to make use of those ideas and techniques that seem most appropriate to the problems in hand, irrespective of their origins. Here, indeed, in a limited field of endeavour, we have a true hybrid between Eastern and Western scientific thought which, though yet young, already manifests the marked vigour characteristic of crosses between widely dissimilar parents.

DISLOCATIONS AND THE MECHANICAL PROPERTIES OF CRYSTALS

During September 6–8, about forty metallurgists and physicists from various countries met at Lake Placid, New York, to discuss the mechanical properties of dislocated crystals. The conference was sponsored jointly by the U.S. Office of Scientific Research, Air Research and Development Command and by the General Electric Research Laboratory, Schenectady, and organized by Dr. J. C. Fisher. The discussions were quite informal and their purpose was to assess, in the light of recent work, the extent to which we understand the mechanical effects of dislocations in crystals. A few related questions were also taken up, such as the growth of whisker crystals and the nature of radiation damage.

Comparing this conference with those held in the United Kingdom in 1954, I was struck by two major changes in the subject, both of which were foreseen at the earlier conferences. First, the study of dislocations has now become very definitely an experimentalist's subject. By contrast, the development of dislocation theory has, temporarily at least, almost ceased. The reason for this is fairly clear. The geometrical and elastic theories of single dislocations and of simple arrays of dislocations have now been almost completely worked out, and only the very hard problems of the dynamics of fast-moving dislocations and of the detailed atomic structures in the cores of dislocations remain. But to understand work hardening, creep, fatigue, fracture and recrystallization, we have to study the collective behaviour of large, complex assemblies of dislocations, and the theory of this can go forward only when experiments have shown what are the decisive aspects of this behaviour in practice.

The second striking change is that the experimentalists are no longer content to look merely at slip lines. Stimulated mainly by the development of etch-pit techniques and by methods of precipitating atoms on the cores of dislocations, they now insist on seeing the individual dislocations in their specimens. As a result, when they now speak about dislocations gliding and multiplying in slip lines, and climbing out of these lines and polygonizing, they are no longer making theoretical conjectures, but are describing what they have actually seen taking place.

One of the most vivid examples of this was provided by Dr. P. B. Hirsch's motion-picture film of dislocations in aluminium foils observed by transmission electron microscopy. Here we were able to see single dislocations gliding, sometimes slowly, sometimes quickly, along close-packed planes. We saw them bow out under applied stress, interact with each other, reach unstable configurations and then run rapidly into nearby sub-boundaries. We also saw how remarkably effective an applied stress can be in breaking up dislocation nets within the crystal and driving the dislocations into boundaries, a fact often inferred previously from results of creep and recovery experiments, but never before actually seen.

It is pleasing to see how many of the predictions of dislocation theory, made a few years ago, are now being confirmed. The study of dislocation networks in ionic crystals, made visible by the precipitation of metallic atoms on the dislocation lines, has gone forward actively, and Dr. S. Amelinckx and Dr. J. W. Mitchell showed many examples of networks in silver halides, sodium chloride and calcium fluoride, which conformed closely to the patterns expected from considerations of Burgers vectors and elastic stability. Isolated closed dislocation rings and spiral dislocation ines were also seen in the calcium fluoride specimens, so confirming the ideas of Prof. F. Seitz about the condensation of point defects into platelets and on to screw dislocations. We were also shown some beautiful examples of Frank–Read sources in operation in silion, photographed by Dr. W. C. Dash, using copper atoms to mark the dislocation lines and infra-red light o photograph them.

Drs. J. J. Gilman and W. G. Johnston have developed a versatile etch-pit technique for studying dislocations in lithium fluoride. One type of etchant attacks all types of dislocations in the material, whereas another type attacks only those dislocations that have (presumably) absorbed some impurity during annealing; freshly created dislocations can thus be distinguished from old ones. The symmetry f an etch-pit differs according to whether the dislocation it marks is an edge or a screw, so that these two ypes of dislocation can be distinguished. When a islocation is pulled away from its etch-pit, that pit hen develops a flat bottom, so that the present and last positions of a dislocation can be identified. Perhaps the most outstanding of the many observaons made on lithium fluoride with this technique that, at a stress of about 1 kgm. mm.$^{-2}$, small islocation loops can nucleate, grow and multiply nto fully active slip bands in apparently perfect egions of the crystal. These intriguing results roused much discussion. It seems clear that here a omplete slip band can be formed independently of a islocation network. One suggestion, made by Dr. W. M. Lomer, is that parts of an expanding dislocaon ring may in fact jump from one slip plane to nother, by cross-slip, so that segments of dislocation nes capable of acting as Frank–Read sources may be rmed in the neighbouring slip planes. The nature f the primary defects, from which the first loops are ucleated, remains a mystery. Dr. J. C. Fisher sugsted that they may be small platelets of condensed vacancies; but so far it has not been possible to reveal them by etching.

Several experiments were described that gave evidence about the location of the original sources of slip in various crystals. Dr. W. T. Read deduced, from an observation that more dislocations are formed when a germanium crystal is bent than would be expected from the theory of plastic bending, that some dislocation sources became operative in the interior of the crystal. In a somewhat similar experiment on an aluminium crystal strained in tension, Prof. B. Chalmers deduced from the character of X-ray reflexions obtained by the Schultz method, that the dislocations must have moved into the crystal from the surface. Further evidence for slip starting at the surface was presented by Dr. T. Suzuki, who worked with potassium chloride, and the present writer, who described some work of Mr. M. A. Adams on copper. Suzuki showed that birefringent bands first appeared on two opposite faces at the beginning of slip, and that the effect of contaminating these faces with impurity caused the yield stress to increase. Adams showed that a copper crystal normally does not yield discontinuously or strain-age, but that it can be made to do so by introducing 1 per cent of zinc into its surface. These effects, which suggest that slip begins at surface sources, disappear when the zincified layer is removed.

Several examples of impurity yield points were reported; arsenic in copper (Dr. W. Boas) and oxygen in silicon (Dr. W. T. Read) both produce the effect. Dr. K. Lücke described an extensive investigation of the pinning of dislocations by impurity atoms, based on the damping of high-frequency (10^8 c./s.) oscillations. The rates of migration of impurity atoms to dislocations and their binding energies in dislocations were both measured in these experiments: for example, bismuth in lead is bound to dislocations with an energy of 0·11 eV. Dr. W. Boas showed some effects of impurities on the annealing behaviour of cold-worked copper, which Prof. N. F. Mott interpreted in terms of the anchoring of jogs by impurity atoms, so hindering the climb of dislocations. The rate of climb of dislocations was also discussed by Prof. F. R. N. Nabarro in an analysis of the straightening of kinked whisker crystals.

One point which emerged strongly at the conference is that in many materials dislocations glide rather 'stickily', suggesting that they are hindered by a large Peierls–Nabarro force. We saw examples of this in Gilman's work, in which the stress to move visible dislocations varies sensitively with temperature and rate of strain and always remains large even in apparently perfect regions of the crystal; also in silicon, in which the yield stress is very sensitive to temperature even after the impurity yield point has been overcome (W. T. Read), and in which the dislocation lines follow crystallographic directions closely (W. C. Dash) and take up positions in the slip plane which appear to be determined by their rate of glide rather than by their mutual elastic interactions. Gilman showed that fast-moving cracks (more than 10^4 cm. sec.$^{-1}$) do not produce dislocation loops at their tips, whereas slow ones (less than 10^4 cm. sec.$^{-1}$) do. Since large amounts of energy can be dissipated by slip at the tips of cracks, the stickiness or otherwise of dislocations undoubtedly plays a major part in determining the tendency towards brittleness or ductility of crystals. Even in metals, it begins to look as if the Peierls–Nabarro force is small only for slip on close-packed planes. According to Dr. A.

Seeger, the force does not make itself felt in these planes until rather low temperatures (lower than 100° K.) are reached, where the internal friction of the metal rises up to the 'Bordoni peak'. In the face-centred cubic metals, we scarcely ever see slip on planes other than close-packed ones, except possibly at high temperatures; similarly, in close-packed hexagonal metals, only the basal slip system has a flow stress that is insensitive to temperature, and the high sensitivity of other systems to temperature is strongly suggestive of a large Peierls–Nabarro force. It now seems probable that the sensitivity of the yield stress in iron is due at least partly to a large Peierls–Nabarro force, which may help to account partly for some of the observations on delayed yielding in iron that were reported to the conference by Dr. D. S. Wood.

In the discussions of solid-solution hardening and radiation hardening, the point was brought out from the work of Prof. R. W. K. Honeycombe and Dr. T. Blewitt that the yield stress of such materials is quite a sensitive, parabolic, function of temperature. Dr. H. Suzuki offered an explanation of the solid solution case in terms of the impurity yield-point mechanism, and several views were expressed about radiation hardening. Dr. J. Friedel suggested that vacancies agglomerated into large voids along dislocations, Dr. T. Blewitt considered that aggregates of point defects formed in the lattice would produce a type of precipitate hardening, while the present writer explored the possibility that the absorption of point defects by dislocations would cause the latter to climb out of their glide planes and thereby give them a large Peierls–Nabarro force.

The discussions of work-hardening were centred mainly around the nature of the obstacles responsible for work-hardening. Dr. A. Seeger showed that slip dislocations escape from their barriers in the slip planes by undergoing cross-slip and he proposed a variant of the Lomer–Cottrell barrier in which slip dislocations in screw orientation would become locked against barriers formed from two secondary slip systems. Prof. N. F. Mott raised the question of the behaviour of such systems on unloading. It seemed to the writer that the back-stress from its own piled-up group of dislocations could not be the reason why a given dislocation source ceased to act during unidirectional straining; for if this were the case, the stored elastic energy in the system would be nearly equal to the total work done, and most of the plastic strain would be recovered during unloading. The hardening of the Frank–Read sources must originate in some other way, perhaps from the internal stresses due to other nearby dislocation groups, as in the theory suggested a few years ago by Prof. Mott.

The problem of understanding fatigue failure still appears very difficult. The idea that vacancies are formed during the glide of dislocations has met with difficulties, mainly because we are still not sure how dislocations can produce vacancies; in fact, when gliding screw dislocations intersect they are more likely, if they produce any point defects at all, to produce interstitials rather than vacancies. Prof. Mott proposed a new mechanism whereby a gliding screw, oscillating to and fro with the applied stress, jumps cyclically from one plane to another by means of cross-slip at the ends of its path; this causes the material between these planes to be squeezed out of the crystal, leaving behind a void in the slipped region. This ought to be just the type of process that could be examined directly by the new experimental techniques mentioned above.

Interest has grown rapidly in recent years in the mobilities of various types of defects in solids, particularly at very low temperatures. Prof. J. S. Koehler, Dr. T. Blewitt and Dr. W. Boas summarized recent work on the annealing of point defects in quenched, irradiated and cold-worked metals, and Dr. G. Leibfried concluded that zero-point motion may contribute to the mobility of point defects at very low temperatures, but is unlikely to be important in the motion of dislocations because the vibrational modes useful for helping dislocations over barriers have long wave-lengths and low Debye temperatures. Dr. Blewitt showed that copper crystals can be work-hardened in liquid helium up to yield stresses greater than one per cent of the elastic constant, and that at these high stresses it is possible to pull partial dislocations away from one another, so forming stacking faults and deformation twins. Prof. C. S. Barrett described some recent work by Dr. P. Haasen and Dr. A. Kelly which showed that nickel and copper crystals develop yield points after plastic straining unloading and reloading, in liquid helium, and Dr Blewitt mentioned that internal friction experiments have shown that dislocations can become pinned as a result of neutron irradiation at 17° K. Certainly, one of the most fascinating developments of the subject in recent years is the discovery of so much evidence fo atomic movements in crystals at temperatures of a few degrees above absolute zero.

A. H. COTTRELL

OBITUARIES

Mr. H. N. Ridley, C.M.G., F.R.S.

MR. H. N. RIDLEY died in his one hundred and first year at his home at 7 Cumberland Road, Kew, on October 24. On the occasion of his hundredth birthday (December 10, 1955), Mr. J. W. Purseglove contributed to *Nature* an appreciation of Ridley's many-sided activities in Singapore and Malaya, and the reader is referred to this for a fuller survey of his life and work.

He was born at West Harling, in Norfolk, son of the Rev. Oliver Matthew Ridley and Louisa Pole (Stuart). He was proud to count among his ancestors Nicholas Ridley (Bishop of London, 1550–55), William Penn, and the third Earl of Bute, who wa botanical adviser to the Princess Augusta, founde of the Royal Botanic Gardens, Kew.

Ridley took all Nature for his province. In hi boyhood he was interested mainly in birds an insects; after studying natural science at Oxford h was awarded a scholarship in geology; he cam finally to an intensive study of botany almost as a accident when, having failed to obtain a zoologica post, he applied in 1880 for a post in the Botan Department of the British Museum (Natural History In the following eight years he specialized in th study of tropical Monocotyledons, but did not neglec other groups of plants; and he maintained an activ interest in animal life, especially in the relations between plants and animals, in insects as pollinators and pests, and in birds and mammals as distributors of plants.

He thus went to Singapore in 1888 (as director of Gardens and Forests, Straits Settlements) well equipped to make the pioneer investigations of plant and animal life which were then needed, and to them he devoted the next twenty-three years of his life. In addition to the wide scope of his knowledge and interest, his other prime characteristic was the intensity of purpose with which he applied himself to everything that he did. With small financial resources, and little help from others, he achieved original pioneer work of a variety and scope such as few men have accomplished in a comparable period of time.

By his investigation of the tapping of Para rubber trees, and his persistent advocacy of the need for, and possibility of, a plantation rubber industry, he was largely responsible for making possible the development of modern Malaya. He was a wonderful field botanist, because he knew and could recognize such a great range of plants; he knew at once if he was looking at something new and interesting, when another collector might pass it unnoticed. He took every opportunity of travelling, and made by far the largest single contribution to our present knowledge of the Malayan flora. Several species of plants are still known only from his original specimens.

In addition to Para rubber, Ridley cultivated experimentally many other useful plants from outside Malaya. He wrote reports upon these plants, and on the techniques of handling them for local use. He also investigated, and reported upon, the many kinds of timber trees and other useful plants of the Malayan forest. His zoological papers were numerous and varied.

But because he had so many interests, and attempted such a wide range of work, and because he had so little help, everything he did was done in a hurry, and there is frequent evidence of this in Ridley's published papers and books. One thing he apparently had not the ability (or the patience) to do was to correlate his observations with those of other people; and through the habit of hasty work he apparently lost the ability of making careful and methodical records of his own observations. But it is not as a finished worker one must judge him; he was a pioneer, and showed the way for others who came afterwards, each to deal with only a fraction of the field he tried to cover.

Among those who travelled with him on his expeditions (as some of them have told me) Ridley had the reputation of being a good companion, always cheerful and resourceful. In his later years he had an inexhaustible fund of stories of his life in Malaya, and greatly enjoyed recounting them; from them one could appreciate his zest for life. He had a fine scorn of those with whom he disagreed, but a warm heart that made him beloved by many, especially by those to whom he quietly and generously gave practical help in time of need. One of his larger benefactions, which (at his own request) was never publicly announced, was a considerable gift towards the cost of A. F. R. Wollaston's expedition to New Guinea in 912–13 (see *Geographical Journal*, 43, 248–268).

At the age of eighty-two, Ridley married Lily Doran, who, with her sister, most devotedly cared for him during his later years and in his final illness.

R. E. HOLTTUM

Prof. Doris L. Mackinnon

AFTER an illness lasting almost three months, Prof. Doris Livingston Mackinnon died on September 10, at the age of seventy-two. She was the eldest of five talented children born to Lachlan Mackinnon, advocate of Aberdeen, and Theodora Mackinnon, *née* Thompson, of London, and she was born on September 30, 1883. Doris could draw skilfully, she had a good knowledge of music, and she had a great literary gift. Why then did she choose science as a career? Her father, who was a lover of animals, as well as an ardent amateur botanist, ornithologist and astronomer, would take the children for rambles in the country, to observe Nature in all its forms. Another influence in Doris's life was that of the late Mrs. Ogilvie Gordon, a noted geologist, who encouraged her to take up science seriously. She took her B.Sc. at the University of Aberdeen with the subjects botany, zoology and geology, graduating with distinction in 1906 and being, as I believe, the second woman to be capped in that University. A Carnegie Scholarship then enabled her to spend one year in the laboratory of Richard Hertwig at Munich, some months at the Biological Station at Roscoff, collaborating with M. F. Vlès in protozoological research, and a further period in the Quick Laboratory at Cambridge under the supervision of Prof. G. H. F. Nuttall.

During 1908–9 Miss Mackinnon acted as personal assistant to Prof. J. Arthur Thomson at Marischal College, Aberdeen, and in 1909 she was invited by Prof. W. D'Arcy Thompson to become his assistant at University College, Dundee. She remained in Dundee until the spring of 1916, and was then granted leave of absence to undertake war-work. During these years she established her reputation both as a brilliant lecturer and a protozoologist. In addition to her academic work, she gave a number of popular lectures in Dundee, Perth and Aberdeen, and by 1914, when she gained the degree of D.Sc. at Aberdeen, she had published fourteen papers, most of them dealing with the parasites of insects. In May 1916 she came under the influence of Clifford Dobell, who trained her at the Wellcome Bureau in matters relating to the study of amœbic dysentery. Another potent influence was that of her father's first cousin, Sir Patrick Manson. She then took up a War Office appointment as protozoologist attached to military hospitals. At the 1st Western General Hospital and at the School of Tropical Medicine, Liverpool, and later (1917) at the University War Hospital, Southampton, she collaborated with a number of colleagues in the publication of several important papers and reports concerned with *Entamoeba histolytica* and amœbic dysentery.

In 1918, when D'Arcy Thompson accepted the chair at St. Andrews, the Council of University College, Dundee, obtained her release from war-work, and she returned in April, running the Zoology Department single-handed. A year later she was appointed Prof. Arthur Dendy's senior lecturer at King's College, London, and in 1927 she became professor of zoology in the College.

Prof. Mackinnon's contributions to the original literature on her subject, most of which were concerned with the parasitic Protozoa, numbered about forty papers. Her sound knowledge of German was utilized in the translation of J. von Uexküll's "Theoretische Biologie" (1926) and in a translation of a musical book by Paul Mies, "Beethoven Sketches, an Analysis of his Style, based on his Sketchbook" (1929). She also edited Berg's "Nomogenesis". Another side of her character is revealed by numerous articles, many of them studies of children and some of them childhood memories, which were published during the period 1913–19 in the *Manchester Guardian* and other periodicals. A course of broadcast talks for schools formed the basis of her book "The Animal's World" (1936), which appeals to adults even more than to children, and which reached an enlarged new edition in 1950. For many years Prof. Mackinnon worked on the preparation of her *opus magnum*, an illustrated text-book on protozoology, but she did not live to see this work quite completed. There is every hope, however, that it will appear in the near future, and those knowing the unusually fine quality of her teaching will look forward to its appearance.

As a colleague of Prof. Mackinnon for twenty years, I can vouch for the smoothness with which she ran her Department. She was an able administrator, and such a friend to her staff that her merest wish was equal to her command. Always ready to seek advice on such technical matters as perplexed her, she was equally ready to offer guidance to staff and students, whether on academic or personal matters. Many would testify to her kindness to them, for she lived for communion with her students, past and present. How she found time and energy to write to so many students so often and so fully, I for one cannot guess; but her self-imposed duty must have given joy both to herself and to many, particularly during the arduous years of war. All who have known Prof. Mackinnon will feel deeply saddened by the passing of a charming and gracious lady.

BEN DAWES

NEWS and VIEWS

Appeal from the University of Szeged, Hungary

THE following communication, dated November 4, has been received from Prof. A. Szent-Gyorgyi, of the Marine Biological Laboratory, Woods Hole, Mass.: "I obtained from Hungary the wire quoted below, posted on November the 3rd, 6 p.m. I should be grateful if you could give room to it on your pages. 'To A. Szent-Gyorgyi, Marine Research Laboratory, Woods Hole, Massachusetts, U.S.A. The University of Szeged makes the following declaration: the newly born democratic Hungary wants to live in peace and friendship with its neighbours and all peoples of the world. We call on all Universities to support and help us with their moral authority in our endeavour to restore peace and independence to our country, which are the basic conditions of all scientific work. We ask all those men of learning with whom we established contacts at home or abroad, to come to our help. Up to the present we strived with all the modest means at our disposal to serve the progress and better future of mankind. We want also in the future to do everything possible to work in concert with the researchers of the whole world. We would be overjoyed if this desire could be fulfilled. We ask you to make this declaration known in possibly wide circles.' Here follows a great number of signatures, representing practically the whole senate and faculty."

Nobel Prize in Chemistry for 1956

THE Nobel Prize in Chemistry has this year been divided between Sir Cyril Hinshelwood, president of the Royal Society and Dr. Lee's professor of chemistry in the University of Oxford, and Prof. N. Semenov, of the Academy of Sciences, Moscow, for their work on the kinetics of chemical reactions.

Sir Cyril Hinshelwood, F.R.S.

SIR CYRIL HINSHELWOOD was elected president of the Royal Society in 1955, and reference was made to his many interests in *Nature* of December 10, 1955, p. 1101. This further honour which has come to him is a worthy recognition of the fundamental significance of his work on the study of chemical processes by kinetic methods.

Academician N. Semenov

NIKOLAI NIKOLAIEVICH SEMENOV, member of the U.S.S.R. Academy of Sciences and director of the Institute of Chemical Physics in Moscow, to whom, jointly with Sir Cyril Hinshelwood, this year's Nobel Prize for Chemistry is awarded, has long been known to all chemists for his outstanding contributions to the theory of chain reactions and explosions. The first major impact of his ideas on the world came with the explanation in terms of branching reaction-chains of the sudden ignition on slight increases of pressure of mixtures such as phosphorus vapour and oxygen in which, below the limiting pressure, there is little sign of chemical activity. His book, "Chemical Kinetics and Chain Reactions", published in England in 1935, contains an exhaustive analysis of the applications of the chain-theory to reactions of the most varied types, but notably to those involved in combustion processes. Among the many fruitful ideas which Semenov has advanced is that of degenerate branching, in terms of which some of the rather mysterious phenomena associated with the induction periods of oxidation reactions can be understood. Less well known, because published only in Russian, is his work on the propagation of explosion waves. Semenov has been, and still is, the centre of a distinguished group of Russian workers in various fields of physical chemistry, but principally devoted to the study of the mechanism of chemical transformation. It is an interesting circumstance that the two chemists who share this year's award have been on very friendly terms for many years, and met in Moscow on the occasion of the Academy's celebration of its 220th anniversary in 1945.

Royal Society: Medal Awards for 1956

THE QUEEN has been graciously pleased to approve the following recommendations made by the Council of the Royal Society for the award of the two Royal Medals: Dr. Dorothy M. C. Hodgkin, reader in X-ray crystallography, University of Oxford, for her distinguished work in the elucidation of the structures of penicillin, vitamin B_{12} and other important compounds by the methods of X-ray crystallography; Dr. O. T. Jones, lately Woodwardian professor of geology in the University of Cambridge, for his distinguished studies of the Palæozoic rocks, particularly in Wales, his work on sediments, his palæontological researches and the application of geological knowledge to practical problems.

The following awards of medals have been made by the President and the Council of the Royal Society: *Copley Medal:* Prof. P. M. S. Blackett, professor of physics in the Imperial College of Science and Technology, London, for his outstanding studies of cosmic ray showers and heavy mesons and in the field of palæomagnetism; *Rumford Medal:* Dr. F. P. Bowden, reader in physical chemistry in the University of Cambridge, for his distinguished work on the nature of friction; *Davy Medal:* Prof. R. D. Haworth, Firth professor of chemistry and head of the Chemistry Department in the University of Sheffield, for his distinguished contributions to the chemistry of natural products, particularly those containing heterocyclic systems; *Darwin Medal:* Dr. J. S. Huxley, for his distinguished contributions to the study and theory of evolution; *Hughes Medal:* Lord Cherwell, lately professor of experimental philosophy in the University of Oxford, for his distinguished work in many fields: the melting-point formula and theory of specific heats; ionization of stars; meteors and temperature inversion in the stratosphere.

The American Geographical Society: Medal Awards

THE Council of the American Geographical Society has made the following awards: *Cullum Geographical Medal:* Prof. J. Russell Smith, emeritus professor of economic geography in Columbia University, and author of several books on North America that have become classics in their field; *Charles P. Daly Medal:* Prof. Raoul Blanchard, long associated with the University of Grenoble, whose monumental work on the Alps will be completed with the appearance of the twelfth volume; *David Livingstone Centenary Medal:* Prof. George McCutcheon McBride, emeritus professor of geography in the University of California at Los Angeles, a leading authority on problems of economic and cultural geography in Latin America.

The National Zoological Park, Washington: Dr. William M. Mann

DR. WILLIAM M. MANN, who has been director of the National Zoological Park at Washington for thirty-one years, retired on October 31. Dr. Mann, who recently reached the statutory retirement age of seventy, was the fifth director the National Zoological Park has had since it was established by the Smithsonian Institution in 1889. He began his career in 1916 as an entomologist with the Bureau of Entomology, United States Department of Agriculture. It is widely recognized that under Dr. Mann's direction the Washington zoo has become one of the best and most representative collections of living animals in the world. The physical equipment of the zoo also has steadily improved, and during Dr. Mann's administration four modern exhibition buildings were added and others are planned. Dr. Mann is one of the world's greatest authorities on ants. He has collected and studied these insects around the globe, and only last year he presented to the Smithsonian Institution his huge personal collection of these insects, numbering more than 117,000 specimens. For the zoo Dr. Mann has made trips to many foreign lands to obtain live animals for the collection. For example, in 1926 he headed the Smithsonian–Chrysler Expedition to East Africa, in 1937 a National Geographic Society Expedition to the East Indies, and in 1940 the Smithsonian–Firestone Expedition to Liberia. He will continue his association with the Smithsonian in the capacity of honorary research associate, the Institution's highest honorary scientific designation. Dr. Theodore H. Reed, of Portland, Oreg., who has held the post of chief veterinarian of the zoo since July 1955, has been appointed acting director of the National Zoological Park.

The D.S.I.R. Research Council

THE Department of Scientific and Industrial Research Act, 1956, has now come into force, and the composition of the new Council of the Department is: Sir Harry Jephcott, chairman, Glaxo Laboratories, Ltd. (*chairman*); Sir Eric Ashby, president and vice-chancellor, The Queen's University of Belfast; Prof. C. E. H. Bawn, Grant-Brunner professor of inorganic and physical chemistry, University of Liverpool; Sir Hugh Beaver, managing director, Arthur Guinness, Son and Co., Ltd.; Prof. P. M. S. Blackett, professor of physics, Imperial College of Science and Technology, University of London; Mr. H. Douglass, general secretary, Iron and Steel Trades Confederation; Sir Walter Drummond, a director of George Angus and Co., Ltd., and also Smith's Dock Co., Ltd.; Mr. W. L. Heywood, general secretary, National Union of Dyers, Bleachers and Textile Workers; Dr. Willis Jackson, director of research and education, Metropolitan-Vickers Electrical Co., Ltd.; Sir Philip Johnson, deputy chairman, R. and W. Hawthorn, Leslie and Co., Ltd.; Prof. E. A. G. Robinson, professor of economics, University of Cambridge. Dr. H. W. Melville, secretary of the present Advisory Council, will be secretary of the new Council. Payment of £1,000 a year to the chairman and £750 a year to each member of the Council is authorized under Section 2 (5) of the Act.

Large Heavy-water Reactor at Harwell

BRITAIN'S first large heavy-water reactor, DIDO, built for testing materials and making powerful radioactive isotopes, has started operating at Harwell. DIDO will develop about ten megawatts of heat at full power, and its neutron flux will be about 10^{14} neutrons per sq. cm. per sec. It is the most powerful experimental reactor in Western Europe. Heavy water is used as the moderator, and the fuel is highly enriched uranium. The reactor will be formally opened by Sir Cyril Hinshelwood, president of the Royal Society, on November 21. The name DIDO is derived from the formula D_2O for heavy water.

Precautions in handling Radioactive Isotopes

PARALLEL to the increasing use of radioactive isotopes by industry, there has been an increase in the demand for advice on the precautions required to ensure safe handling and disposal of radioactive materials, and both the Health Physics Division and the Isotope Division's Advisory Service on the Industrial Applications of Radioisotopes of the Atomic Energy Research Establishment, Harwell, have been active in this regard. During 1955 it was decided to supplement the services provided by the Divisions by a series of short courses of instruction on radiological protection, and the first course was held during November 1955 at Harwell. The course lasted four days and consisted of lectures, demonstrations and practical work. Cyclostyled summaries of the nine lectures delivered during the course have been collected together in *A.E.R.E. H.P./L.*23, an unclassified publication which is now available for purchase (H.M.S.O., 13*s*. 3*d*. net). The subjects of the lectures included: "Elements of Nuclear Physics" (R. A. Faires); "The Organization of a Radiation Protection Service" (I. S. Jones); "Units in Radiation and the Detection of Radiation" (H. J. Dunster); "The External Radiation Hazard and its Control" (E. M. Flew); and "Decontamination and Waste Disposal" (R. H. Burns).

Traffic Problems in Britain

THE present level of use of motor-vehicles in Great Britain was reached many years ago in the United States and it is desirable that we should profit by experience there when we decide how to tackle our traffic problems. That presumably is the object of the recent P.E.P. pamphlet, "Solving Traffic Problems: Lessons from America", and in it one might reasonably expect to find factual information as to the value or otherwise of American practice. Unfortunately, the report is confined almost entirely to quotations of American opinion, some of which fairly certainly comes from people with vested interests in particular branches of transport. It is thus difficult to know from the supporting evidence what value to attach to the conclusions drawn. It is particularly important that we should draw on American experience of the value of urban motorways in solving traffic problems. The report, however, gives no information such as Mr. Arthur S. Hodgkiss, the eminent and experienced expert from New York, gave to the recent conference in London on urban motorways when, in speaking of conditions in Great Britain, he expressed the view that "the development of urban motorways as a part of a national system of modern highways will more than pay for itself through direct and intangible benefits". Instead, the report emphasizes possible difficulties which might arise from the use of these roads by large amounts of car traffic travelling to and from work. Of course, the report is right in drawing the conclusion that the urban motorway will not of itself solve the traffic problem of Britain, which must be considered in relation to other factors and in particular to public transport and to parking policy.

It is disappointing, however, that the report can provide no clear indication from the United States as to whether the various restrictive measures that it seems to advocate are likely to be either acceptable or successful; whether in fact a proper balance which the report says "must be achieved between private and public transport" has been achieved anywhere; and whether it would be considered in the United States profitable to wait until traffic needs are "properly defined", whatever that may mean in present rapidly changing conditions, before getting on with the job. Great efforts should, of course, be made to collect facts—indeed, the Americans are the world's great fact collectors; but in reviewing American opinion, it is significant that Mr. Hodgkiss recommended the building of one urban motorway in Great Britain, so that we could see for ourselves the advantages that it gave, and suggested that if we studied too long in highway matters everyone became scared. This is an American 'get-on-with-the-job attitude' to which the report does not refer, but which is still held strongly in America's biggest city. It is indeed true that the United States has not solved the problem of traffic congestion; but it is a fact that the American cries out for more and more urban highway capacity. It would be wrong to convey the impression that the urge is diminishing, although it is right to say that more thought is being given to the better integration of all forms of transport, and to the conditions of use and to the provision of parking facilities.

Water Research News

RESEARCH in Great Britain on problems concerned with the availability and treatment of water for domestic supply was, for many years, carried out mainly by the technical staffs of local authorities. It had long been felt, however, that some central organization for conducting research in this field was desirable and the Institution of Water Engineers formed a Research Committee which, working through a number of groups, stimulated work on some of the many problems with which the water industry is concerned. This organization, though it did a great deal to foster research, suffered from the disadvantage that it had no permanent staff and could therefore act for the most part only as a co-ordinating body. In 1953 the British Waterworks Association, which represents all the public water undertakings in Great Britain, in conjunction with the Institution of Water Engineers, formed a Water Research Association, which last year appointed a permanent staff, housed, for the moment, in a large house at Redhill, Surrey. It is this body which has just issued the first number of *Water Research News*, a publication which is very attractively written and produced. It contains notices of two of the first technical publications of the Association—on instruments available for the detection of leaks in water mains, and on the treatment of aggressive water by aeration—together with short articles on the permeability of polythene to coal gas (a problem which has arisen in a few instances where polythene water pipes have been used), and on cathodic protection of buried mains.

Spaceflight

THE British Interplanetary Society was founded in 1933 to promote the development of interplanetary exploration and communication by the study of rocket engineering, astronomy and other associated sciences, and it now includes among its members many British and foreign workers prominent in these fields. For many years the Society has published a bi-monthly journal, issued free to members, containing original papers of a highly technical and research nature. However, there is now a growing public interest in astronautics and since one of the Society's aims is to ensure the spreading of correct information, a new publication, *Spaceflight*, in addition to the Society's journal has been launched. *Spaceflight*, the first popular magazine of its kind, will appear quarterly and aims at giving a picture of the research work being undertaken as well as discussing related historical and astronomical matters. The first number contains a typical 'mixed bag'. The introductory article "Flight into Space", by W. N. Neat, gives a general introduction to the new science of astronautics and clears up a number of popular misconceptions about the basic principles and methods to be used. "Ideas behind the Rocket", by D. Hurden, is a very clear statement of the principle of rocket propulsion, what rockets look like and of the performance to be expected, and "The Vanguard

Project", by K. W. Gatland, is a 7,000-word article in which the United States of America's satellite project —called "Vanguard"—is explained in considerable detail and with numerous illustrations. The orbit selected for the satellite is inclined at 40° to the equator, and the launching is expected to be made before the spring of 1958 from the proving ground at Cape Canaveral, Florida, in a direction between 28° and 35° south of east. The satellite will move in an ellipse about the Earth, coming perhaps as close as 200 miles on one side and swinging out to as far as 800 miles on the other. It will complete a full circuit every ninety minutes. Details are also given of other proposed satellites to be launched as part of the programme of the International Geophysical Year and of the methods of tracking the progress of the satellites.

The Cambridge Instrument Co., Ltd.: 75th Anniversary

THE Cambridge Instrument Co., Ltd., celebrated the seventy-fifth anniversary of its foundation this year, and in commemoration of this interesting event a 28-page illustrated brochure has been issued in which the history and development of the Company are briefly outlined. The Company was one of the few pioneers in the introduction of instruments into industry, and it has played an important part in the subsequent progress over the years from the time when the scientific instrument was solely a university research tool to the present day when instrumentation is capable of controlling a complete factory. Some well-known instruments—the rocking microtome, the thread recorder, the electrocardiograph, the Wilson cloud chamber, Mallock's calculating machine, to mention but a few of those referred to and illustrated in the brochure—the Cambridge Instrument Co. can rightly claim as peculiarly its own. The original personnel consisted of Horace Darwin, a mathematician and a genius at designing instruments on kinematic principles; Dew-Smith, a wealthy experimenter; three mechanics and two boys. To-day, the Company has two factories and a head office and showrooms in London (13 Grosvenor Place, S.W.1); a factory in Cambridge; a separate mechanical thermometer division at one of the London factories; an associated American company; and representatives in most countries overseas.

The Miripinnati: a New Order of Teleost Fishes

THE creation of a new order of vertebrates is worthy of notice, even if it is only yet another order of fish. The teleosts are nowadays divided by many systematists into thirty or more orders, and in Dana Report No. 42 (pp. 34+1 plate. Copenhagen: Andr. Fred. Høst and Son, 1956; 10 Dan. kr.) E. Bertelsen and N. B. Marshall propose that four newly described species of teleost fish are sufficiently distinct to constitute a new order, the Miripinnati. The four species fall into three genera and two families. They are all oceanic, pelagic or bathypelagic fish, scaleless and apparently feeding on Copepods. One species, *Mirapinna esau*, known from a single specimen caught in 1911, is remarkable in having the body covered with 'hair', composed of branched outgrowths of the epidermis which bear glandular cells of an uncertain nature. The lateral-line organs of *Mirapinna* are raised on projections. In the second family, the Taeniophoridae, the skin is smooth and the lateral-line system apparently reduced; larval stages of members of this family are described. The Miripinnati are considered to be related to the order Iniomi.

Announcements

THE Royal Society is holding a conversazione and exhibition on November 21 to celebrate the tercentenary of the birth of Edmond Halley (see *Nature*, October 27, p. 891). The exhibits have been chosen by a special Tercentenary Committee of the Society under the chairmanship of Sir Edward Bullard.

THE 123rd meeting of the American Association for the Advancement of Science will be held in New York City during December 26–31, with headquarters in the Statler Hotel. In addition to the eighteen sections of the Association, eighty-five affiliated and associated societies will be holding meetings. Further information can be obtained from Sidney S. Negus, Medical College of Virginia, Richmond, Virginia.

THE following appointments have been made in the University of Birmingham: Dr. J. S. C. McKee, lecturer in physics; W. G. Ainslie, lecturer in engineering production; J. F. Soothill, lecturer in experimental pathology (metabolic diseases).

DR. D. S. BERTRAM, reader in entomology at the London School of Hygiene and Tropical Medicine, has been appointed to the University of London chair of medical entomology tenable at that School, in succession to the late Prof. P. A. Buxton. The title of reader in statistics in the University of London has been conferred on Dr. N. L. Johnson in respect of his post at University College.

COMMENCING January 12, a course of twelve lectures and appropriate practical work, designed to survey the principal branches of chemistry in which small-scale methods have been successfully applied, will be held on Saturday mornings, from 9.15 a.m. to 12 noon, at Norwood Technical College, Knight's Hill, London, S.E.27.

THE Thames Valley Section of the Royal Institute of Chemistry has arranged a symposium on "Techniques in Polymer Science" at Courtaulds' Research Laboratory, Maidenhead, on November 30 at 2.15 p.m. The topics to be considered include light scattering and osmometry, chromatographic fractionation, infra-red methods, surface films, tracer techniques and kinetic techniques. Further particulars can be obtained from the honorary secretary of the Section, Dr. P. F. Holt, University, Reading.

THE Fourth General Assembly and International Congress of the International Union of Crystallography will be held in Montreal during July 10–17, 1957, and will be followed by two symposia on July 18 and 19, dealing with physical techniques of crystallographic interest and with electron diffraction, respectively. A brochure on the Congress can be obtained from the secretaries of the national committees of the member countries of the Union; from the general secretary of the Union, Dr. D. W. Smits, Laboratorium voor Anorganische en Fysische Chemie, Bloemsingel 10, Groningen; or from the secretary of the Canadian Committee, Dr. W. H. Barnes, Division of Physics, National Research Council, Ottawa 2, Ontario (envelope to be marked 'Personal'); or from the chairman of the Programme Committee, Dr. W. N. Lipscomb, School of Chemistry, University of Minnesota, Minneapolis.

THE Society for Analytical Chemistry has moved its offices, and its new address is 14 Belgrave Square, London, S.W.1.

PAPER-MAKING APPARATUS AT THE MANCHESTER COLLEGE OF SCIENCE AND TECHNOLOGY

THE Paper-Making Section of the Textile Chemistry Department of the Manchester College of Science and Technology has been given laboratory equipment worth £5,000 by the Reed Paper Group. Mr. T. E. G. Baker, a director of Albert E. Reed and Co., Ltd., handed over the apparatus officially on October 24. The gift was received by Dr. B. V. Bowden, principal of the College, at a small ceremony attended by representatives of the Northern District of the British Paper and Board Makers' Association, executives of the Reed Paper Group and members of the College staff.

Although classes in paper technology were held in the Mechanics Institute, which preceded the College, they received their first big impetus in 1903 when the newly founded Municipal School of Technology acquired a demonstration paper machine 24 in. wide, and set it up in the new dyehouse. This fifty-year old machine is still put to good use for teaching and research. In 1905 the Faculty of Technology in the University of Manchester was instituted, and it then became possible for students in the Department of Applied Chemistry to take paper manufacture as a principal subject when studying for the degree of B.Sc. Tech. The Paper Technology Section later became part of the Department of Textile Chemistry, in which Dr. R. H. Peters was appointed to the first chair in 1955. The University approved the institution of an honours degree course in paper technology in 1954, and the first students taking this revised course obtained their degrees in the summer of 1956. The new degree course is based mainly on physics, to meet the current requirements of the industry. The course was designed by the late Dr. W. W. Barkas, who was appointed senior lecturer in paper technology in 1949 but died at the early age of fifty-six in 1955. The previous senior lecturer, Mr. F. W. Bailey, retired in 1949 after nearly twenty-five years at the College. He was a very welcome guest at the presentation of the new apparatus.

In 1954 the Northern District of the British Paper and Board Makers' Association instituted a scholarship fund, and since 1955 seven George Rackley scholarships have been awarded to full-time students reading for degrees. These scholarships have had more effect than might be expected, as in addition to the Rackley scholars other students have joined the Department with local authority grants. Research students have always been encouraged, and a new postgraduate diploma course has just been instituted for those who wish to study paper technology for one year only. At present there are twenty full-time students in the Section and, in addition, ten part-time students taking evening and part-time day classes.

The new equipment includes a Wennberg electrically heated rotating autoclave specially designed for making paper pulp on the pilot scale. This can be used either for demonstrations with regular raw materials such as wood, cotton rags or straw, or for research on any vegetable raw material. It will treat about 2 kgm. at a time. A disintegrator and strainer on the same scale are used for breaking up the pulp and removing uncleared fibre bundles.

'Beating' is the main mystery of paper making. The cellulose fibres suspended in water are passed between bars (usually bronze), which are rubbed together under considerable pressure. It is not easy to design a beater which will do this really well in the laboratory, as stock does not circulate properly in scale models of conventional beaters at the correct solids content. The Reed Group has given the College a 'Medway' beater designed in its laboratories. Though unlike a commercial beater in appearance, it will work over a wide range of operating conditions and is particularly suitable for demonstration and research.

The 'substance' (area-density) of paper is its most important property and has always been checked during manufacture by tearing out samples at intervals and weighing them; this necessitates joins in the reels. Substance is now controlled by beta-ray gauges in which the permeability of the paper to beta-rays from a thallium source is measured in a suitable apparatus. The gift includes a Baldwin 'Atomat' apparatus which is to be fitted on the College machine. By measuring substance at both ends of the machine, the water content at the wet end can be estimated.

A low *p*H in paper is bad for its permanence, and a high *p*H is detrimental to sizing. The control of *p*H is, therefore, important, and the apparatus includes an *EIL* *p*H meter which can be coupled to Honeywell–Brown recording and control instruments. The control system can be used, alternatively, for controlling temperatures and pressures and will be useful for demonstrating the principles of controllers to students.

The Van de Korput dynamic tensile tester measures the work done in breaking paper by applied tension. It correlates better with practical behaviour than conventional tensile testers. The Somerville fractionater is used for separating paper pulps into fractions of different fibre-length, and can also be used for straining. The study of coatings for paper is increasingly important, and the gift includes a Ferranti viscometer for checking the apparent viscosity and investigating the flow of these suspensions.

F. L. HUDSON

AGRICULTURAL POLICIES IN EUROPE AND NORTH AMERICA

THE Organization for European Economic Co-operation has issued an interesting report on agricultural policies in all European countries except the U.S.S.R. and its satellites, and also in Canada and the United States*. The picture is on the whole reassuring. In Europe the population has been increasing at the rate of about 1 per cent per annum, but the agricultural output has risen by 4 per cent per annum since 1949/50. Food consumption per head has increased because of higher purchasing power; real income per head has during the past four years increased by 2·75 per cent per annum, and about half of this is spent in food.

---

* Agricultural Policies in Europe and North America—First Report of the Ministerial Committee for Agriculture and Food, May 1952. Pp. 372 (Paris: O.E.E.C.; London: H.M.S.O., 1956.) 18s.; 3 dollars; 900 fr.

The policies in the various countries have had the common aim of increasing agricultural output with the single exception of Sweden, where the present output of 107 per cent of domestic food requirements is to be reduced to 90 per cent. Planning has been generally abandoned; there are no longer targets for individual commodities as during the Second World War. What mostly happens now is that farmers are exhorted to produce all they can. A few countries have over-all targets: Great Britain is aiming at 60 per cent increased output over pre-war and has already achieved 56 per cent.

Germany has made the most remarkable recovery. During 1948–49 the agricultural output was nearly 30 per cent below pre-war; during 1954–55 it was 23 per cent above pre-war and was providing 70–75 per cent of the total food requirements in spite of the fact that the agricultural area per head had fallen by nearly one-third in consequence of the flow of refugees from Eastern Germany. There are no specific regulations—only a general requirement that food output must be as large as possible. Of the European exporters of food, Denmark, two-thirds of the export earnings of which are derived from food, aims at improved quality and higher degree of processing so as to increase the value per ton, rather than increasing the number of tons produced. The Netherlands have only the general aim of making agriculture contribute as much as possible to the national wealth: the exports include about 25 per cent of the crop output, 40 per cent of animal production and more than 50 per cent of horticultural production. In 1954, the total value of these exports was nearly 900 thousand dollars; but against this was an import of feeding stuffs, other agricultural commodities and human food amounting to 650 thousand dollars. Switzerland and the Irish Republic are among the few countries with a declared demographic aim: both desire to organize their agriculture in such a way as to maintain a large peasant population.

SIXTH INTERNATIONAL CONGRESS OF SOIL SCIENCE

The Sixth International Congress of Soil Science, organized by the International Society of Soil Science, was held in Paris at the Maison de la Chimie during August 29–September 8, under the presidency of A. Oudin, Inspecteur Général des Eaux et Forêts, France. The Congress was divided into six commissions, the chairmen of which were as follows: Dr. M. B. Russel (United States), physics; Dr. A. C. Schuffelen (Holland), chemistry; Dr. P. Simonart (Belgium), biology; Dr. E. W. Russell (East Africa), fertility; Dr. A. Muir (Great Britain), classification; and Dr. J. V. Botelho Da Costa (Portugal), soil technology. The Congress attracted the largest number of members, the enrolment being 850 representing fifty countries, as compared with the two previous congresses in Amsterdam and Léopoldville (Congo), where the attendances were 600 and 250, respectively. Naturally, the largest group was from France, the next biggest groups being Great Britain, Belgium and the Congo, Holland, West Germany, United States, Spain, Italy, the U.S.S.R., Yugoslavia, East Germany and Switzerland.

The six hundred papers presented at the Congress, most of which were available in printed form, making four separate volumes, covered a wide field of problems, the most important being the influence of climate on soils, soil structure, soil colloids, acid soils, saline and alkali soils and their reclamation, phosphate and potash contents and nutrition, nitrogen transformations, soil micro-organisms, symbiotic, non-symbiotic, photochemical nitrogen fixation, trace (oligo) elements, forest soils and desert soils. Each author was given a quarter of an hour for outlining his contribution, followed by a discussion lasting 15–20 minutes.

In the afternoon of September 1 there was an interesting colloquium on fertilization and production of paddy, in which several soil scientists from Japan, China, India, the Congo and other tropical parts of the world took active part. A session on the morning of September 8 was devoted to a colloquium on the physico-chemical aspects of mineral nutrition by the plant roots. Some interesting papers were read; but there was no general unanimity of views regarding the mechanism of this process in crop production. As a side-issue of the Congress, there was an important colloquium on leaf analysis and plant nutrient supply, organized by Dr. P. Preaud, in which an introductory paper by Prof. T. Wallace was read.

Dr. Bruin, of Holland, put forward the proposal that soil scientists hailing from temperate countries should co-operate in obtaining accurate data on the influence of nitrogenous fertilizers in crop production, and he arranged the convening of a meeting for this purpose in Groningen in November. It is well known that nitrogenous fertilizers are not much used in Asiatic countries, where the majority of the human beings of the world subsist. Moreover, only 3 per cent of the world crop yield has been attributed to artificial nitrogenous fertilizers, as reported at the meeting of the British Association in 1949 in Newcastle (see *Nature*, 164, 597; 1949): "At present only some three per cent of the world food production can be attributed to the use of nitrogenous fertilizers To raise the available food by ten per cent, that is to say, one hundred million tons, involves a fourfold increase in supplies of fixed nitrogen, at an approximate capital cost of £1,500,000,000. . . . This . . . would take a minimum of 15 years to achieve". Hence, even to-day world food production has to be mainly attributed to the soil nitrogen present in the soil organic matter or humus, the study of which from different angles attracted the attention of a large number of members of the Congress.

On September 7 there was a whole-day excursion for the study of soil profiles and other topics of agricultural importance in the Paris area. After the Congress, excursions lasting a week were made in different parts of France for the study of soils. In addition, on September 2 several members were taken around the National Agricultural Research Institute at Versailles, and the following week a group visited the Institute at Bondy, 20 km. from Paris, for training French soil scientists for work in the Colonies and research work on problems of Colonial agriculture.

The general conclusion among members was that this Congress not only contributed to the difficult problem of the amelioration of the world food situation, but also achieved progress in international fellowship and goodwill in the friendly atmosphere of the meeting and parties. The next Congress will be held in the United States in the summer of 1960 under the presidency of Prof. R. Bradfield, of Cornell University.

UNITED NATIONS TECHNICAL ASSISTANCE PROGRAMMES

THE eighth report of the Technical Assistance Board to the Technical Assistance Committee of the United Nations Economic and Social Council* describes the progress and developments during 1955 of the Expanded Programme of Technical Assistance for Economic Development and includes also some details of activities to be undertaken in 1956 and of plans for 1957. The general level of activities was markedly higher, and the contributions of 27·9 million dollars from seventy-one countries, compared with 25 million dollars in 1954, permitted assistance to be given to a hundred and one countries and territories. At the end of the year, some fourteen hundred experts were collaborating with their counterparts in the less-developed countries, and while it is not practicable to isolate the impact of technical assistance on economic development or to measure it precisely, it is clear that significant results have been achieved in many technical assistance activities.

During the year, geological maps of forty-five regions of Bolivia, to be used in prospecting for oil and other minerals, were completed, as was a similar survey in the Yemen. The first geological map of Nepal is being prepared, and a geological survey institute was set up in Afghanistan. Assistance was given in aerial surveys of forests in Brazil and Iraq, and surveys of ground-water resources in Jordan and Pakistan were being expanded, while in Indonesia a team of eight experts assisted the National Planning Board with the preparation of a five-year development plan and investment programme. Expert advice and the assistance of workers trained abroad under fellowships has enabled the production of DDT and penicillin to be commenced in Chile, Egypt, India, Pakistan and Yugoslavia, while the petrochemical industry in Venezuela has been assisted in the establishment of what will be the largest factory in South America manufacturing fertilizers and insecticides. Assistance given since 1951 to the cottage and small industries of Burma has led to these industries playing an increasingly important part in the country's economy, while throughout the world, nearly a thousand engineers, foremen and skilled workers from all branches of industry have been trained under the worker-trainee programme and large vocational training schools have been opened in Brazil, Guatemala, Haiti, Indonesia and Iran.

Port and shipping experts were assisting the Governments of Jordan and Yemen with the reconstruction of the ports of Aqaba and Ras-el-Khatib, and nineteen countries received expert advice on the improvement of their civil aviation; more than 1,140 students completed courses at schools in various countries of the International Civil Aviation Organization during 1952–55. Irrigation and land reclamation received much attention in Syria and in large river basins such as those of the Ganges–Brahmaputra, the Tigris and the Euphrates. In a pilot area of 230,000 acres on the right bank of the Ganges in East Pakistan, about one-fifth of the main canal has been excavated with the support of the Colombo Plan and the International Co-operation Administration of the United States, and it is expected that irrigation water will be available in the Kushtia area by the end of this year. Recommendations made by specialists of the Iraqi Development Board on the advice of a geologist of the United Nations Food and Agriculture Organization have led the Government to allocate 4·5 million dollars for drilling wells, fifty of which have been completed or are under construction. A pilot area on the Volta River in the Gold Coast has been brought under experimental cultivation, and in Afghanistan, Egypt, Iraq and Libya demonstrators have been trained to introduce new techniques and improved small tools to farmers. Some of the field workshops in the large-scale farm-mechanization plan of Uttar Pradesh in India have increased their output by nearly 300 per cent, and more than five hundred instructors and operators have been trained by international experts.

New varieties of cotton are being tried in Iran, and cultivation trials in Yugoslavia have given a substantially increased yield of cotton per acre. Programmes for increasing the production of wheat and rice have been undertaken in Egypt, and a scheme for developing coffee cultivation has been started in Ethiopia. Assistance given in Central America and Mexico has enabled local authorities to keep the locust plague under control everywhere except Northern Honduras, and the control of olive and fruit flies has been developed in Libya. With the building up of supplies of vaccine to control rinderpest and other animal diseases in Afghanistan, Austria, Burma, Ceylon, Ethiopia, Honduras, India, Iraq, Pakistan, Thailand and Yugoslavia, the emphasis of technical assistance has shifted to the organization of field control schemes.

The training of school teachers has from the start been an important feature of the Expanded Programme of Technical Assistance, and in 1955 more than a thousand rural teachers attended courses in Haiti, while about 2,500 have been trained in the Philippines since work started in 1953. In Indonesia more attention has been paid to training teachers for rural communities, while assistance in teaching science has ranged from the organization of a chemica laboratory and of a scientific instruments centre for the National Council of Research in Egypt to the development of institutions for arid zone research in Brazil and Peru. In Turkey the Institute of Hydrology has now reached the stage when its work can proceed satisfactorily under the direction of nationa staff, and an international team, which in 1954 completed the organization of a scientific and technica documentation centre in Mexico for the Latin American countries, is organizing a similar centre in Egypt to serve the Arab States.

Much assistance has been given to governments i training health staff, the control of communicabl diseases and in strengthening national health services. During the year about 570,000 persons in Morocco and Tunisia were treated for trachoma, a high percentage of cures being obtained. Measures were taken to protect about two-fifths of the estimated population of South-East Asia against malaria, and epidemic malaria is no longer prevalent in about half the island territories of the Caribbean; but it has become a matter of urgency to intensify the effects to eradicate malaria in these regions before the anopheline vectors develop too great a resistance to the insecticides at present used for their control. In Indonesia the mass campaign against yaws has brought the disease under control in about thirty areas, while in Thailand 7·5 million people have been surveyed and about 750,000 treated for the same disease. As examples of assistance given to improve housing conditions, the report cites the establishment in India of a research centre to study the socio-economic and technological aspects of housing development in a dry tropical climate and of another in Indonesia to study these factors in a humid tropical climate. More than a thousand Civil servants of various grades received training during the year, and in Jordan, on the recommendation of an expert on Civil Service reform, a Civil Service Department and a Civil Service Commission were set up; technical consultants in Bolivia helped to draft legislation establishing a permanent Civil Service, and the postal services in Iran, Lebanon and Uruguay have been considerably improved as a result of international advice and assistance.

---

* United Nations: Technical Assistance Committee. Eighth Report of the Technical Assistance Board. (Economic and Social Council. Official Records: Twenty-second Session, Supplement No. 5.) Pp. vi+104. (New York: United Nations; London: H.M.S.O., 1956.) 1 dollar; 7s.; 4 Swiss francs.

Although most of the experts supplied in 1955 were recruited from Europe and North America, they were drawn from sixty-nine countries and territories, and workers in receipt of fellowships studied in ninety-four. During the year, 2,431 fellowships were granted, as compared with 1,524 in 1954 and 1,195 in 1953, and there has been a growing trend towards the establishment of training institutes within countries which are receiving technical assistance. Special attention has been paid to co-ordination of the technical assistance provided under the expanded programmes and under bilateral aid programmes, while the general financial stability of the Expanded Programme considerably improved during the latter part of the year.

INDIA'S CONTRIBUTION TO THE HISTORY OF MEDICINE

THE publication, in June, of the first number of the *Indian Journal of the History of Medicine** is in itself an event of historic importance. Much of the credit for this noteworthy step is due to Prof. D. V. Subba Reddy, who founded the Indian Association of the History of Medicine nine years ago, and became its first secretary. Prof. Reddy is editor of the new *Journal*, which is to be the organ of the Association and will be published twice a year, and he will also shortly vacate his chair of physiology in the University of Madras in order to assume the duties of a chair of history of medicine, the first of its kind in India.

By the creation of a new chair and a *Journal*, India has recognized, most opportunely, the importance of a historical perspective in medicine. The Medical Education Conference, set up by the Government of India, which met in Delhi in November 1955, acted wisely in recommending that history of medicine should be included in the medical curriculum. This decision was made for several reasons. Not only has the subject a special cultural and humanistic value, but also, as the report of the Conference states, "after studying the history of medicine, the future medical practitioner will be better equipped for his profession under conditions prevailing in this country. Our people think and talk about their illnesses in terms of ideas and expressions based largely on our ancient systems of medicine. How can a physician understand fully what his patient describes as his symptoms unless he has an acquaintance with these ideas and ways of giving expression to them?"

This very appropriate argument in favour of the study of medical history may not apply in every country, but it is certainly valid for India. Events have moved rapidly, and already the report has borne fruit. Dr. Reddy is to be warmly congratulated on the high standard which has been attained in the first number of his *Journal*. It is a veritable mine of information on the early medicine of India and the East. The opening paper, which was originally an address to the Association, is a scholarly contribution by Prof. J. Filliozat (French College at Pondichery) on Ayurveda and foreign contacts, showing the links between Indian medicine and Greek medicine; Prof. P. Kitumbiah (Christian Medical College, Vellore) contributes a paper on the concept of heart and blood-vessels in ancient Hindu medicine; and Prof. M. V. Sastry (Madras) writes on training for medical practice in ancient India. Prof. Reddy himself supplies an article on Buddha's discourses on medicaments, treatment and nursing; other authors deal with nursing under ancient Indian systems, with Arabian medicine and with Rhazes' *magnum opus*, "Al-Hawi, or Continens". The *Journal*, which is well produced and clearly printed, will be published twice a year. It deserves every encouragement.

This recognition by India of the importance of history in medicine is a welcome sign of progress. Many other countries have become aware of their medical heritage. Throughout Europe, nearly every university has its chair of history of medicine and there are many institutes which serve as centres of knowledge. In the United States and in South America, especially in Brazil and Venezuela, close attention is given to the history of medicine.

Towards this widespread awareness of the value of history as a cultural and ethical basis of medical education, Britain alone shows an attitude of almost complete indifference. In London, the Wellcome Historical Medical Library and Museum continue to stimulate and keep alive an interest in the past, as also do the various societies of history of medicine, in England, Scotland and Ireland. The tale of neglect is truly surprising. Nevertheless, a more cheerful attitude is foreshadowed by the recent news that a British journal—the only one of its kind—entitled *Medical History*, will commence publication next January under the editorship of the well-known medical historian, Mr. W. J. Bishop, and will appear quarterly.

One of the strongest arguments in favour of medical history is that it directs attention to the ever-present need for an application of the principles originally embodied in the Oath of Hippocrates. Recognizing this need, the universities and medical schools of Europe, since the days of the School of Salerno, have demanded of their graduands some form of promise based upon the Hippocratic Oath, and this practice is now followed in many parts of the world. In Britain, although each of the four Scottish universities follows the age-long tradition, only two or three of the many English universities accord any official recognition to the great charter of medical conduct which has come down to us through the centuries from the time of Hippocrates. Surely a knowledge of such ethical principles, if not also of the pioneers who codified and practised them, should be regarded as a feature essential to every medical curriculum ?

---

* *Indian Journal of the History of Medicine*, 1, No. 1 (June 1956). Pp. iv+69. (Madras: Indian Association of the History of Medicine, 1956.) Rs. 8 per year (two issues) or foreign currency equivalent to Rs. 12.

Accordingly, while we in Britain may well congratulate our Indian colleagues upon their foresight in appreciating the value of the historical aspect of medicine, we may at the same time feel ashamed of our own failure to do so. There is still much to be accomplished in the reform of medical education, and, if medicine is to remain one of the learned professions, more stress must surely be laid upon ethics and humanism, which only reveal their importance during a study of the history of medicine. For Hippocrates, medicine was ever "The Art". Only as an art can it preserve its fine tradition. All honour, therefore, to India for reminding us that only by looking backward can we recapture the true spirit of medicine. In this way alone can we effectively face the future.

Douglas Guthrie

THE MYXOPHYCEAE AND CHLOROPHYCEAE OF NEW ZEALAND

Some comparatively recent American marine Floras have set a satisfactory standard against which a reader is prone to measure new works of a similar kind. Of prime scientific importance would seem to be the provision of concise but complete diagnoses of the various taxa, namely, orders, families, genera and species, including details of both vegetative and reproductive characters. Good keys based on easily discernible characters (and, so far as possible, macroscopic features of the vegetative parts of the thallus) should lead to the relevant descriptions. Good illustrations should reinforce the statements about the salient characters of the genus, both vegetative and reproductive. In some genera this would need to be supplemented by illustration of one particular character for all the species, where it is of prime taxonomic importance. Lastly, in a group of plants in which terminology is notoriously imprecise, a glossary is necessary. From the practical point of view, a Flora should be of manageable size and provided with firm covers.

The first part of the "Marine Algae of New Zealand", by Prof. V. J. Chapman, that dealing with the Myxophyceae and Chlorophyceae (*J. Linn. Soc. Lond.*, 55, No. 360, 333–501; July 1956; 42*s.*), falls short of these standards. Since the work is published in a journal, the author may not have had an orthodox Flora as his aim; but if not, what was it, as the paper has the form of such but without much of the substance ? The species descriptions are brief and would probably prove difficult, therefore, for beginners. One of the shortest is that for *Ostreobium reineckei* Born., namely: "Filaments intricately spreading, the ends of the branches consistently free". Even the newly described species are not given very lengthy treatment. Throughout the work, mention of the reproductive organs is very meagre, and illustrations of these parts of the thalli are conspicuous by their absence. References to other works are given under the binomial system; but it is not clear what rule has governed the choice of citations when it is not the original description. Keys at the beginning of each of the two sections lead to families and not orders and yet keys are given again under each order to the families of that order, so that there is considerable duplication. The Wittrockiellaceae is an exception, as it occurs under the order heading only. No glossary is provided, and sometimes the choice of terms is not good; for example, "plant body". Again, in Table 1 "exposure" is used to mean something different from the same word on the opposite page (p. 339), where it is the equivalent of emergence (cf. p. 335). "Filamentous" is also used in more than one sense, in some instances to signify the construction of the thallus and in others to describe its filiform shape.

An editor's note explains that the twenty-seven plates are reproduced as faithfully as the quality of the illustrations provided allowed, and this would appear to be the case. Legends for these plates would have added to their value, especially since notes on the illustrations are not always legible. Some of the one hundred and fifty-three text-figures, which are the work of the author and his associates, lack information about magnification and also precision as regards other details. Hence they are not always as informative as could be wished. In spite of its certain lack of perfection, the work is a considerable advance on Laing's list of 1926. In the latter, there are only seven species of Myxophyceae and forty-six Chlorophyceae, whereas in the work under review there are fifty-four species of Myxophyceae and two hundred and five species of Chlorophyceae. This indicates the amount of work which has gone into the preparation of this Flora in the comparatively short amount of time since Prof. Chapman went to New Zealand. Moreover, the paper was read at the Linnean Society more than two years ago.

Although the number of species of Myxophyceae listed is greatly in excess of that of Laing's list, the author points out that it is likely that more exist on the shores of New Zealand, and this is doubtless the case. The species known already are ones with a wide distribution in the world and there is only one doubtfully endemic species, *Tolypothrix irregularis.* In contrast, out of two hundred and five species of Chlorophyceae listed, ninety-two (47 per cent) are endemic. Some of these have a restricted distribution so far as is known at present. The new genus, *Gemina*, is characteristic of southern cold waters, and *Bryopsis* is a conspicuous genus in South Island, from which district have come species not previously described. The author goes so far as to suggest that the South Pacific is either the home of the genus or that active evolution is taking place around the shores of New Zealand. The genera *Lobata* (Ulvaceae) and *Rama* (Cladophoraceae) as well as *Gemina* (Ulvaceae), all described earlier by Chapman, are included in the Flora, as well as many new species.

In the Myxophyceae, the author has accepted Drouet and Daily's (1948) views on the classification of the Chamaesiphonaceae, but apparently not on the Chroococcaceae. The classification is said to be that of Fritsch (1945). Likewise, although the author states that the classification of the larger taxa of the Chlorophyceae in this work follows that of Fritsch (1935), this is not strictly so, but is modified, as Chapman has himself advocated in other papers. Five families, the Ulotrichaceae, Monostromaceae, Ulvaceae, Caposiphonaceae and Prasiolaceae, are included in the Ulotrichales. The Siphonocladales also has not the same limits as the Cladophorales in Fritsch's book of 1935. However, this is not the place to digress into questions of the much-debated classification of the Chlorophyceae; but it is perhaps opportune to emphasize that the existing classificatory systems rest primarily on the comparative morphology of the adult thalli and that there is need that this should be supplemented by intensive studies of developmental morphology and life-histories. As for the smaller taxa, the Chlorophyceae includes some genera which are notoriously difficult, such as *Ulva*, *Enteromorpha* and *Cladophora*, genera which would provide suitable material for investigation by one of the modern methods of taxonomic treatment such as have been used successfully for 'difficult' genera of higher plants. Here they are classed as species, varieties and forms; but in the case of *Enteromorpha*, Chapman uses "*ecad*" as a taxonomic term. This may indicate his views on the cause of variability in this genus; but its use here is valueless as well as illegitimate.

KATHLEEN M. DREW

AGRICULTURAL RESEARCH AT THE SUDAN CENTRAL RAINLANDS STATION, 1952–56

By DR. A. H. BUNTING*

Recently Senior Research Officer, Sudan Ministry of Agriculture

THE clay plains of the eastern Sudan occupy many thousands of square miles under normal annual rainfalls of 500–800 mm. In 1952, following several years of experience of partly mechanized sorghum production in part of the region[1], the Research Division of the Sudan Ministry of Agriculture opened the Central Rainlands Research Station (Tozi Research Farm) to explore its wider potentialities. Tozi is about a hundred miles south of Sennar and eight miles west of the Blue Nile (lat. 12° 30′ N., long. 34° 00′ E. approximately). The fifth season of farming and research is now in progress on about 1,300 acres, while housing and essential services have been produced for a community of several hundred, and simple offices and laboratories have been built and partly equipped. The senior staff has fluctuated from three to eight. This article records the more significant results and indications of the work so far.

The programme has been based on the study of crops in the field. About 1,700 rows and plots of a wide range of crops and varieties were grown in 1952 for observation and selection. American cotton, sorghum, groundnuts, sesame and safflower (and more recently maize) appear best suited to the conditions. In 1953 simple and separate trials were used for locating the critical ranges of crop population, planting date and fertilizer nitrogen-level in the main crops, and bulk production, mechanized so far as possible, occupied about 1,000 acres. In the third season somewhat complex multifactorial experiments were introduced to unravel the interrelations of crop population, nitrogen-level, varietal type and sowing date. Around this central agronomic core, soil, plant protection, breeding and other specialist studies have developed. Results, indications and even speculations from research and production are co-ordinated to guide the field-cropping programme each season, so that progress is by successive approximation. Conversely, an annual analysis of field-scale results opens up new lines for research.

The Environment

Over four seasons the rainfall has averaged 680 mm., against a probable normal value of around 700 mm. (about 27½ in.), mostly received during June–October. Part of it falls in cyclonic storms, the intensity of which has varied seasonally. During July–September the temperatures are buffered around 30° C. maximum, 20° C. minimum, with dew points around 20° C. In late October the southerly transit of the intertropical front suddenly brings in dry air and markedly increases evaporation-rates. The dry season (November–May) is long and hot (up to 44° C. max.), though the winter nights (December and January) are cool.

The vegetation is an *Acacia* spp. (largely *A. seyal*), open woodland with tall grass, 10–15 ft. high, with areas of open grassland of various types. The grasses are almost all upright annuals, burnt off each year by fierce bush fires. The stringent ecological conditions restrict the number of plant species to about three hundred; most of the important forms are legumes. Methods for ecological land-use selection have been broadly determined.

Soils and Water Relations

The soils are formed from deep unleached, alkaline alluvial clays, and have about 70 per cent montmorillonitic clay content and *p*H 8·5–9·0. They are fully plastic at field-capacity and crack heavily on drying, while the top few inches fall to a friable mulch. Their colour and extent of base accumulation (but not their content of clay, nitrogen or organic matter, which is less than 1 per cent under natural vegetation) are related to slight topographic differences: lower sites are darker and more alkaline, with more salts and calcium carbonate.

There is no permanent water-table in the soils. After the rains they are dried to wilting point (20–25 per cent moisture on dry weight or less) by transpiration or evaporation. In the new season, water enters, at first down the cracks and then by bulk penetration with a defined front. The ultimate depth of penetration depends on the current balance between percolation and evapo-transpiration, which in turn depends on the seasonal rainfall pattern. The penetration in undisturbed bush, where transpiration starts soon after the first showers, seems generally less than in cropped fields sown a few weeks later. Concentrated rainfall can lead to serious local flooding on unplanted land, so that permanent surface drainage systems may prove essential.

---

* Present address: The University, Reading, Berks.

Since crop roots do not enter the physiologically dry soil below the water front, the depth of soil exploited for nutrients and water also depends in part on the rainfall pattern, as well as on the root behaviour of particular crops or varieties. This broadens considerably the concept of soil fertility. Though nitrogen is the only nutrient to which responses are regularly obtained, they have been economic so far only in groundnuts and maize. Cotton and safflower, the growth of which at Tozi is primarily restricted by water shortage, do not respond, and sorghum and sesame are intermediate. The response in groundnuts perhaps reflects the relatively late stage of the crop's short life (90–95 days at Tozi) at which nitrogen becomes available from the numerous, large and apparently effective nodules. Important phosphate effects have been seen only in maize, while potash improves leaf appearance in Virginia tobacco. Zinc is important (together with nitrogen and phosphorus, though the interactions have yet to be worked out) only for maize; but this appears to be more a question of poor root penetration than of a soil deficiency in the conventional sense. No doubt if humus were more abundant, trace element shortages would be more frequent.

Crop sequence experiments were started in 1952 using a two-year design measuring residual effects of crops, fallows and fertilizer nitrogen. Many of the effects can be interpreted conventionally in terms of nitrogen or water relationships. Maize and sesame do not penetrate the soil far enough to use all the available water, so that some accumulates. Bare fallowing checks subsequent crops, even if the stored water is removed with late-sown safflower; but striking benefits of half-fallowing have been seen.

Crop Breeding and Agronomy

A collection of nearly a thousand local and introduced varieties of sorghum is maintained at Tozi. Three high-yielding combine varieties, selected from indigenous material, are being grown on a field-scale in 1956. The optimal population ranges and planting dates are found to be respectively higher and earlier than has been usual in the past, with the result that yields of 2,500–3,500 lb./acre are common in experiments, while 79 acres of bulk production in rotation averaged 2,200 lb./acre in 1955.

The highest-yielding cotton varieties tested have been the Sudan-bred blackarm resistant BAR. 7/8.1 and BAR. 7/8.2. Early sowing (June) and high population (more than 30,000 plants/acre) have given experimental yields of 1,500 lb. seed cotton/acre and more; field-production in 1955 averaged about 1,170 lb./acre on 86 acres, and a small area, about a third of an acre, following an accidental half-fallow, yielded at the rate of 2,200 lb./acre.

More than 250 uniform, classified varieties[2] of groundnuts are maintained. The upright bunch variety, Barberton, established for several years in the Sudan, has hitherto proved the best; but progeny testing has now given similar experimental yields from the newly introduced Natal Common. Yields of 1,500 lb. kernels/acre are quite common, and well over a ton has been harvested, in experiments, while field yields averaged 900 lb./acre on 106 acres in 1955. High populations (60–80,000 plants/acre) and timely harvesting are essential.

Breeding programmes in sesame aim at transferring the Venezuelan indehiscence, and the early and profuse flowering of certain American types, to the local material, which is at present used in field-production. Root penetration is relatively poor, and the crop is sensitive to drought in its later stages. While experimental yields have reached 1,200 lb./acre of seed, the general run is similar to the field-yields at 500–700 lb./acre.

Safflower, a crop extremely resistant to drought, is sown late after a summer fallow, to mature on stored moisture. Yields are unaffected by fertilizer or variations in population. Selection is aimed at the production of early and profusely flowering upright types. Field yields are 400–500 lb./acre only, although in experiments up to 1,200 lb./acre has been realized.

The work on maize nutrition at Tozi (see above) permitted the production of this crop on the clay plains for the first time in 1955. Introduced varieties including hybrids yielded 3,000–3,800 lb./acre in preliminary observation plots and rows; local Sudan material (from recent riverain silts) gave 2,000 lb./acre on 6 acres.

Minor crops studied include deccan hemp (kenaf), sunflower (where some progress seems to have been made in concentrating a self-fertilizing character), soya bean and Virginia tobacco. The local perennials Rhodes grass (*Chloris gayana*) and *Clitoria ternatea* (a prostrate legume) seem likely to be useful, perhaps in mixture, in sown pastures.

Crop Protection and Farming Practice

Though many potential sources of trouble, including stainers, bollworms, grasshoppers, stemborers and the *Puccinia polysora* rust of maize, have been recorded, no serious attacks of pests or disease have so far occurred at Tozi. Rosette disease of groundnuts is absent from the region, and the cotton varieties in use are sufficiently resistant to blackarm. Soil-borne diseases and pests of the seed-bed make it essential to use combined insecticidal and fungicidal seed dressings for sorghum and groundnuts, and for the latter a soil dressing of 1 lb./acre of dieldrin is standard practice and helps to control thrips and termites.

All land preparation, sowing, inter-row cultivation, ridging and field spraying are mechanized, though on a heavy clay soil under tropical rainfall a high degree of farming skill is necessary to use machinery efficiently. Sorghum and safflower are combined. Groundnuts can be harvested, threshed and decorticated mechanically, but so far the operations are slow and require very careful timing and organization. Cotton and sesame are harvested by hand at present. Tractor-hour records suggest that all the main crops, and particularly cotton and sorghum, are economic at the present levels of field-yield.

MARINE FISH FAUNA OF THE GOLD COAST

By Dr. E. A. SALZEN

West African Fisheries Research Institute, Freetown

PART of the work of the West African Fisheries Research Institute is to explore the whole of the West African continental shelf for potential trawling grounds, and to determine the nature and extent of such grounds for possible future exploitation. A recent survey with the F.R.V. *Cape St. Mary*, a 100-ft. diesel trawler, of the continental shelf off Tema in the Gold Coast gave results which are of considerable interest because of their similarity with those obtained by Postel[1] working off French Guinea. Yet these two areas are a thousand miles apart and the French Guinea shelf is more than 70 miles wide compared with 14 miles at Tema. It may be, therefore, that the results for Tema are typical of a great deal of the West African shelf in the dry season.

The survey covered the whole of the shelf for 20 miles on either side of the port of Tema. Twenty-eight stations in depths of 10, 20, 30, 50, 100 and 200 fathoms were distributed in five transects at eight-mile intervals along the shelf. Fifty-eight hauls were made, mostly of one hour duration. One day and one night haul were made at each 10–50 fathom station, and one day haul was made at each 100 and 200 fathom station with hauls of 2-hr. duration at the latter depth. All the hauls were made with the same gear (Peter Carey trawl, 72 ft. head-rope, 10 ft. legs, 15 fathom sweeps and Dan Lenos with rollers), towed at the same engine speed but in varying relation with the direction and speed of the tide. Three hauls were made at each station on one of the transects in order to obtain a measure of the variance in rate of catch for the same ground. This showed that the variance and mean rates of catch for different stations at the same depth did not differ significantly from the variance and mean rates of catch for repeated hauls at the same station and same depth. This suggests that the fish population in the Tema area does not vary along the shelf.

The results for the hauls were, therefore, grouped according to depth. The rates of catch for the various depths and for day and night trawling are shown in Table 1. They are comparable with rates of catch obtained by Whiteleather and Brown[2] in the Gulf of Paria and off British Guiana, and with fishing in Australian waters reported by Houston[3] and Fairbridge[4]. They are better than the results obtained off Bombay by Hefford[5] and on the Patagonian shelf reported by Hart[6]. The changes in rate of catch with increasing depth are very similar to those found by Postel for the French Guinea shelf. The correspondence between this region and the Tema area extends to the nature of the bottom and to the nature and distribution of the fish species, the same species occurring at the same depths in both areas. Postel found a distinct change from euryhaline and eurythermal species in the shallow inshore water, to red and brown marine species below 10 fathoms. The results for the Tema area show the same change involving the same species. In addition, as can be seen from Table 2, there is a more subtle change in species which takes place from 20 to 100 fathoms. The predominant species change with depth, and this is a very important change from the fishery development point of view because the species become of smaller average size and lower commercial value with increasing depth. At 200 fathoms the fauna appears poor and abyssal in nature, with a few coryphenids and stomiatids.

Table 1. RELATION BETWEEN RATE OF CATCH AND DEPTH FOR DAY AND NIGHT TRAWLING

Depth in fathoms	Day fishing		Night fishing	
	No. of hauls	Rate of catch kgm./hr.	No. of hauls	Rate of catch kgm./hr.
10	10	98·6	5	127·9
20	7	78·4	6	156·6
30	8	69·6	4	94·6
50	5	46·5	4	97·0
100	5	103·5	—	—
200	2	1·4	—	—

Table 2. DISTRIBUTION WITH DEPTH OF THE PREDOMINANT FISH SPECIES IN THE TEMA AREA

The table shows the number of hauls in which more than 1 kgm. of the species occurred expressed as a percentage of the total number of hauls at that depth. The species are therefore the ones which are of economic importance

* Non-marketable species

The correspondence between the Tema area and the French Guinea shelf poses the question as to whether the same description will hold for the greater part at least of the West African shelf. An extensive trawling and hydrographic survey of the region, from Dakar to the Cameroons, was made by the *Cape St. Mary* during 1952–53. The results of this survey, though not very detailed, tend to support such a generalization. The eurythermal and euryhaline fish fauna inshore of the 10-fathom line suggests that the water of this region is subject to fluctuations in temperature and salinity, probably as a result of heavy rainfall and freshwater run-off from the land. It is interesting to note that both the extent of this region and the rainfall are smaller in the Gold Coast than in French Guinea. The inshore region of French Guinea (Postel[7]) and indeed of much of the West African coast (unpublished results of the *Cape St. Mary* cruises, 1952–53) is greatly affected in salinity and temperature in this way. Currents and upwelling may be important modifying factors because of their mixing action. In their absence, stratification with its usual adverse affect on the fauna would tend to occur. It is possible, therefore, that heavy rainfall and freshwater run-off from the land are important factors, though not necessarily the only factors, in determining the nature and distribution of the inshore fish fauna of West Africa.

I wish to thank the Director of this Institute for permission to publish this work. A full account will be published elsewhere.

MODIFICATIONS OF MICROSCOPIC TISSUE REACTIONS TO HOMOLOGOUS GRAFTS IN RABBIT PARABIONTS

By Dr. RICHARD H. ANDRESEN, Dr. CLARENCE W. MONROE, DOROTHY A. MADDEN and Dr. GEORGE M. HASS

Rush Departments of Pathology and Surgical Research, Presbyterian Hospital, Chicago, Illinois, in affiliation with the University of Illinois College of Medicine

PREVIOUS investigations using musculofascial transplants have led to an accurate means for distinguishing between autografts and homografts by a microscopic study of the tissue reactions at the site of grafting. Though the musculofascial transplants did not survive permanently, they were suitable for our purposes for the following reasons: (1) resection and implantation could be done under strict aseptic conditions; (2) the grafts were simple in structure; (3) tissue for grafting was available in large amounts; (4) the transplants were sufficiently uniform so that they could be fractionated by available chemical methods without much variation in the composition of the fractions.

New Zealand rabbits of the same source and strain were used. Autografts and homografts of erector spinæ muscle were regularly made to sites comparable with those from which the grafts were resected[1]. After the first week, transplants were well healed in place. Thereafter, gradual organization and resorption ordinarily occurred so that by the end of three or four weeks most of each type of transplant had disappeared. On this account, microscopic study of host–graft reactions at sites of transplantation were most satisfactory at the end of the second week. At this time autologous transplants were well healed in place. A bursal space had formed immediately over the transplant and just beneath the superficial fascia of the skin of the back overlying the transplantation site. A pannus of vascularized granulation tissue regularly grew over the fascia of the transplant forming the base of the bursal space. The fascia of the transplant was œdematous and thickened, presumably due to retraction. Vascular channels arising from the host and growing along with the pannus penetrated the fascia perpendicularly and ramified in the musculofascial zone. As vascularization occurred, the musculofascial zone became broad and filled in with a plexus of small vascular channels supported by proliferating fibroblasts and newly formed collagenous fibrils, which occupied the zone vacated by the resorption of subfascial skeletal muscle. Infiltration of inflammatory cells was negligible in the autologous grafts.

Microscopic study of homologous musculofascial transplants, two weeks of age, showed that patterns of degeneration and resorption of muscle with organization of the musculofascial zone began in much the same way as in the autologous transplants. However, there were factors in the host–homograft relationship which interfered with the successful completion of the autologous pattern of resorption and organization. These factors led to a massive infiltration of lymphoid cells into the musculofascial zone. This infiltration was accompanied by a variable amount of angiitis affecting small vessels within the pannus, fascia and musculofascial zone of the transplant. These microscopic findings allowed us to distinguish accurately between homologous and autologous transplants.

Although the above response which was designated as the basic homologous host–graft tissue reaction was characteristic of the microscopic response to an initial transplant, the nature of this reaction changed when multiple, successive transplants of musculofascial tissues to the same host were made from the same donor[1]. This change consisted of an acute thrombotic necrotizing reaction with hæmorrhage involving especially the musculofascial zone of the second and third transplants in succession. In connexion with this acute reaction, there was conspicuous impairment of fibroblastic proliferation and formation of collagen. Infiltration of lymphoid cells was also reduced, and most cells in the musculofascial zone were eosinophiles and polymorphonuclear leukocytes. This form of reaction was designated as an acute 'sensitized' homologous host–graft tissue reaction.

In an attempt to discover factors responsible for the basic and sensitized homologous host–graft tissue interactions, it seemed desirable to study the effect on the interactions of exposure of musculofascial transplants to X-irradiation and thermal treatment *in vitro* prior to transplantation[2]. These studies disclosed that by sufficient exposure either to X-irradiation at high and low temperatures, grafts could be so modified that the microscopic host–autograft and host–homograft interactions were identical. The observations also led to the conclusion that the customary host–graft interactions appeared to depend to a large extent upon the mutual admixture of proliferating vascularized mesenchymal tissues of the graft and the host. Anything which impaired the rate of proliferation or the admixture of the tissues seemed to impair the intensity of the homologous or autologous reactions. Indeed, the classical autologous and homologous reactions both disappeared when the thermal and irradiation treatments were sufficient to eliminate the stimulus to admixture, despite prolonged persistence of the grafts in the host.

In view of the apparent significance of the activity of the cells of the host, as well as those of the graft, it was decided to study the reactions which occurred between surgically united homologous tissues, each retaining its own blood supply. For this purpose, rabbits were joined surgically by the ears[3]. Within three to four days after surgical anastomosis, continuity of circulation between the two animals was demonstrated and the dermal epithelium of the parabionts was also united. Furthermore, collagen and reticulum were mutually deposited at the site of anastomosis so that a firm connective-tissue union between the two ears was established. After seven to thirteen days, it was no longer possible to demonstrate a cross-circulation; and its failure to persist was correlated with the development of an inflammatory reaction along the plane of anastomosis of the tissues. During this time the united dermal epithelial surfaces of the parabionts also became discontinuous. The infiltration of lymphoid cells and the angitic reactions on each side of the plane of anastomosis persisted almost unchanged for as long as five months in some animals even though the mesenchymal tissues remained firmly united by persistence of collagen and reticulum which had been deposited during the early stages of healing[4]. The question arose as to whether the persistent collagen and reticulum belonged specifically to each animal or whether the intercellular products resistant to the incompatibility reaction were a third compatible form of tissue developed by the joint activities of cells and fluid substrates of the two animals.

With the experience of repeated musculofascial grafting and the resultant sensitized reactions in mind, pairs of parabionts were separated and then reunited in parabiosis by surgical anastomosis of the two other ears. In these instances the aural junctions failed to heal and separated spontaneously on the fifth or sixth day after anastomosis. This was regarded as another form of sensitized homologous incompatibility reaction, for when a parabiont was united to a control animal which had never been in parabiosis, healing of the ears occurred in much the same way as between two control animals. These observations indicated that it might be profitable to make a microscopic study of the host–graft interactions to musculofascial grafts following parabiosis rather than to use inbred strains of animals in successful parabiosis, as had been done in a study of renal grafts[5]. Therefore, rabbits were united in parabiosis for periods of two to three weeks and then separated from one another. One group was reunited in parabiosis a second time and then separated a second time. Another group was placed in parabiosis but once. Animals in both groups were then cross-transplanted with musculofascial grafts derived from their respective parabiotic twins. The grafts and adjacent tissues showed two types of host–graft interactions which were about equally distributed between the two groups of parabionts. The first type consisted of a fibro-collagenous encapsulation of the transplant with excellent preservation of the architecture of the graft. There was no penetration of the graft by vascularized mesenchyme from the host.

The second type of reaction was similar to the first, except that vascular penetration of the graft by vessels arising in the tissues of the host occurred, often developing a strange angiomatous pattern of large patent channels which ramified throughout the fascia and subjacent musculofascial zone of the transplant. Despite the conspicuous vascularization, the musculofascial zone of the transplant was not materially modified because fibroblastic proliferation, collagen formation and inflammatory reactions did not occur. In other words, the characteristic features of either the basic or sensitized homologous host–graft interactions did not develop. The parabiotic response was very specific and was readily reproduced between parabiotic twins after separation for as long as ninety days. However, if cross-transplants were made between parabionts which had never been joined together, the incidence of the parabiotic type of host–graft interaction was reduced about one-half. When the musculofascial transplants to parabionts were obtained from animals which had never been in parabiosis or exposed to grafting procedures of any kind, the types of host–graft interactions at the site of transplantation in the parabiont were variable and unpredictable. These studies, however, did show that the parabionts retained the capacity to react with the classical homologous types of response to tissues derived from animals which had never been in parabiosis or subjected to free grafting procedures.

Further permutations of musculofascial grafts between control and post-parabiotic animals have indicated that about one-third of the control rabbit population falls into a class characterized as follows. If the parabiont reacted to the transplant from the control animal with a parabiotic type of reaction, transplants to the control animal from the parabiont were accepted by the control animal with an autologous-like tissue reaction. In other words, the parabiont's musculofascial tissues were almost as acceptable to the control animal as similar grafts from the control animal into itself. This observation led us to consider the possibility of carrying out successful homologous transplants with the assumption that by use of post-parabionts and non-parabionts a beginning has been made in developing a means for placing genetically impure strains of rabbits in groups according to their tissue types.

This study was supported by funds from the National Heart Institute, National Institutes of Health (*H*-1630), the Muscular Dystrophy Associations of America, Inc., and the Otho S. A. Sprague Memorial Institute.

METHOD OF MOLECULAR FIELDS

By T. M. DUNN

William Ramsay and Ralph Forster Laboratories, University College, Gower Street, London, W.C.1

THE applications of ligand field (crystal field) theory have brought about a great deal of clarification in the realm of the magnetism, structure and spectra of inorganic transition metal complexes, mainly of the spin-free type. In this method the inorganic ion is placed in an electric field of suitable symmetry and the changes in the free ion energy-levels resulting from the Stark splitting of the free space five-fold degeneracy of the *d*-electrons are calculated.

The Stark field is supplied by a system of negative ions or by dipoles oriented with negative poles towards the positive ion, and under the perturbation thus caused the 'non-bonding' *d*-electrons of the ion assume the position of lowest potential. In a cubic field this perturbation causes a split of the *d*-levels into the now familiar essentially non(σ)bonding $d\varepsilon$ triplet, which decreases in energy, and the essentially non- or anti-bonding $d\gamma$ degenerate pair, which are shifted to higher energies.

It is important to point out that this general type of approach can be applied with equal success to elements in the periodic table prior to the first transition series, where the spin-paired behaviour is the rule rather than the exception. In its application to this class of compounds the term ligand, or crystal field, theory has little significance and is rather misleading so that it is suggested that the theory be called the method of molecular fields.

The essential difference between the approach in this case and in the ligand field theory consists in the use of positive charges as the origin of the perturbing Stark field. Positive charges are used because any atom in a spin-paired molecule acts towards its near neighbour as a source of positive potential, attracting electrons towards itself rather than repelling them as in the ligand field theory.

Consider the case of acetylene. As a first approximation we may consider a carbon atom at the origin of a set of Cartesian co-ordinates with unit positive charges at $(0,0,a)$ and $(0,0,-a)$, that is, along the z-axis.

Since no electric field can remove a Kramers two-fold degeneracy it is only the $2p$ orbitals which split in the linear Stark fields. This triply degenerate $2p$-level splits to give a low-lying singlet and a high-lying doublet. This splitting is indicated in Fig. 1.

It is easy to see even intuitively that the p_z orbital is the one depressed to lower energies and so its energy becomes much more compatible with the $2s$ atomic orbital.

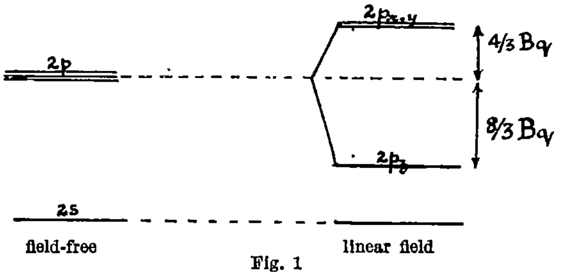

Fig. 1

The four electrons can now be fed into the levels and the configuration will depend upon the magnitude of the p splitting. Thus, if the splitting is large, then the configuration will be (ignoring the $1s$ electrons) $2s^2\ 2p_z^2$, giving a $^1\Sigma_g^+$ state.

This can also be shown for the states of the free carbon atom subjected to a very strong Stark field. The atomic states arising from the configuration s^2p^2, namely, ^3P, ^1D and ^1S, are split by the field as follows. The lowest atomic state ^3P is split into a pair of states $^3\Sigma_g^-$ and $^3\Pi_g$ (in $D_{\infty h}$ notation), ^1D gives rise to a low-lying $^1\Sigma_g^+(1)$ state and two higher lying states $^1\Pi_g$, $^1\Delta_g$, and the ^1S is not split but is now designated $^1\Sigma_g^+(2)$ (Fig. 2).

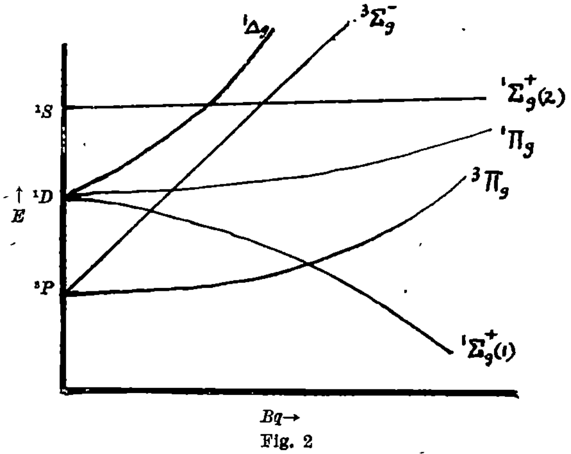

Fig. 2

If the field is not too strong then the $^3\Pi_g$ state will lie lowest and the configuration will be $2s^2\ 2p_z\ 2p_{x,y}$. In this case the excitation of an s electron to the $p_{x,y}$ shell will produce, among other configurations, a carbon atom with four parallel spins, the difference from the usual sp^3 configuration being that the p orbitals are no longer equivalent.

The solution of a perturbation secular determinant for the s- and p_z-levels will yield the familiar sp digonal or linear hybrid orbitals and these may be occupied by replacing one of the positive charges by a hydrogen atom with opposite electron spin to the bonding sp electron. The other positive charge may be replaced by a similarly constituted CH group also with opposite sp bond electron spin. Provided also that the p_xp_y electrons on the two CH groups are opposite in spin, then the two π bonds will form and complete the acetylene molecule.

The analogous case of ethylene can be similarly considered by using a plane trigonal array of positive charges in the x,y plane, when it is easily shown that the p_x and p_y energies fall and the p_z rises as in Fig. 3.

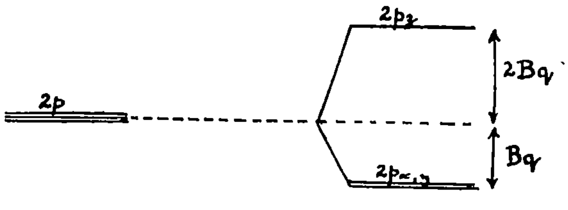

Fig. 3

The further splitting of the levels during 'covalent' or spin-paired molecule formation has been ignored in this preliminary discussion but can be included without altering the final results. The theory also shows that in the case of the tetrahedral carbon atom there is no splitting of the p shell and so all p orbitals are equivalent.

One important feature of this description is an added reason for the relative success of the σ–π electron approximation. The Huckel approximation thus owes part of its success to the differences in energy of the σ and π shells which develop under the influence of the Stark perturbation as well as the differences in symmetry of the shells, since electrostatic perturbations will be less effective in mixing orbitals with greatly differing energies.

In π electron calculations it is not usual to minimize the energy with respect to the effective potential of the carbon nucleus for each problem, and the value of Z^* usually used is that due to either Zener (3·18) or the Slater value (3·25). The above considerations suggest that this value is too high and that a lower value would lead to more correct estimates of the π energy in the absence of a complete calculation.

Bayliss directed attention to this fact[1] in 1949 when he pointed out that if the π energy of butadiene was minimized with respect to the effective potential field of the carbon atom using a free electron model then the value of Z^* was 1·2. This is perhaps too low an estimate but shows the correct trend. The molecular field correction to the Z^* value for π calculations is reduced somewhat when the effect of resonance splitting during molecule formation is taken into account.

The splitting magnitude to be expected for the p shell may be calculated theoretically in terms of a parameter Bq (analogous to the parameter Dq in ligand field theory) which can also be calculated theoretically. It seems more desirable at first, however, to consider Bq as an adjustable parameter which once obtained can be applied to other cases of interest. Reasonable estimates of Bq result in a value of the order of 1 eV, thus giving an overall split in the acetylene p energy-levels of about 3 eV.

The method of molecular fields is not limited in its application to first- and second-row elements but can be applied to the transition series of metal spin-paired complexes, as an example readily shows.

In the case of octahedral spin-paired complexes such as potassium ferricyanide the situation is that instead of negative charges surrounding the central ion at points along the co-ordinate axes, the perturbing potential is assumed to be, in addition, a *pair* of positive charges situated above and below the ligand co-ordinates. This is simply because if CN is used as ligand (*not* CN^-) it can be reasonably supposed that the effect of the positive ion on the ligand will be to lower the energy of the $x\sigma$ antibonding orbital relative to the $w\pi$, and this can be regarded as leading to a hole in the π shell with a completed σ shell. This results in a tendency for the $d\varepsilon$ shell to become stabilized by two methods which cannot be strictly resolved: (1) The attraction of $d\varepsilon$ electrons into the π shell of the ligand; (2) the repulsion of the $d\gamma$ electrons by the lone σ pair of the CN group.

Thus, in the case of these spin-paired complexes the push-pull operation of these two factors results in a very large splitting compared to the spin-free complexes.

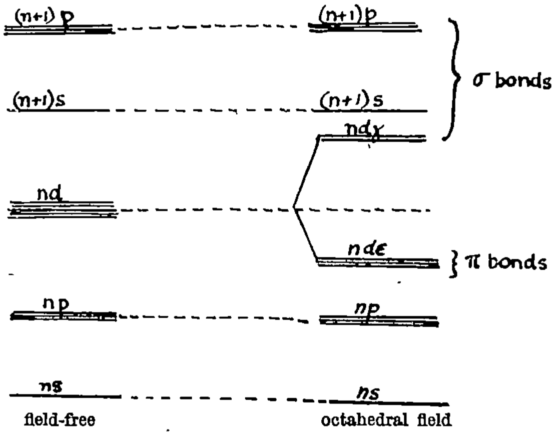

Fig. 4

In this way the $nd\gamma$ orbitals of the central ion become comparable in energy with the $(n+1)s$ and $(n+1)p$ atomic orbitals of the ion as well as with the σ lone pairs of the ligands and so effective overlap can occur. The complete scheme is shown in Fig. 4 and shows one reason why the calculations of Craig *et al.*[2] showed a disappointingly small overlap of nd with $(n+1)s$ and $(n+1)p$.

The full details of the calculations, together with wider applications of the theory, will be published shortly. [Sept. 26

A Microchemical Method for the Preparation of Sources of Actinium and Europium for β-Ray Spectroscopy

The preparation of adequate sources is one of the most critical problems in β-ray spectroscopy. In general, chemical means alone have not proved sufficient. Crystal formation and the tendency for a non-uniform distribution of the source material make the effective thickness of the source considerable, even in cases where the amount of material is small enough to make the average thickness negligible. In addition, it is often difficult to concentrate the activity on a sufficiently small area of the supporting foil. For these reasons, use has been made of evaporation *in vacuo*, of electrolysis, and of isotope separators.

The method to be described here is nevertheless a purely chemical one. It has the advantage of high efficiency, and potentially the advantage of general applicability. We believe that the procedure described for actinium and europium can be applied with little modification to the thirty lanthanides and actinides. We also see no reason why in principle the procedure cannot be utilized with the same or other resins to concentrate many of the seventy remaining atomic species, provided they are in an essentially carrier-free form.

The basic principle is the concentration of the activity on a very small ion-exchange column and the subsequent elution with a strong eluting agent to get out the activity in a very small volume.

Actinium-228, a 6-hr. beta minus emitter, is used as an example in the procedure which follows. The initial actinium sample (volume 0·3 c.c., activity 10 μc.) is a carrier-free solution of 5 per cent ammonium citrate (*p*H 4·3) obtained by ion-exchange separation of actinium-228 from its long-lived mother substance, radium-228, the ion exchanger being 'Dowex 50'. Concentrated hydrochloric acid is added to adjust the *p*H to about 1 ; that is, the citric acid is largely brought to its undissociated form and hence actinium will exist as Ac^{3+} :

$$\mathrm{Ac(H\,Ctr.)_2^-} + 4\mathrm{H}^+ \rightarrow \mathrm{Ac}^{3+} + 2\,\mathrm{H_3Ctr.} \qquad (1)$$

The sample is now forced through a 'Dowex 50-*X*12' column which has previously been conditioned in order to bring it either to the hydrogen or to the ammonia form. Although the particle-size of the resin may be varied within limits, the particles of the resin used in most of our experiments have a settling rate in water of 0·3–0·5 cm./min. The column dimensions are 0·03 mm.^{2} by 13 mm., the free column volume thus being 0·2 μl. Even when the actinium is forced through at a flow-rate in excess of 10 μl./min., more than 80 per cent of the activity remains with the resin (*R* denotes resin skeleton):

$$\mathrm{Ac}^{3+} + 3R\mathrm{SO_3NH_4} \rightarrow (R\mathrm{SO_3})_3\mathrm{Ac} + 3\,\mathrm{NH_4}^+ \qquad (2)$$

Finally, the column is eluted with a 1 *M* ammonium lactate solution (*p*H 5–7) :

$$(R\mathrm{SO_3})_3\,\mathrm{Ac} + 3\ \mathrm{Lact.}^- \rightarrow 3R\mathrm{SO_3}^- + \mathrm{Ac\ (Lact.)_3} \qquad (3)$$

The activity comes out with the front of the eluent in a volume of 0·5–2 μl. This small volume is picked up on a 150-μgm./cm.^{2} aluminium foil and dried under an infra-red lamp. The foil, which has previously been fastened on a 0·5-mm. metal frame with the aid of a minute amount of 'Zapon' lacquer, is now transferred to a crucible and heated with a Bunsen burner. The ammonium lactate evaporates leaving the activity on an area of 1–3 mm.^{2} in a very thin and quite uniform layer which is often invisible. The overall yield is, apart from decay, 30–80 per cent. The procedure takes 2–3 hr. The effective thickness of the source has been estimated from the resolution of internal conversion lines in the low-energy region (< 50 keV.) (see Fig. 1). Comparison with the internal-conversion lines resulting from isotope-separated activities in which the ions have been driven into the aluminium backing to a depth of approximately 5 μgm./cm.^{2} indicates that equally thin sources can be obtained with the present method.

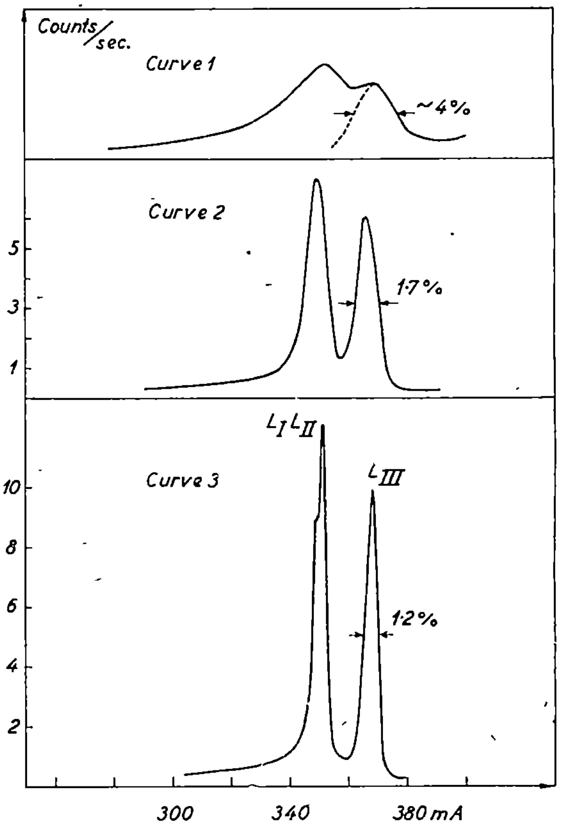

Fig. 1. $L_I L_{II}$ (37 keV.) and L_{III} (41 keV.) conversion lines of the 57-keV. *E*2 transition in thorium-228 measured in a β-ray spectrometer with sources of different thickness

The most serious difficulty in connexion with the method arises from the fact that impurities will also be concentrated by processes (1), (2), and (3). This is true for alkaline earths, particularly calcium and magnesium, and third-group metals, particularly aluminium. The ion-exchange separation which precedes the concentration procedure just described is not specifically worked out in order to eliminate impurities. If as an example we assume an ash content of 10 p.p.m. by weight in the initial 0·3-c.c. sample, this results in a mean thickness of 100 μgm./cm.^{2} when spread over a 3-mm.^{2} area. The effective thickness would presumably be considerably greater (Fig. 1, curve 1).

We have overcome these difficulties by using 'Dowex-50' ion-exchanged reagents. This greatly decreases the thickness of source while maintaining a yield as high as 80 per cent (Fig. 1, curve 2).

A further improvement can be achieved by using a weaker eluent in process (3). If, instead of a 1 *M* ammonium lactate solution, one uses a molarity of 0·7, an actual separation takes place on the micro-column between the ash and the activity. However, this happens at the expense of the yield, which decreases to 30–50 per cent, apart from decay. Also the time required for preparation of the source is increased to three hours. Curve 3 (Fig. 1) shows the maximum resolution obtained from a source made in this way.

The procedure has also been successfully applied to the preparation of a source of europium.

We wish to thank Prof. Niels Bohr for the ideal working conditions in his Institute, Prof. I. Perlman for discussions and for some of the graded resin used in these experiments, and Prof. K. Linderstrøm-Lang and Mr. Sigurd Olaf Nielsen for valuable suggestions with respect to microtechniques.

High-Resolution Microwave Zeeman Spectrometer

A HIGH-RESOLUTION microwave Zeeman spectrometer has been constructed, and measurements of molecular magnetic moments are now being made on a series of molecules.

The apparatus is similar in principle to that described by Jen[1]. A resonant-cavity absorption cell is located between the poles of a large electromagnet. A *Q*-band klystron the reflector of which is modulated simultaneously by a 25-c./s. saw-tooth voltage and a 100-kc./s. sine-wave supplies power to the cavity at a frequency of ∼ 35,000 mc./s. The power reflected from the cavity is detected by a silicon crystal, amplified and displayed on one trace of a double-beam oscilloscope, the time-base of which is the source of the 25 c./s. saw-tooth modulation.

The gas under investigation is let into the cavity at a pressure of a few microns, and when the klystron frequency and modulation index, the power-level and the crystal detector unit have all been correctly adjusted, the appropriate rotational absorption line is displayed (Fig. 1). This line splits into two (or more) components when the magnetic field is applied (Fig. 2).

To facilitate the initial adjustments a 3-metre wave-guide absorption cell is simultaneously employed. The signal from the crystal at the output end of this cell can be switched on to the first oscilloscope trace in place of the cavity-resonator signal. Power from a second klystron the reflector of which is modulated at a variable radio frequency of ∼1 Mc./s. is mixed with that of the first, and the difference-frequency spectrum detected by a 30-mc./s. frequency-modulated receiver. The output of this receiver is applied to the other beam of the oscilloscope, and consists of a ladder of sharp marker pulses the spacing of which, on a frequency base, is the modulation frequency of the second klystron. Frequency difference of lines displayed on the first oscilloscope trace can thus be measured by superimposing the markers displayed on the second trace (Fig. 3).

The wave-guide cell and the cavity cell can be heated or cooled to 'dry-ice' temperature, and in this way the intensities of the absorption lines increased.

For the $J,K = 13,13$ line in the ammonia inversion spectrum, we have verified that the temperature dependence of the line intensity is of the expected form $\alpha T \equiv A \exp(-B/T)$, where α is the line intensity, T the absolute temperature and A and B constants for the line[2].

The magnetic field is measured with a nuclear magnetic-resonance field meter, which is also used for field stabilization.

Thus the Zeeman effect is measured in terms of two radio frequencies—that of the signal generator modulating the second klystron, which measures the Zeeman splitting, and that of the nuclear magnetic resonance oscillator, which measures the magnetic field. Both frequencies are calibrated in terms of an accurate crystal-controlled wave-meter. The spectrometer has been used for measuring the Zeeman splitting (σ-transitions) of four lines in the $^{14}NH_3$ inversion spectrum, namely:

$J,K = 12,12$ at 31,424·97 Mc./s.
$J,K = 13,13$ at 33,156·95 Mc./s.
$J,K = 14,14$ at 35,134·44 Mc./s.
$J,K = 15,15$ at 37,385·18 Mc./s.

Because of the large quantum numbers, the hyperfine structure due to the ^{14}N quadrupole coupling cannot be resolved, and the Zeeman splitting yields the molecular magnetic moment directly.

The Zeeman splitting of these lines is linear up to the highest magnetic fields so far applied, namely, 0·5 weber/metre².

The same molecular g-factor is obtained for all four of these lines, within the limits of error of approximately ± 2 per cent.

The mean of all the measurements on the four lines is $g_{\text{mol.}} = 0{\cdot}490 \pm 0{\cdot}008$. With the values of $g_{xx} = 0{\cdot}560$ and $g_{zz} = 0{\cdot}484$ obtained by Eshbach and Strandberg[3] from measurements of seven ammonia lines in the region $J,K = 3,1$–$6,6$, an effective molecular g-factor, $g_{\text{mol.}} = 0{\cdot}490 \pm 0{\cdot}007$, should be expected for the J-values used in our measurements, provided that g_{xx} and g_{zz} are independent of J.

The close agreement shows that this condition holds over the whole range of rotational-levels so far

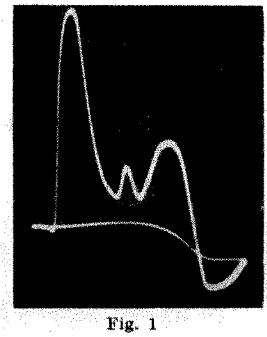

Fig. 1

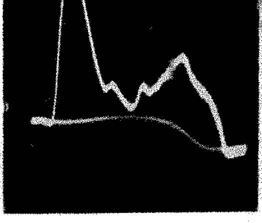

Fig. 2

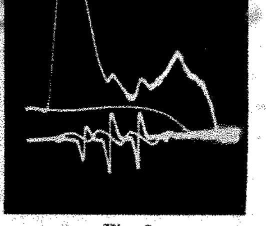

Fig. 3

observed, and implies that there is no significant dependence of valence electron 'slip' upon the angular momentum of the molecule.

From the Zeeman splitting of the $K = 1$ component of the $J = 1 \rightarrow 2$ doublet in the spectrum of CH_3CCH, we have obtained $g_{zz} = 0{\cdot}30 \pm 0{\cdot}02$, in close agreement with the values found by Cox and Gordy[4] from the $J = 2 \rightarrow 3$ and $J = 3 \rightarrow 4$ transitions, namely, $g_{zz} = 0{\cdot}298 \pm 0{\cdot}006$. In agreement with Cox and Gordy, we find no observable splitting of the $K = 0$ component, that is, $g_{xx} \approx 0$.

Combustion of Methane

It is known that the most reactive mixture of methane and oxygen is $2CH_4 + O_2$, the most easily detonated $CH_4 + O_2$ and the most inflammable $CH_4 + 2O_2$. Methane is not unique in this respect because, as Coward and Payman[1] have pointed out, the most reactive mixtures of each of the simple paraffin hydrocarbons with oxygen are those containing hydrocarbon and oxygen in the molecular proportion 2 : 1; yet none of these mixtures can propagate flame at normal temperature and pressure. An interpretation of these curious facts may be suggested on the following lines.

The 2 : 1 ratio of methane to oxygen in the most reactive mixture implies that the determining step in the slow combustion of methane involves two molecules of methane and one of oxygen. (The word step is used in the thermodynamic, not the kinetic, sense. That is, we are concerned with equilibrium states, not the route from one to the other.) The slowness of the reaction is probably indicative of the low frequency of three-body collisions involving specifically two molecules of methane and one of oxygen. Its easy initiation, on the other hand, argues that relatively little energy is needed to disturb the equilibrium of this tri-molecular grouping and enable it to pass into the next equilibrium state. The simplest rearrangement would appear to be the splitting of the oxygen molecule, which must always happen, and the assimilation of one oxygen atom by each methane molecule. Thus,

$$CH_4 + (O + O) + CH_4 \rightarrow 2CH_3OH \ + \ 78 \text{ k.cal.}$$

This initial formation of methanol fits in with Bone's[2] scheme for the slow oxidation of methane.

The fact that the equimolecular mixture of methane and oxygen is the most readily detonated suggests that the initial step here is a two-body collision process involving one molecule of each kind. The products of the detonation reaction[2] are $CO + H_2 + H_2O$ and so it may be inferred that the determining step in the detonation of methane–oxygen mixtures can be represented thus:

$$\begin{aligned} CH_4 + O_2 &\rightarrow (C + H_2 + H_2) + (O + O) \\ &\rightarrow CO + H_2 + H_2O \qquad + 77 \text{ k.cal.} \end{aligned}$$

Hence the methane molecule also divides and, since three new molecules are formed, it must divide into three. This implies that much more energy per mole is required to trigger detonation than slow combustion.

The optimum proportions in the case of deflagration seem at first sight to suggest a three-body collision process involving one molecule of methane and two of oxygen; but this is statistically improbable in view of the speed of this reaction. The alternative would appear to be two successive bi-molecular encounters involving first one oxygen molecule and then the other. The first event, however, must be distinguished from detonation and, since deflagration is easier to initiate, it is reasonable to suppose that, in this case, the methane molecule divides into two instead of three. In other words, the methane molecule is stripped of one hydrogen pair instead of two. This may be represented:

$$\begin{aligned} CH_4 + O_2 &\rightarrow (CH_2 + H_2) + (O + O) \\ &\rightarrow CH_2O + H_2O \qquad + 78 \text{ k.cal.} \end{aligned}$$

followed by:

$$\begin{aligned} CH_2O + O_2 &\rightarrow (CO + H_2) + (O + O) \\ &\rightarrow CO_2 + H_2O \qquad + 135 \text{ k.cal.} \end{aligned}$$

The second stage of the reaction will, of course, benefit from the energy released in the first and may require no other help to initiate it, in which case the second stage follows spontaneously. Thus the activation energy of the whole process may correspond to that of the first stage whereas the total energy released is the sum of the two, namely, 213 kcal. per mole of methane.

The interesting point emerges that the energy released in detonation may represent only part of the total energy available and may in fact be much less than that generated by deflagration. The violence of the detonation process thus appears to be due more to the speed of the reaction than to the amount of energy released, and this depends on the statistical frequency of encounters between the appropriate species. This probably explains why the maximum detonation velocity in mixtures of methane and oxygen occurs not in the stoichiometric but in the equimolecular mixture.

Use of Irradiated Polymers as Initiators of Polymerizations

It has been demonstrated by physical methods[1] that in some polymers free radicals are formed during exposure to high-energy radiations, and that in some cases they can survive for long periods. These radicals can also be detected by chemical methods, and under suitable conditions they can be used for initiating the polymerization of typical monomers to give graft co-polymers[2]. In the preliminary work described here the formation of graft co-polymers has been detected by using a monomer labelled with carbon-14; by this means it has been possible to determine accurately very small weights of grafted material.

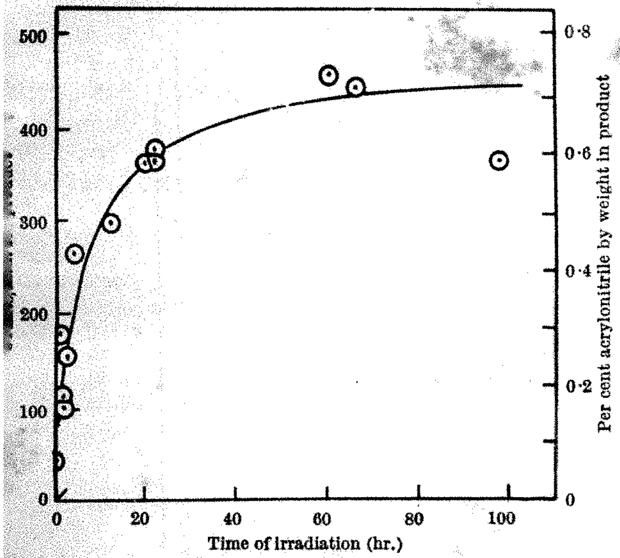

Fig. 1. The variation in activity and composition of the polymer with the time of irradiation, for 60 min. exposure to ^{14}C-acrylonitrile vapour at a pressure of 78–79 mm. mercury; samples at 18·5°–19·5° C. during exposure

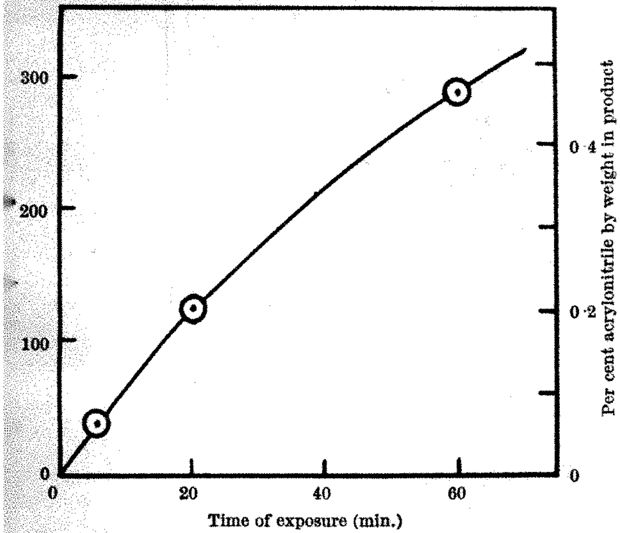

Fig. 2. The variation in activity and composition of the polymer with the length of exposure to ^{14}C-acrylonitrile vapour at 73·5 mm. mercury, for irradiation of 17 hr.; samples at 19·5° C. during exposure to monomer

Polymers, for example, polystyrene, polyacrylonitrile, 'Terylene' and 'Nylon', are irradiated in vacuum with γ-rays from a cobalt-60 source (nominally 100 curies). The irradiated polymers are afterwards exposed to the vapour of ^{14}C-acrylonitrile. After the residual vapour has been pumped off in high vacuum, the specimens are assayed by gas-counting. In some cases, as much as 10 per cent by weight of acrylonitrile is introduced into the polymer. Only a negligible amount of vapour is taken up by a sample which has not been irradiated. For example, two samples of powdered polyacrylonitrile were exposed to the vapour of ^{14}C-acrylonitrile at 78 mm. mercury for 2¼ hr.; the first had previously been irradiated for 18 hr., but the second had not been exposed to γ-rays. The first sample gave a counting-rate of 6,350 counts/min. whereas the second gave only 81 counts/min.; the counting-rate for polymer prepared directly from the labelled monomer was 59,300 counts/min.

With 'Nylon', the same results are obtained when the specimen is exposed to ^{14}C-acrylonitrile vapour 100 hr. after irradiation as when there is only a short interval after irradiation. If air is admitted to the specimen after irradiation, its activity is almost completely destroyed.

To obtain reproducible results, it is necessary to control carefully a number of factors, namely: (1) the physical state of the polymer, in particular its specific surface area; (2) the irradiation dose; (3) the time of contact with vapour of labelled monomer; (4) the pressure of the monomer vapour; (5) the temperature of the specimen during exposure to monomer.

Experiments with 15-denier monofil 'Nylon' yarn (kindly supplied by British Nylon Spinners, Ltd.) have shown that the quantity of ^{14}C-polyacrylonitrile formed increases with irradiation dose but approaches a limiting value (Fig. 1). With samples of 'Nylon' given the same dose, the amount of monomer taken up increases with the time of exposure to the vapour but it is not a linear function of the time (see Fig. 2 for typical results).

It is believed that free radicals at, or very near, the surface of the irradiated polymer act as centres for the polymerization of ^{14}C-acrylonitrile, and that polymer chains grow out from the surface of the irradiated material. If this is the case, the importance of the factors mentioned above can be understood. Work is in progress to elucidate the precise mechanisms of these reactions, and in particular to determine the number and average length of the branches grafted on the stock polymer.

The cobalt-60 source was installed by the Atomic Energy Research Establishment, Harwell. We thank the Department of Scientific and Industrial Research for a maintenance grant to one of us (D. E. E.) and Dr. H. W. Melville for his interest in this work.

Water Sealing of Detached Aluminium Oxide Anodic Film

The formation of boehmite on anodized and non-anodized aluminium surfaces by boiling-water treatment has been discussed by Hart[1]. He found by electron diffraction study of ammonium borate anodic films on aluminium that such treatment changed the quasi-amorphous structure of the coating to boehmite, whereas with films stripped from the metal this change did not occur. Hart suggested that the formation of boehmite was due to an electrochemical reaction in which aluminium ions from the aluminium base moved outward through the oxide film to meet hydroxyl ions and formed boehmite in the pores or on the outer surface. Application of this theory to sulphuric acid anodic coatings which are much thicker and more porous than the borate films is of interest since it is generally believed[2] that the formation of boehmite during boiling-water sealing of such coatings is due to hydration of the aluminium oxide.

Aluminium sheet (99·87 per cent) of 0·5 mm. thickness was anodized (15 per cent wt. sulphuric acid, 21° C., 1·6 amp./sq. dm., 60 min.) to form an oxide film approximately 0·030 mm. thick. The weight gain on water sealing (de-ionized water, 100° C., *p*H 6·1, 30 min.) of such coatings was determined. The film weight was determined by dissolution of the coating, in a chromic – phosphoric acid solution[3]. Panels anodized in a similar manner were sheared into 1 cm. × 2 cm. squares and the unsealed oxide film was detached from these by a modified Wernick[4] technique (5–10 gm. mercuric chloride/100 ml. ethyl alcohol). The detached films were rinsed twice in absolute methyl alcohol. The weight gain on water sealing of detached oxide film was determined and compared with that of the non-detached film.

Electron diffraction patterns were obtained on non-detached and detached oxide films, in both the unsealed and water-sealed conditions. (Only results of examination of exterior film surface are discussed. Interior surfaces (metal side) give indefinite amorphous patterns.) A 50-kV. intensity beam was employed in an *EMU*-type *RCA* electron microscope. In examining the detached films it was necessary to evaporate a thin coating of aluminium on to both the non-examined side of the film and the diffraction sample holder. The treated film and holder were bonded together by use of Wood's metal to make a unit with increased heat capacity. This minimizes the heating of the oxide by the electron beam, which otherwise affects the structure as shown by a marked change in the observed pattern. (Heating of samples in this manner might be a useful technique in studying dehydration of various aluminas.)

The weight gain on sealing the film, which was sealed after being detached (7·1 per cent), was in good agreement with the value obtained for the non-detached film (7·7 per cent). No ring diffraction patterns were obtained with unsealed coatings, either detached or non-detached. Clear boehmite patterns were secured for sealed films (Fig. 1), including those sealed after removal from the aluminium. The patterns were compared with standard *ASTM* X-ray data and with results given by others[5,6]. A steam-sealed (115° C., 30 min.) stripped coating was examined and gave a slightly clearer boehmite ring pattern than did the water-sealed films.

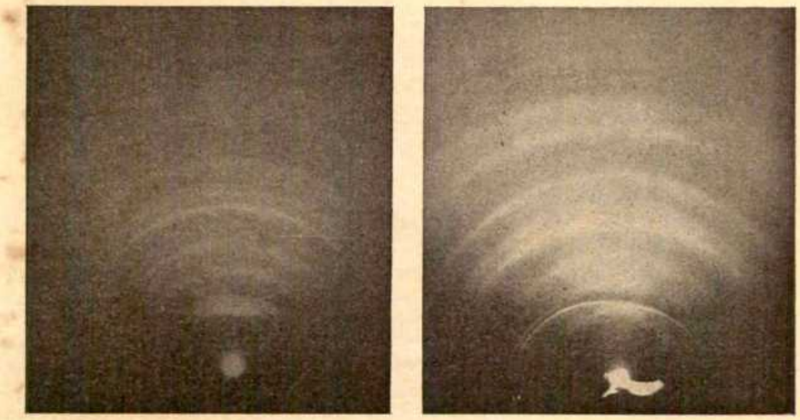

Fig. 1. Boehmite electron diffraction patterns of water-sealed sulphuric acid anodic films. Left, sealed on aluminium; right, sealed after removal from aluminium base

The similarity of the results obtained with films detached from their aluminium base to those for non-detached films confirms that water sealing of sulphuric acid type anodic films is a hydration process and does not require the presence of metallic aluminium.

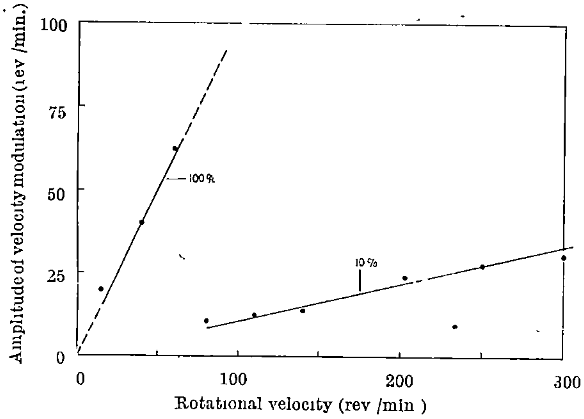
Torsional Vibrations of Rotating Shafts

A ROTATING shaft can exhibit torsional vibration when, because the dynamic coefficient of friction is less than the static value, the frictional force at the bearings supporting the shaft decreases as the shaft begins to rotate. The torque in the shaft when it begins to turn is greater than is required to overcome the running friction in the bearings, and the shaft accelerates and may overrun the drive until the speed of the shaft is reduced to zero. Then superposed on the steady rotation of the shaft there is a vibration of an amplitude such that the instantaneous angular velocity of the shaft varies between zero and rather more than twice the mean value. So-called 'stick-slip' vibrations of this type are well known—they may, for example, be responsible for brake squeal in automobiles.

With true 'stick-slip' vibrations the depth of modulation of the relative velocity of the two surfaces in contact is 100 per cent, and except when the mean relative velocity is very low, the frequency of the vibrations is determined primarily by the natural frequency of the system. Thus the amplitude of the velocity modulation of a vibrating shaft will be expected to increase linearly as the mean speed of the shaft is increased. In practice it is found that the amplitude increases in this way until a point is reached at which the vibrations suddenly cease. The transition does not occur at a fixed speed; but the chance of a system exhibiting 'stick-slip' vibrations decreases as the mean relative velocity of the surfaces in contact increases.

We have recently found, in experiments with a shaft of natural frequency about 25 c./s. and of diameter, at the bearings, of 0·625 in., that, on continuing to increase the speed of the shaft beyond the point at which 'stick-slip' vibrations ceased, the shaft vibrated at the same frequency but with an amplitude corresponding to a depth of modulation of only about 10 per cent. The behaviour of the shaft is shown in Fig. 1. In between the regions of



steady vibration with 100 or 10 per cent velocity modulation was a region of instability in which the shaft might run smoothly or might exhibit 'stick-slip' vibrations. The bearings were lubricated with a plain mineral oil, the conditions being such that a continuous oil film could not be maintained by hydrodynamic wedge action.

This small-amplitude vibration is believed to be associated with the time required for conditions in the bearings to come into equilibrium after a change in the velocity of the shaft.

Aluminium Molybdate and its Formation in Clay Minerals

The availability to plants of molybdate in some acidic soils may be increased by raising the pH. This behaviour of molybdate is analogous to that of phosphate, and suggests a study of its compounds with iron and aluminium, which are presumably responsible for holding molybdate in an insoluble form.

Unlike iron[1-3], aluminium has not been found as a naturally occurring molybdate. We have, however, prepared aluminium molybdates by precipitation from solutions of aluminium chloride and sodium molybdate. The precipitates have a Mo : Al ratio of 0·5, and have minimum solubility at pH 4·8. The temperatures of precipitation and digestion were varied, but no matter what these were over the range 20°–50° C. and 20°–90° C. respectively, the X-ray powder pattern and composition of the precipitates remained the same. The X-ray powder pattern consists of reflexions at 9·4 A. (weak), 4·78 A. (very strong), 3·25 A. (very weak), 2·44 A. (medium), 2·23 A. (strong), 1·99 A. (weak), 1·74 A. (strong), 1·46 A. (weak), and 1·35 A. (very weak). The material is highly hydrated and loses 34 per cent of its weight on heating to 800° C., and a further 17 per cent on heating to 1,000° C. The Mo : Al ratio suggests a basic salt; the formula $2(Al(H_2O)_4(OH)_2)MoO_4$ would agree with our analyses.

The aluminium minerals boehmite and halloysite are both found to adsorb large amounts of molybdate from solution over the pH range 4·0–5·5. At pH's above and below this range the amounts of adsorbed molybdate decrease sharply. These observations led us to examine the products obtained in the range of maximum adsorption. The minerals were therefore digested with sodium molybdate in aqueous suspensions at pH's 4·5–5·5 at 20° C. for 10 days, and soluble molybdate was then removed by washing. On examining the solid phases by X-ray diffraction it was found that two of the strongest reflexions in the powder pattern of aluminium molybdate (4·78 A. and 2·23 A.) had appeared in the boehmite and halloysite patterns. These reflexions cannot be attributed to any other material of which the X-ray powder pattern is known, and we may assume that molybdate has been chemisorbed and aluminium molybdate thus formed. This presumably is analogous to the formation of aluminium phosphates obtained on phosphating aluminium minerals[4]. Likewise it may be one way in which molybdenum is held in soils.

This work was done while one of us (A. A. M.) was holding a fellowship of the International Federation of University Women and working in the Department of Geology, University of Melbourne.

A Randomly Interstratified Kaolin–Montmorillonite in Acid Clay Deposits in Japan

It has been accepted that, in general, the principal clay mineral in so-called bentonite and acid clay from Japan is montmorillonite. This fact is generally true, but closer examination has shown that these clays are, in general, very complex with regard to their mineral components. Recently, we have found certain clays closely associated with acid clay deposits and showing unusual properties; moreover, such clays are not so rare as we have hitherto anticipated. The purpose of this communication is to discuss the general mineralogical properties of such clays as illustrated by two representative reference specimens (Awazu and Nata clays from Ishikawa Prefecture) selected as samples which are as free from impurities as possible.

The X-ray powder reflexions of these clays consist of several broad reflexions near those of montmorillonite or hydrated halloysite (Fig. 1, 1, Awazu clay; 2, Nata clay), and a quartz reflexion (Q) is found associated with them. There is almost total absence of basal reflexions in the range 0°–20° (2θ) in spite of clear occurrences of principal prism reflex-

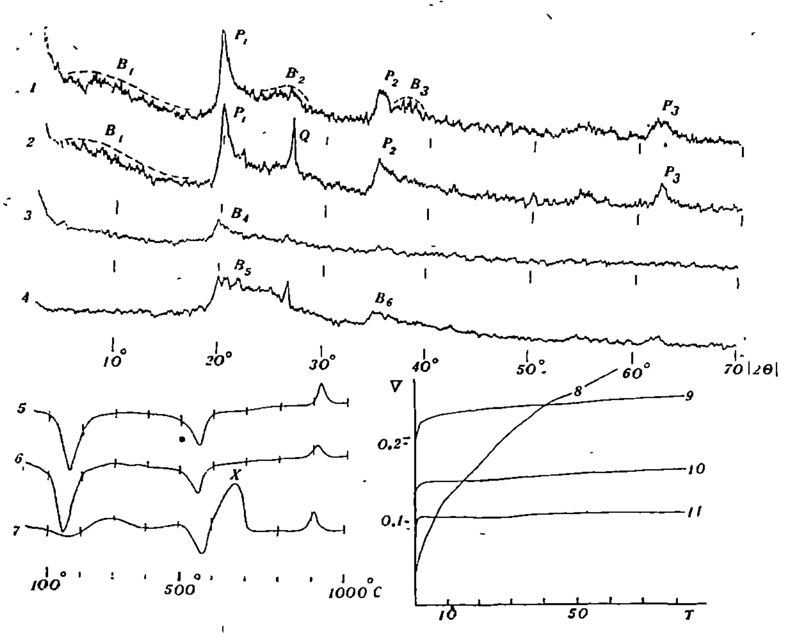

Fig. 1. Some properties of white clays associated with acid clay deposits in Japan. (1–4): X-ray diffractometer patterns. (5–7): differential thermal analysis curves. (8–11): the volume of absorbed water (V) in relation to time (T)

ions as P_1 (02,11), P_2 (13,20) and P_3 (06,33). The (06,33) reflexion occurs as a doublet (1·49 A. and 1·50 A.); the former spacing approximates to that of the kaolin minerals (1·486–1·497 A.) and the latter to montmorillonite (1·501–1·508 A.); these reference data have been obtained from Japanese specimens by us. On close examination, although basal reflexions are almost absent, it will be noticed that very broad bands (B_1) occur, spreading over the angle range of 5°–12° (2θ) (about 7–15 A.), including broad peaks having spacings of intermediate value between the two values above. Further, two broad bands are frequently noticed at about 3·5 A. (B_2) and 2·5 A. (B_3), which approximate to the (002) and (003) reflexions of a 7-A. kaolin mineral respectively. The effect of heat treatment at 600° C. and then air-quenching caused almost all powder reflexions to be weakened; only the (02,11) reflexion can be seen as a very broad band (Fig. 1, 3, B_4, Awazu clay). Treatment with ethylene glycol caused almost all reflexions to be weakened; even the (02,11) and (13,20) reflexions become very broad like a reflexion from a one-dimensional crystal (Fig. 1, 4, B_5, and B_6, Nata clay).

Differential thermal analysis curves (mean heating rate: 10 deg. per min.) are of the type of those of kaolin minerals (Fig. 1, 5, Awazu clay; 6, Nata clay). The thermal curves for the specimens treated by piperidine show the additional exothermic peak (X), indicating the presence of montmorillonite in the clays (Fig. 1, 7, Awazu clay). The chemical composition indicates an intermediate type between montmorillonite and a kaolin mineral; the data for Awazu clay are: SiO_2, 41·94; Al_2O_3, 30·12; Fe_2O_3, 2·42; FeO, 0·21; MgO, 1·52; CaO, 0·32; ignition loss, 11·10; H_2O (−) 12·88; TiO_2, 0·40 per cent; MnO, trace; total, 100·91 per cent. Electron micrographs indicate mainly plate-like crystals with somewhat irregular outlines, which mostly have elongated shapes. Crystals with pipe-like shapes are sporadically patchy. The change of the volume of absorbed water (V in c.c.) in relation to time (T in min.) (Fig. 1, 10, Awazu clay) is nearer to that of kaolinite (Fig. 1, 11) rather than those of montmorillonite (Fig. 1, 8, a specimen from Aterazawa, Yamagata; 9, a specimen from Ochiaizawa, Hanaoka).

These properties can be explained from our knowledge of clay mineralogy. Crystallites of these clays probably consist both of montmorillonite layers and kaolin mineral layers, and the proportion of these layers varies from portion to portion even in each crystallite. One hypothesis is that the core of each crystallite consists of montmorillonite (M) with kaolin mineral layers (K) becoming dominant, as one goes towards the edges, forming a randomly mixed layer mineral (Fig. 2). When such a crystallite is treated with ethylene glycol, swelling will occur selectively in the montmorillonite layers and it will give rise to small foldings in this crystallite, producing considerable disorder in the origina crystal structure. An alternative hypothesis is that the core is largely occupied by a kaolin mineral, and on going toward its margin, montmorillonite layers become dominant. Such a scheme of interstratification leading to swelling of water-layers was proposed for the first time by MacEwan[1] for soil clay minerals. On the basis of the ideal chemical formulæ of kaolinite and montmorillonite, the proportion of these two kinds of minerals can be estimated from the chemica composition as about 80 per cent kaolinite and 20 pe cent montmorillonite. It is very difficult to decide whether the kaolin mineral in question is kaolinit or hydrated halloysite as usually understood. X-ray diffraction data suggest that its crystallinity i lower; the 3·5 A. and 2·5 A. bands approximate to the (002) and (003) reflexions of a 7-A. kaolin minera respectively; but pipe-like shapes are only noticed sporadically.

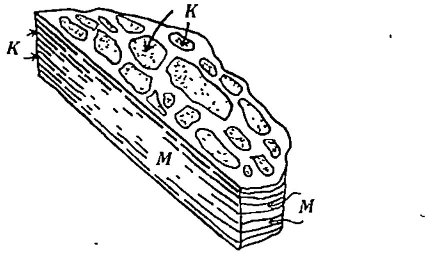

Fig. 2. Scheme for a mixed-layer mineral. K, Kaolin mineral layers; M, montmorillonite

We consider that such clays are alteration produc representing an intermediate stage in the alteration o montmorillonite toward a kaolin mineral or vice vers

Sensitivity to Ultra-violet Light of Infectious Tobacco Mosaic Virus Nucleic Acid

STRAINS of tobacco mosaic virus differ markedly in sensitivity to inactivation with ultra-violet light[1]. It is of interest to determine the basis for this difference in terms of the chemical structure of the virus strains. The discovery that the nucleic acid portion of the virus is by itself infectious[2,3] has enabled us to carry out experiments on the problem.

We have confirmed the observation that the nucleic acid fraction, prepared by the method of Fraenkel-Conrat and Williams[3], is infectious. We have also observed that an increased infectivity is obtained when the protein fragments are added to the nucleic acid preparation (reconstitution)[3,4]. Representative results are given in Table 1.

Table 1

	Conc. γ/ml.	Lesions on 30 half-leaves*
Untreated tobacco mosaic virus	0·10	2,400
Nucleic acid	60	1,355
Protein	50	0
Reconstituted tobacco mosaic virus:		1,566
Protein	25	
Nucleic acid	3	

* The assay consisted of a 5 × 5 Graeco-Latin square replicated three times.

Ultra-violet radiation survival curves were determined for the nucleic acid preparations from strains *U*1 and *U*2 [5]; strains which differ $5\frac{1}{2}$-fold in sensitivity to inactivation with ultra-violet light. Survival curves were also determined for preparations of reconstituted *U*1 strain. The preparations were irradiated at a concentration of 5×10^{-2} mgm./ml. in $M/15$, *p*H 6·9 phosphate buffer with a Westinghouse germicidal lamp, 782*L*-30, the output of which is primarily at 2537 A. Other techniques used for these experiments have been described[1]. The results are presented in Fig. 1. The nucleic acids from both strains *U*1 and *U*2 as well as the reconstituted *U*1 strain have the sensitivity of the *U*2 strain. It is of significance that the nucleic acids from the two strains do not differ in ultra-violet sensitivity; the difference in sensitivity of the strains thus cannot be attributed to differences which may exist in composition or structure of their nucleic acid fractions. Two preparations of reconstituted *U*1 strain had precisely the sensitivity of the nucleic acid, as indicated in Fig. 1. However, another preparation was intermediate in sensitivity between the nucleic acid and the untreated *U*1 strain. Fraenkel-Conrat and Williams[3] have indicated that the properties of reconstituted virus preparations may differ, depending upon the precise conditions of the experiment. Our data agree with theirs in indicating that preparations of reconstituted virus differ to varying degrees from the untreated virus. The fact that some of the reconstituted virus preparations have the same ultra-violet sensitivity as nucleic acid strongly suggests that the difference in ultra-violet sensitivity of the *U*1 and *U*2 strains cannot be attributed to a differential ultra-violet screening by their protein moieties.

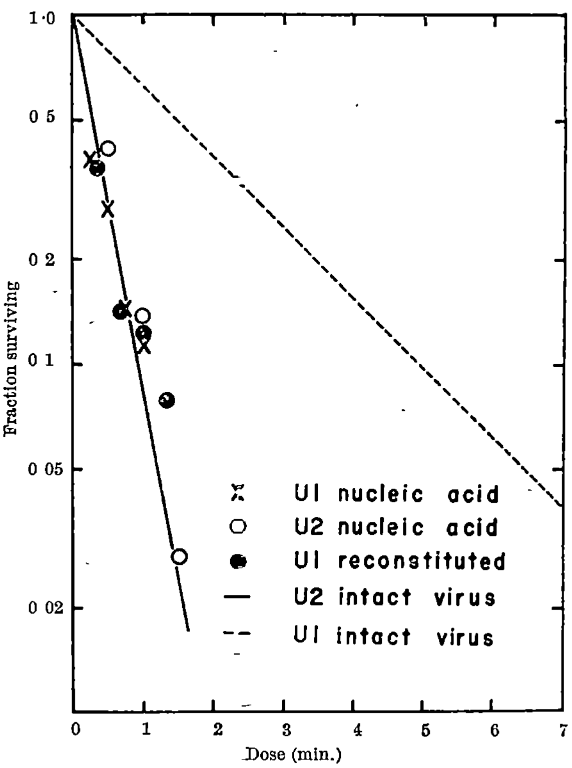

Fig. 1. The ultra-violet sensitivity of tobacco mosaic virus strains *U*1 and *U*2, the infectious nucleic acids derived therefrom, and one of the preparations of reconstituted *U*1 strain

The results presented here are most easily interpreted to signify that the difference in sensitivity of the two strains to inactivation with ultra-violet irradiation resides in the nature of the bonding between the nucleic acid and the protein moieties of the virus. The type of bonding existent in the *U*1 strain protects the virus from the full effect of the ultra-violet light, whereas the *U*2 strain is not so protected.

Since little is known of the chemical alterations induced by ultra-violet light which lead to the inactivation of biological materials, it is difficult to speculate upon the possible bonding mechanisms which would lead to the type of protection observed in the *U*1 strain. Two possibilities are: (1) that energy absorbed by the nucleic acid can be transferred into the protein, where it may have little effect upon biological activity; (2) that the protein holds the nucleic acid in such a configuration that damage to the nucleic acid is easily repaired. We have made two observations which suggest that the bonding between nucleic acid and protein is different for strain *U*1 compared to strain *U*2. One of these observations is that the nucleic acid of the *U*2 strain is released more easily than that of the *U*1 strain by the heat-detergent method of Fraenkel-Conrat and Williams[3]; the other, that the *U*2 strain is considerably more sensitive to heat denaturation than is the *U*1 strain.

There are other biological materials which, although similar, differ in sensitivity of response to ultra-violet light. For example, a two-fold difference in sensitivity to inactivation of a bacterial virus is controlled by a single gene locus[6]. Another case is that of the inosito locus in *Neurospora* in which alleles have different ultra-violet induced reverse mutation-rates[7]. It is possible that in these cases, as in the one presented in this communication, the nature of the bonding between the genetic and non-genetic material affects the response of the genetic material to ultra-violet light.

We are indebted to Miss Carol Hoelle and Mr. Charles Ford for technical assistance. This work was

Enzymic Oxidation of Glyceric Acid

THE reduction of hydroxypyruvate to glycerate is brought about by crystalline L-lactic dehydrogenase of muscle[1] with the production of L-glyceric acid[2]. A substrate-specific D-glycerate dehydrogenase, which may or may not be accompanied by lactic dehydrogenase, occurs in extracts of higher plants[2]. Hydroxypyruvic acid phosphate is not able to replace pyruvic acid as a substrate for lactic dehydrogenase[3]. These enzymes require diphosphopyridine nucleotide, and their equilibrium, being far towards the reduced metabolite, is unfavourable for the study of the oxidative production of hydroxypyruvate. The importance of this substance as a substrate for transketolase[4] and transaminase[5] led us to study the action on glyceric acid of preparations containing lactic dehydrogenase from yeast, which is not so inhibited by pyruvate and requires no coenzyme[6–8].

An aqueous maceration extract of dried Delft baker's yeast was fractionated by precipitation with ammonium sulphate (final concentration 0·65 saturated), dialysis against versene (10^{-1} *M* disodium ethylenediamine tetraacetate) and removal of interfering impurities by precipitation at *p*H 5 and adsorption on small quantities of calcium phosphate gel. Lithium hydroxypyruvate, $CH_2OH.CO.COOLi + 1\ H_2O$, was crystallized analytically pure from water, the molecule of water being very firmly bound and possibly constitutive (crystalline salts of this acid have not previously been reported). Hydroxypyruvate (and glycolaldehyde) were assayed, in the presence of glycerate, by a new colour reaction with naphthoresorcinol in 23 *N* sulphuric acid at 100° for 20 min., the absorption of the resulting green solution being read at 660 mμ. The enzymic reduction-rates with methylene blue as hydrogen acceptor showed widely different *p*H optima for lactate (*p*H 5·5) and glycerate (*p*H 6·7). D-Glyceric acid was not attacked, and with DL-glycerate the extent of oxygen uptake and of hydroxypyruvate formation indicated the oxidation of one isomer (L-glycerate) only. The ratio of oxidation-rates at *p*H 6·7 for glycerate/lactate was $\frac{1}{2}$, and the Michaelis constants at 37° were approximately $3\cdot5 \times 10^{-4}$ *M* (calculated) for L-lactate and $2\cdot5 \times 10^{-3}$ *M* for L-glycerate. DL-3-Phosphoglyceric acid was oxidized at about half the rate of DL-glycerate under these conditions, but some phosphate was split off; D-3-phosphoglycerate was not oxidized. Cytochrome *c*, like methylene blue, is reduced by glycerate in the presence of the enzyme preparation.

It is not yet clear if the same enzyme is responsible for the oxidation of lactate and glycerate in these experiments. The widely differing *p*H optima and the statement of Boeri *et al.*[7] that their highly purified yeast lactic dehydrogenase (cytochrome b_2) is unable to oxidize "any other α-hydroxy acid" would indicate different enzymes; on the other hand, no summation of reaction-rate occurs when lactate and glycerate are both present with our preparations. Further purification of the enzyme, now being undertaken, should decide this point.

An Apparent Anomaly in the Distribution of Radioiodinated Serum Albumin when added to Red Cell Suspensions

WHEN 15 ml. of suitably diluted (1 in 500) serum albumin tagged with iodine-131 ('*RISA*', Abbott) is added to an equal volume of washed human red cells with a volume concentration ρ of about 0·4, and when the red cells are thrown down by centrifuging at 7×10^2 *g* for 15 min., the radioactivity of the supernatant fluid is invariably 10–15 per cent greater than that found in a blank system containing 15 ml. of '*RISA*' plus 15 $(1 - \rho)$ ml. of saline, even after a correction is made for the volume of the blank system being smaller than the volume of the system with which it is compared. If the red cells are first rendered spherical by the addition of 1·5 ml. of a distearyl lecithin sol (5 mgm./5 ml.), the supernatant fluid obtained by centrifuging is 20–25 per cent more radioactive than the supernatant fluid from an appropriately prepared blank.

This apparently anomalous result is explained by the examination, with phase optics, of the respective supernatant fluids. While the red cells are thrown down by the centrifuging, the supernatant fluids from the systems to which '*RISA*' has been added contain minute fragments and myelin forms which are not thrown down even at a centrifugal force of 2×10^4 *g*. These fragments and myelin forms apparently take up '*RISA*'. They are not found when only distearyl lecithin is added to the red cells; they appear, usually as tiny spherical fragments, when '*RISA*' is added to the red cells, and usually as much more numerous worm-like myelin forms when '*RISA*' is added to red cells rendered spherical with lecithin. Their association with '*RISA*' accounts for the relatively high radioactivity of the supernatant fluids containing them, and suggests that the effect of serum albumin in reversing the disk–sphere transformation produced by lecithin is related to the loss of myelin forms from the red cell surfaces.

By using a device which consists of a scintillation probe mounted against a 1-mm. slit in a mass of lead, and by moving the centrifuge tube (25 mm. in diameter) containing the supernatant fluid upwards and downwards, some indication has been found that there are more radioactive myelin forms in the upper than in the lower layers of the supernatant fluids.

The tiny fragments and myelin forms in the supernatant fluids can be demonstrated excellently with the interference microscope (AO-Baker). The refractive index of the myelin forms is about 1·48, which is about the same as that of lipids, and their water content must be small. The measurements, however, are difficult to make because of the smallness of the objects and because they are in active Brownian movement, so these results are given as approximations only.

This investigation was made under a grant, *H* 1598, from the U.S. Public Health Service.

Effect of Thyroxine on the Swelling of Mitochondria isolated from Various Tissues of the Rat

Several recent investigations[1-4] have suggested that an important function of thyroxine may be an 'uncoupling' of oxidative phosphorylation. However, studies with a multi-enzyme system (isolated from digitonin extracts of mitochondria[5]) capable of performing oxidative phosphorylation have indicated[6] that thyroxine and its analogues have no direct effect on this process. Concurrently[7], it has been observed that these compounds alter the morphology of rat liver mitochondria *in vitro*. In concentrations as low as 10^{-6} *M*, both thyroxine and triiodothyronine produce a prompt and marked swelling of the mitochondria. In contrast, 2,4-dinitrophenol, in concentrations which completely 'uncouple' oxidative phosphorylation, provides protection against swelling. It has therefore been postulated[6] that the uncoupling of oxidative phosphorylation produced by thyroxine in intact mitochondria is secondary to an alteration in the morphology of the mitochondria and not the result of a direct interaction of the hormone with the enzymes of oxidative phosphorylation.

Not all tissues respond in the same degree to the *in vivo* administration of thyroxine. Gordon and Heming[8] found that the oxygen consumption of slices of liver, kidney, diaphragm and heart from thyrotoxic rats was significantly greater than normal, while that of slices of spleen, brain and testis was not increased. Gross and Leblond[9] investigated the distribution of injected iodine-131 thyroxine in the rat and found that high concentrations occurred in plasma, liver and kidney and considerably smaller or negligible amounts in all other tissues tested. Likewise, we have found differences among the various tissues in the degree of mitochondrial swelling produced *in vitro* by thyroxine and its analogues.

Table 1 illustrates the markedly different susceptibilities of mitochondria from several organs. Mitochondria were isolated from the liver, kidney, heart, spleen and testis of adult male Wistar rats and the swelling assay conducted spectrophotometrically in a medium containing 0 3 *M* sucrose and 0·02 *M tris*-(hydroxymethyl)aminomethane at *p*H 7·4, as previously described[7]. Diaphragm mitochondria were isolated in a similar fashion following homogenization in a Waring blendor. Brain mitochondria were isolated by method I of Brody and Bain[10]. Each value in Table 1 represents the percentage decrease in optical density of a suspension containing the compound tested (3×10^{-5} *M*) less that observed in a control sample without the added compound. These values are taken as a measure of the swelling produced by the compound. The relative effects of thyroxine and triiodothyronine varied with different samples of these substances; one lot of thyroxine was more effective than triiodothyronine and one less so. Table 1 demonstrates that the swelling produced is striking with mitochondria from liver and kidney, while that with mitochondria from diaphragm and heart is much less marked. In accordance with failure of slices of spleen, brain and testis to show any change in oxygen consumption in thyrotoxic rats[8], essentially no swelling was produced by thyroxine or its analogues with the mitochondria from these tissues.

Table 1. Degree of Mitochondrial Swelling produced *in vitro* by Thyroxine and Various Analogues

	L-thyroxine	D-thyroxine	L-triiodothyronine	D-triiodothyronine	Tetraiodo thyroacetic acid	Triiodo thyroacetic acid
Liver	30	33	47	41	25	17
Kidney	12	10	18	14	20	12
Diaphragm	5	4	7	7	5	5
Heart	2	2	9	5	9	9
Spleen	0	0	0	0	0	0
Brain	4	1	1	0	4	2
Testis	1	2	2	2	4	3

Amœbicidal Action of Azaserine

In 1954, a group of workers reported on a new tumour-inhibitory substance[1]. This substance, called azaserine, also possessed antibacterial activity against numerous microbial species[2]. Chemically, this substance is O-diazoacetyl-L-serine[3]. It has been reported that azaserine is a profound inhibitor of formate incorporation into the nucleic acids[4]. Since the role of nucleic acid synthesis is particularly important in *Endamoeba histolytica*[5,6], the effect of azaserine on the amœbæ was studied.

The activity of azaserine was assayed in bacteria-free cultures of *E. histolytica* in a medium previously described[7]. Azaserine was amœbacidal in concentrations of 1/10,000 (100 µgm./ml.)–1/20,000 (50 µgm./ml.). Adenine (100 µgm./ml.), adenylic acid (100 µgm./ml.) and 2,6-diaminopurine (100 µgm./ml.) completely reversed the inhibitory effects of azaserine. Serine, methionine, 4-amino-5-imidazolecarboxamide and leucovorin (tested singly and in various combinations) effected only a partial reversal of the toxic action of azaserine. Guanine, guanosine and guanylic acid were completely inactive in reversing the action of azaserine.

It seems that azaserine functions as an antimetabolite in purine ring biosynthesis. Its mechanism of action against *E. histolytica* may be the prevention of 1-carbon incorporation as postulated[4,8] in the *de novo* synthesis of purines or the prevention of the closure of the acyclic purine ring precursor, thus blocking the synthesis of nucleic acids. Although 6-diazo-5-oxo-L-norleucine, another new tumour-inhibitory substance, was reported to inhibit the incorporation of formate into nucleic acids[8], no activity could be demonstrated against the amœbæ.

This work was supported (in part) by the Office of the Surgeon General, Department of the Army, Contract No. *DA*-49-007-*MD*-711. I am indebted to Dr. C. C. Stock for a gift of azaserine and 6-diazo-5-oxo-L-norleucine.

Riboflavin in Milk

SUCH studies as have been made on the riboflavin in milk point to the existence of species differences in respect of the forms in which this vitamin occurs in milk. Thus Kon and Mawson[1] reported that the concentration of riboflavin in human milk is very low, and found that the method of Emmerie[2], in which riboflavin is extracted by methanol was inapplicable to it. Davis *et al.*[3] found the methanol method unsuitable for sow's milk, and at the same time suggested that riboflavin might be present in sow's milk in a form different from that occurring in cow's milk. In view of the foregoing observations, the partition of riboflavin between free riboflavin, flavin mononucleotide and flavin adenine dinucleotide in the milk of several species has been studied.

Riboflavin was extracted from milk by the method of Bessey *et al.*[4]. From the neutralized extract the riboflavin was extracted with liquid phenol. Addition of ether threw out an aqueous phase containing all the riboflavin. Both by paper chromatography and by paper electrophoresis, free riboflavin, flavin mononucleotide and flavin adenine dinucleotide were separated. For the chromatographic separation a butanol/acetic acid/water system was used (Crammer[5]). For the paper electrophoresis a borate buffer (0·05 *M* borax, *p*H 9·2) was used, and a potential of 300 volts was applied for 5 hr. giving a current of 1·5 m.amp. per cm. width. Distinctly separated spots were made visible by ultra-violet illumination, and known samples of free riboflavin, flavin mononucleotide and flavin adenine dinucleotide were used for their identification. R_F values of the flavins for the solvent system used in the chromatography were 0·04 for flavin adenine dinucleotide, 0·13 for flavin mononucleotide and 0·35 for free riboflavin.

With the milk of cows, goats, ewes and rabbits two spots were observed, the larger one corresponding to free riboflavin and the smaller one to flavin adenine dinucleotide. On the other hand, with human, mare's and sow's milks usually only one spot was obtained, which corresponded to flavin adenine dinucleotide. Occasionally, however, with these last three types of milk, faint spots corresponding to flavin mononucleotide and free riboflavin were observed, but they probably resulted from slight hydrolysis of the flavin adenine dinucleotide. The authenticity of the flavin adenine dinucleotide was always established by enzymatic assay in the D-amino-acid oxidase system.

The ultrafiltrates from cow's and goat's milk were yellow, and under ultra-violet light they showed the characteristic greenish fluorescence of free riboflavin, whereas the ultrafiltrates of human and mare's milk were colourless. None of the ultrafiltrates contained flavin adenine dinucleotide, which suggests either that this molecule was too large to pass through the filter membrane or that it was present in the milks in a bound form.

Since in human, mare's and sow's milks the riboflavin is present as flavin adenine dinucleotide it might be thought that these milks, compared with cow's, goat's, ewe's and rabbit's milks, would contain greater amounts of enzymes, such as xanthine oxidase, that have flavin adenine dinucleotide as their prosthetic group. However, preliminary experiments have shown that xanthine oxidase is absent from human, mare's and sow's milks but is present in the milks of the other four species. This work is still in progress.

Our thanks are due to Dr. F. E. Hytten of the Midwifery Department, the University of Aberdeen, for sending us frozen samples of human milk, and the Veterinary Investigation Officers of the West of Scotland Agricultural College, for obtaining samples of sow's and ewe's milk.

Nuclear Behaviour in Migrating Cells of the Rat's Corneal Epithelium

WHILE conducting a series of experiments on the healing of needle pricks applied to the corneal epithelium of albino rats, perforating the epithelium only, it was seen that migration and proliferation of cells occur simultaneously, and before the commencement of mitosis. Multiple injuries were made. The eyes were then left to heal in the animal for varying periods after injury and, after removal, fixation and staining with hæmatoxylin, cross-sections were made and examined in series.

As is known, in these minute wounds migration of cells of the wound wall and around the wound commences roughly one and a half hours after application[1]. My investigations revealed an occasional split nucleus in a migrating cell one and a half hours after injury.

Two hours after application, and before any appreciable mitotic activity of the cells could be detected, there was considerable increase in the number of cells of the wound wall. This increase was manifested by an annular prominence of the epithelium of the wound wall, around the wound hole, made up of cells with clearly discernible membranes, of varying size, for the greater part smaller than average, although cells of average and more than average size were seen, too. Exceptionally, cells of a size much greater than that of ordinary epithelial cells were encountered.

Among the cells of average or more than average size, some with split nuclei or nuclei with furrows were often found. The occasional very large cells were always either bi- or tri-nucleate, or the nuclei displayed one or more furrows. Split nuclei were not limited to cells of the basal layer. Although infrequently, abnormal mitoses were sometimes seen. These could not be detected one and a half hours after injury.

Three hours after injury, a fair number of abnormal mitoses were observed in the annular prominence. Occasionally, these occurred in layers other than the basal. Many approached the appearance of normal figures more than did those two hours after injury. Cells with split nuclei persisted.

At times a normal mitotic figure was found in the normal epithelium between the wounds.

Four hours after application of the injury many normal mitoses were seen in the epithelium between the wounds. In the annular prominence cells with split nuclei and abnormal mitoses persisted.

That there is strong inhibition of mitosis following such injuries of the corneal epithelium in rats was found by Friedenwald and Buschke[1]. They state that *in vivo* a return to normal count is found around the fourth hour and some overshooting occurs between four and six hours after injury.

From the above it was concluded that, as in this instance there is cell proliferation without any normal mitotic figures present, cell multiplication has occurred by a process other than mitosis. Consequently, injury as such causes a change in the mode of cell division in the immediate vicinity of a wound.

Further, from a detailed study of the mechanism of wounding[2] which showed that, at least in a certain area, the only injury to the migrating cells is through compression, it was concluded that, of itself, compression of the epithelium produces a change in the mode of cell division.

This work received financial support from the Council for Scientific and Industrial Research, South Africa.

Influence of Atropine and Morphine on the Liberation of Acetylcholine from the Guinea Pig's Intestine

IT has been shown by Chujyo[1] that distension of the lumen of the guinea pig's intestine results in an increased output of acetylcholine. Distension of the lumen also leads to a contraction of the longitudinal muscle, which is probably brought about by the acetylcholine released. Atropine and morphine abolish this contraction; but the mechanism of the action of these two drugs appears to be different. The following experiments show that whereas atropine apparently acts by preventing the action of the released acetylcholine on the longitudinal muscle, morphine inhibits the release of acetylcholine.

Distended strips of the guinea pig's small intestine were incubated in Tyrode solution aerated with 95 per cent oxygen + 5 per cent carbon dioxide at 38° C. in the presence of 10 μgm./ml. eserine. Four samples were obtained from the intestine of one animal; two were incubated in the presence of atropine or morphine, the other two served as controls. After 1 hr. incubation the Tyrode solution was removed, cooled, made isotonic to frog saline and assayed for acetylcholine on the eserinized frog rectus muscle. 1 gm. of intestinal tissue released between 2 and 6 μgm. acetylcholine per hr. The same release, or an insignificant increase in the release, was obtained when the experiment was carried out in the presence of 5 μgm./ml. atropine in the bath fluid. On the other hand, the presence of 10 μgm./ml. morphine in the Tyrode solution reduced the output of acetylcholine by 40–60 per cent although morphine is 3–5 times less effective in paralysing the guinea pig's ileum than atropine[2]. These results are given in Table 1; each figure represents the mean of two samples.

The present observation agrees with the corresponding one of Paton[3], who found that the output of acetylcholine from the intestine on co-axial electrical stimulation of the guinea pig's ileum was depressed by morphine.

The effect of morphine in preventing the release of acetylcholine brought about by distension or stimulation of the gut is best explained on the assumption that the acetylcholine is released from nerve fibres or nerve endings which are inhibited by

Table 1

morphine. The nature of these nervous structures, however, is uncertain. Ganglion cells can be excluded according to the results of Feldberg and Lin[4] and also because morphine does not inhibit ganglion cells in the intestine[2]. On the other hand, morphine was found to abolish contractions of the guinea pig's duodenum on stimulation of the vagi, probably by an action on postganglionic structures[5].

Incorporation of Methionine (Sulphur-35) into the Central Nervous System

TWENTY-FOUR hours after administration, methionine (sulphur-35) in the central nervous system is largely found in protein molecules[1,2]. In other words, incorporation of methionine (sulphur-35) is a good indicator of proteosynthetic activity of different parts and structures of the central nervous system.

A number of authors have studied the incorporation of methionine (sulphur-35) into the central nervous system[3-7]. In agreement with their work, it has been demonstrated that a relatively larger amount of methionine (sulphur-35) is incorporated into the grey matter of brain and spinal cord than into the white matter.

Experiments were carried out on eight male police dogs aged two years and adequately fed. Methionine (sulphur-35) was administered intraperitoneally (200 microcurie – 1 millicurie). Twenty-four hours later the animals were killed. The coated method was used for histoautoradiography with an emulsion developed in our laboratory[8].

Activity of sulphur-35 determined in mineralized tissues[1] decreases in the following order: cerebellum, brain cortex, pons, spinal cord, peripheral nerve.

Autoradiography of coronal sections of the brain showed that methionine (sulphur-35) accumulates to a larger extent in the grey matter (Fig. 1). No obvious differences between the activity of the grey matter of the cerebral cortex and of basal ganglia could be demonstrated. The isotope does not accumulate extensively in the areas surrounding the ventricles.

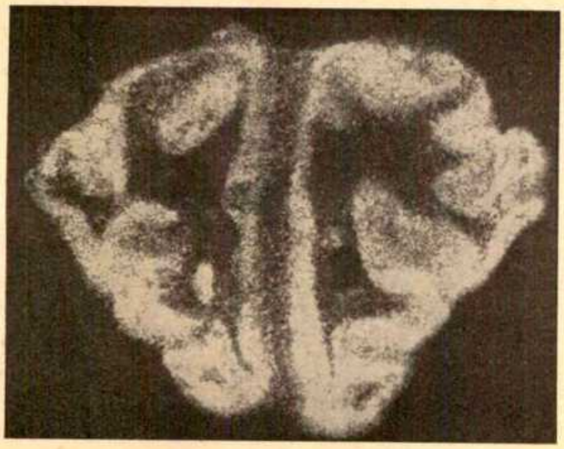

Fig. 1. Coronal section through the brain of the dog, showing greater incorporation of methionine sulphur-35 in the grey matter of the cortex

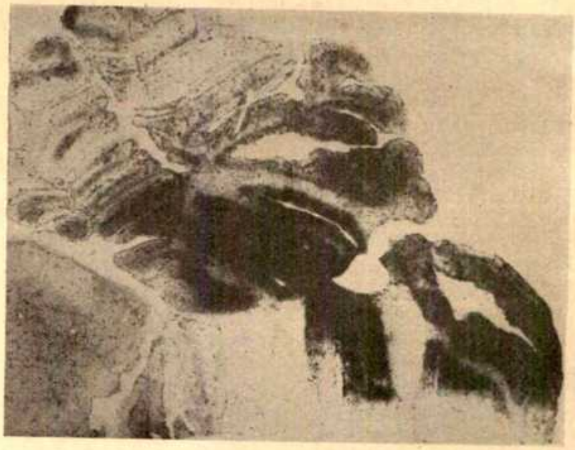

Fig. 2. Incorporation of methionine sulphur-35 into the cerebellum. Higher concentrations are present in phylogenetically older regions of the cerebellum. Unstained. (× 15)

The following areas were historadiographed: gyrus sylvius ant. and post., g. sigmoideus post., g. enterolateralis (occipital pole), basal ganglia, palleo- and neo-cerebellum, pons, spinal cord. In certain cellular structures of the cerebral cortex accumulation of methionine sulphur-35 could not be demonstrated. The same holds good for the grey matter of the pons and basal ganglia. The border-line between grey and white matter is relatively sharp, activity in the white matter being up to twice as low as in the grey matter. In the cerebellum activity

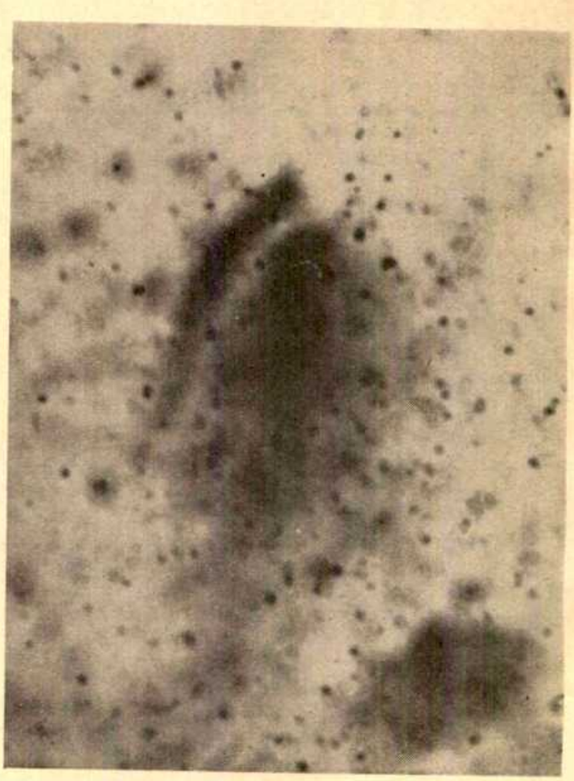

Fig. 3. Concentration of methionine sulphur-35 in motor cell from anterior spinal horn. Coated radioautograph. Hæmatoxylin–eosin. (× 975)

is highest in the medial parts (phylogenetically old cerebellar areas; Fig. 2). Under higher magnification it is possible to demonstrate greater accumulation of methionine sulphur-35 in the granular layer of the cerebellar cortex.

Methionine sulphur-35 is not distributed equally throughout the grey matter of the spinal cord. The largest amount is present in motor cells of the anterior horn (Fig. 3). Even in the anterior horns it is possible to differentiate cells with activity higher than the rest.

Very little methionine sulphur-35 is present in the cerebrospinal membranes. No accumulation of methionine sulphur-35 could be demonstrated in the central nervous system surrounding blood vessels or in the vascular walls themselves.

Possible Interaction of Anti-diuretic and Sodium-retaining Hormones in the Kidney

While investigating the renal excretion of water and sodium by rats in response to intravenous infusion of isotonic saline[1,2], it became desirable to consider some aspects of the renal tubular re-absorption of these substances[3]. We have attempted to do this by considering a model of the tubules based upon properties of a membrane the characteristics of which have already been studied. Some properties of frog skin have been described by Ussing and Zerahn[4], and it seems that this membrane can act as a 'sodium pump', actively transferring sodium ions; the activity of the 'sodium pump' appearing as an e.m.f. of about 100 mV. across the membrane. The rate of water transfer may be regarded as dependent upon hydrostatic and osmotic pressure differences across the membrane and upon its permeability to water.

For a membrane having these properties the rate of sodium transfer may be shown to be a function of the rate of transfer of water and vice versa. In this case a change in the flux of water across the membrane may lead to a similarly directed change of the sodium flux. Were the e.m.f. developed by the 'sodium pump' controlled by a sodium-retaining hormone and the permeability of the membrane to water by an antidiuretic hormone[5], then there would appear to be an interaction between these two hormones which is, however, a function of the membrane upon which they act.

It is suggested that the activity of the renal tubules in re-absorbing sodium and water from the lumina may show properties not entirely dissimilar from the characteristics of frog skin mentioned above. On this supposition the renal responses to certain physiological stimuli have been deduced and found to agree with observations. In particular, the excretion of a urine initially hypotonic in response to an isotonic saline infusion is explained, as also is the inability of physiological doses of antidiuretic hormone to inhibit diuresis caused by infusing isotonic or hypertonic saline.

Effect of Fast Neutrons on Different Stages of Spermiogenesis in *Drosophila melanogaster*

From X-ray studies, it is known that the rates of chromosome aberrations vary with the age of the males[1] and the time from irradiation to insemination[2]. Lüning[3] showed that these variations were due to differences in the rates of chromosome breaks in different stages of spermiogenesis and that in spermatids there was a higher rate than in mature spermatozoa. After Baker and Von Halle's[4] observation that there was a difference in the rate of dominant lethals in sperm between the first and second day, this was further studied by Lüning[5] on other types of aberrations. He proposed that this difference was due to a difference in the rate of breaks in 'mature' (the first-day) and 'near mature' (the second-day) sperm. This conclusion ought, however, to be revised as some yet unpublished experiments have shown.

From experiments by Baker and Von Halle[6] with fast neutrons it is known that the rates of dominant lethals were the same in sperm from the first and the second day. This result is difficult to explain on the hypothesis of a difference in sensitivity between sperm of the first two days.

Hence it seemed to us worth while to attack the problem of different sensitivity by means of irradiation with fast neutrons also on other types of aberrations. In this study we used two types of mutations, namely, sex-linked recessive lethals, and II–III translocations. The purpose of this experiment was also to obtain information concerning the effectiveness of the fast neutrons compared with X-rays on the two types of mutations. In order to be sure that the dose and stages in spermiogenesis were the same for both types of mutations, certain precautions have to be taken. In our case we used a 'dual-purpose' stock from which we could take the daughters for tests of recessive lethals and their brothers for translocation tests.

Table 1

Day of mating after irradiation	Recessive lethals		
	X-chr. tested	Lethals	
		Abs n : r	Per cent
1	918	10	1·09
2	953	9	0·94
5–6	1,137	24	2·11
Day of mating after irradiation	II–III translocations		
	II–III chr. tested	Translocations	
		Abs n : r	Per cent
1	1,042	32	3·07
2	1,021	35	3·43
5–6	794	61	7·68

The males were taken from *sp* ; *th* stock, the females from an sc^{S1} *B InS* w^a sc^8 ; *cn bw* ; e^{11} stock. The *X*-chromosome in this is the so-called Muller-5 = *M*5. The males were irradiated in the Swedish uranium reactor when 1–24 hr. old. They were afterwards mated to virgin females and then transferred to new virgin females at the following times after irradiation, 24, 48 and 96 hr. They were discarded 144 hr. after the treatment. Eggs were collected from females mated during the first, second and fifth–sixth day after treatment. The F_1 daughters were mated singly to *M*5 males in vials and the F_2 offspring was then examined for the occurrence of recessive lethals. The F_1 males were mated singly to *cn bw* ; e^{11} females and their offspring was analysed for II–III translocations. The results are presented in Table 1.

A comparison between the first and the second broods shows no differences for both types of aberrations, which is in agreement with Baker and Von Halle's results. The comparison between these first two days on one hand and the fifth–sixth day on the other shows for both types of mutation about twice as high a frequency in the latter as in the former.

These results confirm Baker and Von Halle's observations on dominant lethals, as the same rates of recessive lethals and translocations respectively are induced in the first as in the second brood. Hence one might conclude that the same rates of breaks are induced in the sperm of the two batches. In sperm supposed to have been irradiated in the spermatid stage a significantly higher rate of aberrations of both kinds was induced. This is in agreement with the results after X-ray irradiation and is consistent with the hypothesis of a differential sensitivity of various stages in spermiogenesis. It is, however, not possible to determine whether the degree of sensitivity is the same for X-rays and fast neutrons.

From the experiments presented above we may conclude that fast neutrons induce about the same rate of chromosome breaks in sperm to be inseminated during the first two days but a significantly higher rate in sperm to be ready during the fifth–sixth day mating period.

Production of Heteroploidy in the Three-Spined Stickleback, *Gasterosteus aculeatus* (L.)

Many data exist on natural and induced polyploidy in Amphibia[1,2] ; but knowledge on the subject still remains scanty in other groups of vertebrates. Spontaneous and experimentally produced polyploidy has been studied in mouse embryos[3-7]. Among fishes, production of triploidy by cold treatment has been reported up to cleavage stages[8]. The present work has been undertaken to induce triploidy by heat and cold treatment of the eggs of the three-spined stickleback and to keep alive the triploids thus produced.

The diploid number of chromosomes of *Gasterosteus aculeatus* as studied from squash preparations of testes, entire embryos and conjunctiva of the eyes of adult fishes is 42 ± 2. The small size of the chromosomes still leaves some doubt whether the observed variation in the counts is due to technical limitations or to an actual variation in the chromosome number of different individuals.

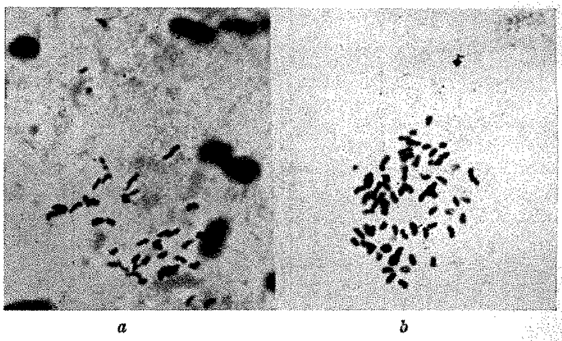

Fig. 1. Squash preparation of the conjunctiva of (*a*) diploid, and (*b*) triploid juvenile fish showing 42–44 and 63–66 chromosomes respectively. (× 1,000)

For the production of triploidy, the eggs, just after insemination, were subjected to heat or cold treatment which probably suppressed the formation of the second polar body and resulted in the fusion of two maternal and one paternal sets of chromosomes. The best temperature for heat treatment was between 32·5° and 34° C. provided the eggs were treated for 5 min. within 15 min. after insemination. However, heat shock always resulted in a high rate of mortality and the production of many abnormalities in the surviving embryos. Therefore cold treatment, which yielded better results, was preferred. It was soon noted that the fertilized eggs can bear a temperature of 0° C. up to 3 hr. ; those treated for 5, 6 and 15 hr. died at cleavage stages. In order to find the best time at which to begin the treatment, the eggs were exposed to the cold treatment for 3 hr., beginning at 3, 5, 10 and 15 min. after insemination. The results obtained are shown in Table 1.

Experiments for triploidy are successful only if the eggs are treated with cold within 5 min. after insemination, 3 min. being the best time. A cold treatment of 3 hr. still causes a very high mortality. The shortest treatment which produces triploidy without causing too high a mortality was found to be 1½ hr. (see Table 2), and hence all later experiments were confined to this treatment.

The construction of a simple apparatus which produced a continuous current of water made easy the

Further Observations on the Blood Factor Di^a

IN a previous communication[1] we remarked that the blood factor Di^a promised to be of great anthropological interest: it might prove to be a Mongoloid characteristic. Since then we have, on one hand, found it in a second northern Indian tribe—the Crees of northern Manitoba—three Di(a+) out of thirty-five, and on the other hand in none of thirty-five American Negroes, while Dr. Layrisse tells us that he has tested a number of Nigerians without finding any positive. It looked, indeed, as if Di^a were a Mongoloid 'marker', so it came as a surprise when we found no Di(a+) among 156 Eskimos.

Both the Cree Indians and the Eskimos were patients in tuberculosis sanatoria. Since the frequency of the factor in these Crees was essentially the same as in the neighbouring healthy Chippewa it would not seem that there could be any relationship between the facts that the Eskimos had tuberculosis and that they were all Di(a−). The use of sanatorium populations has the advantage that the patients come from many small populations scattered over a wide area and in this sense represent a random sample of the general population of that area. Laughlin[2] has pointed out the variations that occur in the blood-group gene frequencies in smaller and larger isolates among the Eskimo. We think the sanatorium method of sampling should give a true overall picture. The Eskimos tested were all from the eastern Canadian arctic, which includes Hudson Bay, Baffinland and Labrador. We hope to extend these studies to the western arctic.

Bacteriological Studies of 'Infected' and 'Uninfected' Chicks in Relation to Antibiotic Growth Stimulation

COATES *et al.*[1] described an infective growth-depressing condition in premises where chicks had been reared for some time. The condition was counteracted by penicillin in the diet, and was not present in clean premises where chicks had not previously been kept. Work on the relationship between *Clostridia* and antibiotic growth stimulation has been critically reviewed by Jukes[2].

In our investigation of the so-called infection, the gut flora of chicks from clean and infected premises was examined during the first few days of life; a gut flora similar to that of adult birds was found in chicks two days after they began to feed[3]. Spores of *Clostridium welchii* type *A* were found in the cæca of chicks from the infected premises one day after feeding, but not in those from the clean environment. Total counts made in series with spore counts showed that *Clostridia* are one of the most numerous components of the developing gut flora of the chick.

In further experiments the infected premises were thoroughly cleaned and redecorated, and the first batch of chicks placed therein was examined. *Cl. welchii* was not found in these birds, but was present in the cæca of chicks from the original clean premises. The chicks from the original clean quarters were infected, that is, their weights were depressed, in comparison with the weights of chicks from the redecorated premises. Subsequent batches of chicks placed in the redecorated premises showed growth depression compared with penicillin-fed controls, and also *Cl. welchii* in their cæca. Thus the presence of *Cl. welchii* in the cæca of chicks one day after feeding indicated 'infection'.

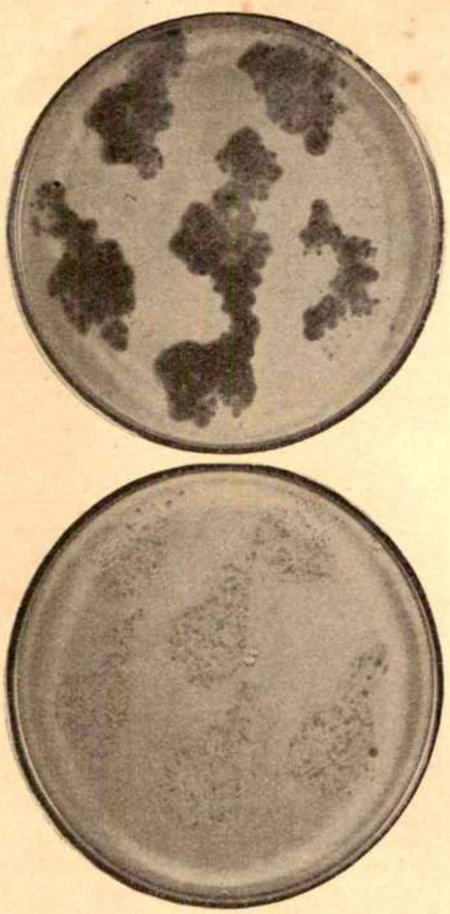

Fig. 1. Differences in lecithinase production on neomycin egg-yolk agar between *Cl. welchii* from 'infected' (top) and penicillin-fed (bottom) chicks

Further experiments were made with birds from infected premises with and without penicillin in the diet, *Cl. welchii* being enumerated by the method of Lowbury and Lilly[4]. In the first experiment of this series, *Cl. welchii* was not found in either group one day after feeding; however, it appeared on the second day in the control group, but not in the group fed penicillin. *Cl. welchii* was not found in the penicillin-fed group in three subsequent experiments on either the first or second day. In another experiment chicks from an alternative source were used, and *Cl. welchii* occurred in both penicillin-fed and control groups in equal numbers. However, Fig. 1 shows that, in contrast with the activity of *Cl. welchii* strains from the control group, lecithinase (α-toxin) production on neomycin egg-yolk agar was markedly less in strains from the penicillin group (lower plate); the dark areas show lecithinase activity. Strains of *Cl. welchii* from this group produced as much lecithinase when subcultured in the absence of penicillin as strains isolated from the control group.

The presence of *Cl. welchii* in the gut of chicks thus appears to be related to the growth-depressing condition. There are distinct differences in the presence and activity of *Cl. welchii* in the first few days of life between chicks from clean and infected premises, and between infected and penicillin-fed chicks. Moreover, the metabolism of at least one component (*Cl. welchii*) of the flora of infected chicks can be altered by penicillin in the diet, the effect for the host being equivalent to elimination of the organism. The experimental details of this work will be published elsewhere.

Linkage Group XIV of the House Mouse

PRELIMINARY linkage tests with the house mouse mutant 'crinkled'[1] showed a deficiency of recombinations between crinkled and flexed-tail[2] in repulsion inter-cross matings. Owing to a serious shortage of flexed-tail segregants, back-cross matings in coupling and repulsion were set up to estimate the percentage recombination between these loci. Because of the lack of vigour of crinkled flexed-tail homozygotes, these could only be used as male parents. Consequently, the recombination observed refers to that of doubly heterozygous females. Flexed-tail was classified within 24 hr. of birth by the transient anæmia visible at that age, and crinkled at 1–2 weeks of age by the appearance of the coat and tail. The number of offspring from the back-cross matings are given in Table 1.

Table 1

Phase	Normal	Flexed and crinkled	Flexed	Crinkled	Total
Coupling	49	32	17	23	121
Repulsion	54	29	65	95	243

There is a shortage of flexed-tail animals which may, in part, be due to pre-natal losses, but is certainly mainly due to losses after birth and before the classification for crinkled. There is no evidence to suggest that with classification of flexed-tail by the anæmia visible at birth, the deficiency may be due to normal overlapping (see also Grüneberg[3]). To allow for reduction in viability, the data for coupling and repulsion phases were combined by Fisher's method[4]. The estimated recombination percentage between crinkled and flexed-tail is 33·6 ± 2·6 per cent.

Linkage tests of crinkled were made with marker genes in all the known linkage groups except IV for which no suitable marker was available. The results are summarized in Table 2, which shows the estimated recombination percentages and thei standard errors obtained by the procedure of Carter and Falconer[5].

The values obtained show no significant deviation from independent assortment of crinkled with any other marker. In addition, published data[6] provid no evidence that the flexed-tail locus is linked to

A Rare Estuarine Copepod Crustacean, *Enhydrosoma garienis*, found in the Holocene of Kent

AMONG some small organisms including a single ostracod shell, washed from a sample of clay brought to me for identification by Dr. W. A. Macfadyen, was a small tapering object about ⅓ mm. long, terminating in a fine seta. The silty clay, penetrated by fine contemporary rootlets, had been collected from 6 in. below a Neolithic floor by Mr. J. P. T. Burchell at Lower Halstow, Kent. The object, when examined under the microscope, was seen to be a copepod complete with furcal rami and at least some of its appendages. As a zoologist, knowing how difficult it is to sort out these minute crustacea from a few drops of mud and water, I was surprised that anyone could have found so small a specimen in a pound of dried clay and mounted it with gum tragacanth intact on a black cardboard microscope slide.

The minute size of the specimen is indicated in Fig. 1 by comparing it with a fragment of the 'dust' from an electric shaver. Copepods are delicate organisms living in water, and contract and shrivel so badly on drying that no zoologist would think that a recent specimen mounted on card would be worth looking at. Dr. Macfadyen's skill in finding and preserving so small and delicate an object, presumably thousands of years old, however, goaded me into investigating the specimen further.

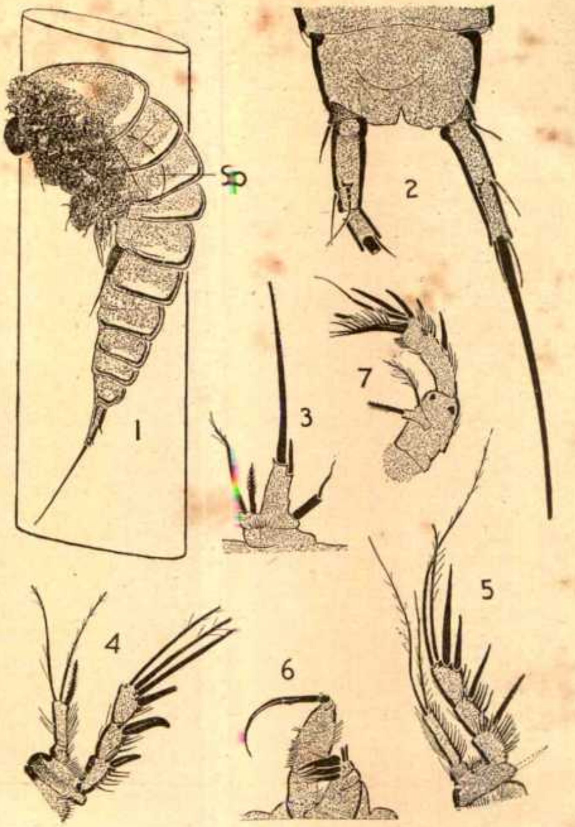

Fig. 1. *Enhydrosoma garienis* Gurney (male). 1, The intact specimen after relaxing and clearing. (*sp.*) spermatophore: outline drawn to the same scale of one day's growth of a human hair on a male chin (× *c.* 140); 2, dorsal view of the last segment of the abdomen and furcal rami; 3, the fifth leg; 4, the third leg; 5, the second leg; 6, second maxilla and maxillipede; 7, second antenna (Figs. 2–7 × *c.* 410)

After being soaked off the black card the object was boiled in a 2 per cent solution of tribasic sodium phosphate in order to soften and relax it. This treatment is recommended by Harley and Ross[1] for reclaiming dried arthropods and nematodes. The specimen was then cleared in lactic acid and some of the debris still adhering to it was removed with needles. The appearance of the specimen is shown in Fig. 1, which is drawn from a photograph taken at that time. The copepod was evidently a male as not only could a swollen first antenna be seen among the extraneous matter still covering most of the appendages but inside the animal could quite easily be seen the chitinous walls of a spermatophore (*sp.*). The fifth leg was still intact and the furcal rami with their setæ practically complete (Fig. 2).

Up to this time, I had thought that the specimen was probably a well-known British freshwater species which had somehow reached the clay. The rather unusual shape of the furcal rami, however, showed at once that it was not to be found in Gurney's monograph[2], nor in Sars's[3], which includes most likely marine species as well. Further progress could only be made by dissection. This was achieved using a Labgear–Harding microdissector[4].

The animal was dissected in lactic acid and the parts mounted in polyvinyl lactophenol, after staining with lignin pink. With the exception of the mandible and first maxilla all the appendages on both sides of the animal, that is, nine pairs, were successfully removed and mounted permanently on a slide, now preserved in the Palæontological Department of the British Museum (Natural History). A selection is shown in Figs. 3–7. Apart from some of their tips, nearly all the setæ are still intact. The outer seta on the basis of leg 2 (Fig. 5) is shown in dotted outline only, as it was absent from the leg drawn but present on its fellow from the opposite side. The corresponding setæ of the third leg (Fig. 4) was missing on both sides.

The species proves to be *Enhydrosoma garienis* Gurney[5] described from Breydon Water, Norfolk, the estuary of the Rivers Yare and Waveney, which Gurney describes as subject to great changes in salinity. It has not been recorded since its original discovery, so far as I am aware, and the specimen from the Holocene clay is only the second male ever to be found, as Gurney had only one male. The prehensile first antenna and the fifth leg (Fig. 3) are almost identical with Gurney's figures. The furcal ramus (Fig. 2) is very different from the furcal ramus drawn by Gurney, which was from a female, but agrees with his description of that of the male. The third leg of the male is also figured for the first time here (Fig. 4).

E. garienis is the only species of the genus which is not completely marine in habitat, so that for an understanding of the earlier conditions of the Neolithic site it is fortunate that Gurney found and described his few specimens of this, the only estuarine species.

I must express my thanks to Dr. Macfadyen for giving me the specimen to investigate.

Flowering Responses of Some Palestinian Legumes to Photoperiod and Temperature

A LATE autumn outdoor sowing was made of eighteen species of wild-growing leguminous annuals. As soon as the seedlings were big enough to handle, they were potted and grown under fixed photoperiods of 9, 12, 15 and 18 hr., and at natural day-length, in a heated greenhouse in which the temperature was thermostatically maintained above 14° C. A parallel outdoor control series, comprising the genera represented by more than one species, was exposed to lower average temperatures, with minima frequently amounting to only a few degrees above zero. Each treatment lot consisted of five replications. The natural day-length diminished during the experimental period from 11 hr. 15 min. to the annual minimum of 10 hr. 25 min., and then went up again to just under 12 hr. by the time all flowering was over on the greenhouse plants. Observations on the outdoor plants were continued until May 1, when the length of day was 13 hr. 25 min.

The photoperiodic treatments have been tabulated in the order of increasing time-interval from germination to flowering (Table 1). Individual treatment means have been omitted, and photoperiodic indications have been bracketed into statistically homogeneous groups, each group being furnished with the estimate of its mean. Non-homogeneous groups differ significantly at the 5 per cent level.

* Natural day-length.

The fact that, however tardily, flowering sets in eventually even under the 9-hr. photoperiod and the absence of a photoperiodic threshold defy any traditional photoperiodic classification. It seems that these legumes would be most appropriately classified, according to Chouard[1], as "plantes héméropériodiques préférantes", with *Medicago* possibly fitting in better with this author's "plantes eurypériodiques". It is noteworthy that in the case of *Melilotus sulcatus* and some species of *Trifolium*, the natural day-length, which did not quite attain 12 hr. in the greenhouse series, significantly advanced flowering as compared with the 12-hr. photoperiod. The gradual lengthening of the day apparently exerts a stimulating effect, as distinct from the effect of static photoperiodic values.

On the assumption that the difference in temperature-levels constitutes by far the most essential difference between the outdoor series and the greenhouse natural day-length control, the differences in the number of days from germination to the onset

Table 2. Effect of Temperature on Flowering at Natural Day-length

Species	No. of days from germination to flowering High temperature	Low temperature
Trigonella spinosa	91	160

L.s.d. for temperature effect at $P = 0{\cdot}05$, 36·06.

of flowering (Table 2) can be taken as an indication of the effect of temperature on flower induction.

It appears that in all the species tested, flowering is considerably hastened by high temperature. This response is somewhat at variance with that recorded for related pasture legumes[2] and actually indicates a behaviour diametrically opposed to that attributed to certain species of *Trifolium* and *Medicago*[3].

It is rather interesting that the species investigated, all of which flower in the early spring in a region of a relatively short day, respond readily to such long photoperiods as 15 or even 18 hr., which can be assumed to be entirely outside the scope of their evolutionary experience. It is obvious that, in the absence of a critical threshold, a purely quantitative response to day-length does not in itself constitute the flower-inducing mechanism. The time of flowering would appear to be determined by an interplay of photoperiod and temperature. The gradually increasing day-length coupled with rising temperature in the spring evidently induces flowering when a suitable combination of the two complementary factors is reached.

I thank Mr. S. Zacks for assistance in the carrying out of statistical computations. A fuller account of this investigation, including additional information on the growth and development of the experimental plants, will be published elsewhere.

Anthracnose Fungi of Olives

In published reports on anthracnose disease of olives, mention is made of only one responsible organism, the fungus described by Almeida[1] as *Gloeosporium olivarum*. I have observed that the causal organism of olive anthracnose in South Africa differs greatly from European and American isolates in spore morphology and cultural characteristics. The spores from Portuguese and South African isolates are much narrower than those isolated in Italy and the United States. The South African fungus develops a pink pigment in the mycelium on potato dextrose agar, as does the Japanese[2] fungus; but isolates from Portugal, Italy and the United States have a grey to olive-green mycelium. The spores from the Italian isolates agree very closely with those of *Colletotrichum gloeosporioides* Penz., and as Ciccarone[3] observed setæ in the fungus from olives it is very likely that the two are identical. Spores from a Californian[4] isolate showed close agreement with the spores of *Glomerella cingulata* (Stonem.) Spauld. and v. Schrenk; they are as broad as, but decidedly shorter than, those of *Colletotrichum gloeosporioides*. The Italian and American isolates differ from the Portuguese and South African forms also in the method by which the conidia are produced. The latter fungi are characterized by the formation of abundant microspores on the mycelium, which are much smaller than the spores formed in the acervuli; in the former, spores are only sparingly formed on the mycelium and they are of about the same size as the acervular spores.

Such wide variation in spore size and cultural features raises doubt whether all the anthracnose fungi of the olive should be regarded as *Gloeosporium olivarum* Alm. In my opinion they should not, for I found that the South African fungus was morphologically and culturally indistinguishable from the chromogenic strain of *Glomerella cingulata* that Dr. M. C. Goldworthy of Beltsville, United States, isolated from apples[5]. The South African fungus could even produce a rapid fruit rot when inoculated into apples. Another reason for considering the South African fungus as distinct from *Gloeosporium olivarum* Alm. is that the former can cause a blossom blight, which has never been reported as a feature of the olive disease in Portugal. The South African fungus is therefore considered identical with Goldworthy's chromogenic strain of *Glomerella cingulata*. However, in respect of spore size and method of spore formation this strain is much more closely related to *Gloeosporium olivarum* than to most other strains of *Glomerella cingulata*. It is felt that this should be expressed in the name.

It is known that *Glomerella cingulata* is extremely variable. Its strains can, however, be grouped in seven different types, two of which have not been known to produce perithecia[6]. Both conidial types (one is the pink chromogenic strain) possess the slender spores which are so typical of the non-perithecia-forming *Gloeosporium olivarum* Alm. Hence it is thought that the slender-spored conidial strains of *Glomerella cingulata* should not be included in this species; but rather that Edgerton[7] should be followed in distinguishing between non-perithecia-forming and perithecia-forming strains of *Glomerella cingulata* and identifying the first with the name *Gloeosporium fructigenum* Berk. The chromogenic strain of *Glomerella cingulata* could then be conveniently called *Gloeosporium fructigenum* Berk. f. *chromogenum* Gorter form. nov. = Goldworthy's chromogenic strain of *Glomerella cingulata* (Stoneman) Spauld. and v. Schrenk *loc. cit.*[5] which apparently not only causes an anthracnose of apples and olives but also of peaches[8]. To bring out the close relationship which exists between *Gloeosporium fructigenum* Berk. f. *chromogenum* and *Gloeosporium olivarum* Alm. from Portugal (cross-inoculations on apple are also possible), the latter should be renamed *Gloeosporium fructigenum* Berk. f. *olivarum* (Alm.) Gorter comb. nov. (= *Gloeosporium olivarum* Almeida *loc. cit.*[1]).

The presentation of this preliminary communication seems desirable as this is the first time that more than one anthracnose fungus has been identified on olives.

The implication is that caution should be exercised in ascribing anthracnose of olives to *G. olivarum* Alm.

Ætiology of European Foul Brood; a Disease of the Larval Honey-bee

THE cause of European foul brood was originally thought to be *Bacillus alvei*[1] or a mixture of *B. alvei* and *Streptococcus apis*[2]. The causative organism was later named and described by White[3] as *Bacillus pluton*, a lanceolate Gram-positive bacterium. This organism is the first of several which have been found to appear in diseased larvæ. However, White and others failed to culture *B. pluton in vitro* and it was afterwards considered to be a dissociant form of *Bacillus alvei*[4], of *Bacterium eurydice*[5], or of both[6]. Others[7,8] have maintained that *B. pluton* is a separate organism. It has been pointed out that *Streptococcus pluton* would be a more suitable designation than *Bacillus pluton* both on morphological grounds and in the absence of evidence that it forms spores. For these reasons and those given below the organism will be referred to as *Streptococcus pluton*.

Attempts have recently been made, by Prof. L. P. Garrod (St. Bartholomew's Hospital), to cultivate *S. pluton*, from diseased larvæ[9]. A Gram-positive encapsulated, pleomorphic, usually oval coccus which grew in anaerobic conditions on glucose–broth agar, was repeatedly isolated from diseased larvæ. Some evidence was obtained on one occasion that this bacterium grew in honey-bee larvæ and developed into an organism morphologically identical with *S. pluton*, but the disease failed to develop in this and in repeated experiments.

During further attempts to re-isolate the organism on special media, I have recently been able to isolate a bacterium which is probably the same as that previously isolated by Garrod; but its growth is relatively much stronger, and it is now morphologically stable. It appears to be *S. pluton*. The organism can readily be isolated in anaerobic conditions on a medium composed of: 1 per cent yeast extract ('Difco' yeast extract is very suitable); 1 per cent glucose; 0·1 molar potassium dihydrogen phosphate; 2 per cent agar. Adjust to *p*H 6·5 with concentrated potassium hydroxide. Sterilize by steaming or in the autoclave at 5-lb. pressure (108° C.).

The optimum temperature for growth is about 35° C. The optimum *p*H is about 6·5; no growth occurs at or below *p*H 5·5. The colonies are small (never more than about 1·5 mm. in diameter), round, entire and convex. They are transparent and microscopic after 24 hr., just visible and granular after 48 hr., and become very granular and pearly white by reflected light and almost opaque and slightly brown by transmitted light after three days. The organism grows as a lanceolate *Streptococcus* in chains of variable lengths. It has a thick cell wall, is highly refractile in watery suspension and is Gram-positive. Carbohydrate is essential; but only glucose, fructose or, to a lesser extent, sucrose support growth. Neither acid nor carbon dioxide is formed in detectable amounts. Citrate strongly inhibits growth and can be counteracted by magnesium. Marked inhibition of growth is caused if the ratio $[Na^+]/[K^+]$ is greater than 1; virtually no growth occurs if K^+ is entirely replaced (apart from the normal traces in the constituents of the medium) by Na^+. Carbon dioxide stimulates growth. Oxygen is normally tolerated up to a concentration of about 1 per cent; but growth is then weak and apparently involuted with individual cocci poorly differentiated to give chains with a more rod-like appearance.

Invariably, with the numerous isolates made so far of *S. pluton*, there have appeared colonies of *Bacterium eurydice*. The colonies of the latter have always been the first to appear, and its cultural characteristics agree with those given in detail by Gubler[8]. The two organisms will readily subculture together in mixed culture in anaerobic conditions on the medium described above. These mixed cultures (fifth subcultures) have repeatedly produced acute and extensive European foul brood when sprayed on the combs of brood in healthy bee colonies. The two organisms have always been re-isolated from the diseased larvæ of these colonies. Virulence seems to diminish markedly in subculture.

B. eurydice alone does not cause the disease, as previous workers have also shown. *S. pluton* in pure culture also has not usually caused the disease; the bacteria have appeared to grow vigorously in young larvæ but have disappeared in older larvæ after producing forms suggestive of the involuted types obtained in culture in relatively high oxygen tensions. On a few occasions an initially mild attack of the disease affecting very few larvæ has arisen after infection with pure cultures of *S. pluton*. However, *B. eurydice* was also seen to be present in the diseased larvæ and was always isolated, as usual, with *S. pluton*.

No evidence has been obtained to support the theory[5] that *B. eurydice* dissociates into *S. pluton* but it seems that the presence of both bacteria is necessary for the disease to appear. The appearance of *B. eurydice* in those larva which have shown disease after infection with pure cultures of *S. pluton* suggests that it was already present in the bees. Thi supports the findings of Burri[5] and Gubler[8] tha *B. eurydice* can occur in colonies of healthy bees. However, its occurrence does not appear to be widespread; at least not in the locality where the experiments reported here were carried out.

Further work on the symbiotic relationship between *B. eurydice* and *S. pluton* and upon th epidemiology and control of the disease is in progres and will be reported in more detail in due course.

Intrafollicular Cleavage of Human Ovum

In studies extending over the past four years on nore than four hundred human follicular and tubal va[1], three ova were found to have undergone leavage *in vivo* within the intact follicle, without any possible contact with spermatozoa. There was no evidence of any abnormal stimulation.

Follicular ova were obtained from ovaries *in situ* r immediately after their removal from patients undergoing gynæcological surgery. The unruptured ollicles were grossly normal in appearance and anged in size from 3 to 16 mm. in diameter. Aspiration of the follicles was accomplished with a sterile yringe and 20-gauge needle. The needle was inserted nto the ovarian tissue 3–4 mm. away from the edge f the follicle and then passed into its antrum so as o enter through the base, hence obviating any eakage of the follicular fluid. All normal-appearing ollicles were likewise aspirated in succession with he same syringe and needle, thus pooling the ova rom a given ovary. The fluid was then taken immeiately to the laboratory and expressed as a drop n a glass slide. A petrolatum ring was made around he drop and a cover-glass placed so that it touched he fluid but without direct pressure upon the ova. n order to have a petrolatum ring of uniform hickness, the petrolatum was expressed from a yringe through an 18-gauge needle without bevel. he ova were then studied by means of phase-conrast microscopy and photographed in phase contrast.

The ova which had undergone cleavage in the clear, traw-coloured follicular fluid included a 2-cell stage with two polar bodies within an intact zona pellucida, 4-cell stage with three polar bodies within an intact ona pellucida, and the blastula depicted in Fig. 1. he zona pellucida, completely denuded of the corona adiata and cumulus cells, surrounds a blastula of pproximately fifty cells. The exact number could ot be ascertained because of the difficulty in counting he cells in different focal levels in phase contrast. he cells, which differ in size partly because of synchronous cell division, surround the segmentation avity. Granules may be noted in the zona pellucida. The diameter of the blastula, to the outer surface of the zona pellucida, measured 150 microns.

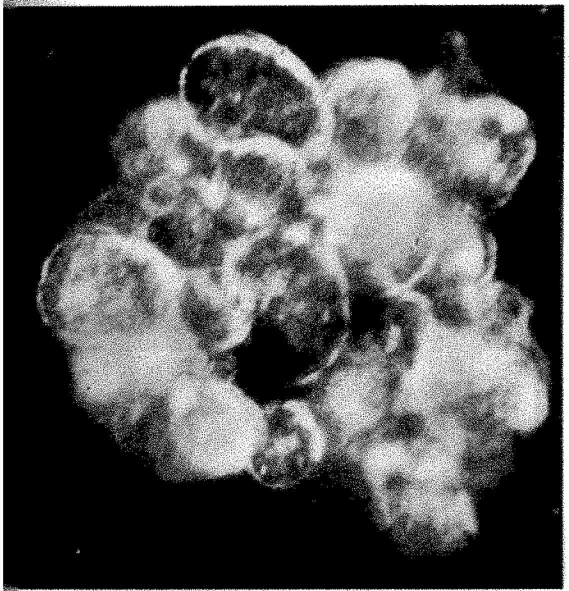

Fig. 1. Blastula stage of human ovum aspirated from intact ovarian follicle. (× *c.* 66)

In that ova from the different follicles were pooled, the exact size of the follicle which contained the blastula is not known. The specimen was obtained during the last half of the menstrual cycle. In comparison with normal human ova fertilized *in vivo* and recovered at pre-implantation stages of development[2], this blastula is approximately four days old.

The extremely rare occurrence of primary ovarian pregnancy in the human conceivably represents intrafollicular development of an ovum. From tissue properly prepared in such cases the haploid or diploid chromosomal content could be investigated. A study concerning the presence or absence of the sex chromatin body in the cells of a primary ovarian conceptus might aid in elucidating the origin of this type of gestation.

Continuing efforts are being made to record other intrafollicular developmental stages of the human ovum. Ascertainment of the chromosomal content is planned for any subsequent specimens.

Filaments of Silica

In the course of experiments with oxide compounds containing silica, fired in a wire-wound alumina tube furnace in a reducing atmosphere, filamentous deposits were formed.

On examination, they proved to be silica in the form of filaments of varying diameter, some of which were of approximately molecular dimensions. A typical electron microscope photograph is shown in Fig. 1. The filaments exhibited strong electrostatic charges and they would be attracted, from a distance of 1–1½ cm., to any material, organic or inorganic. The

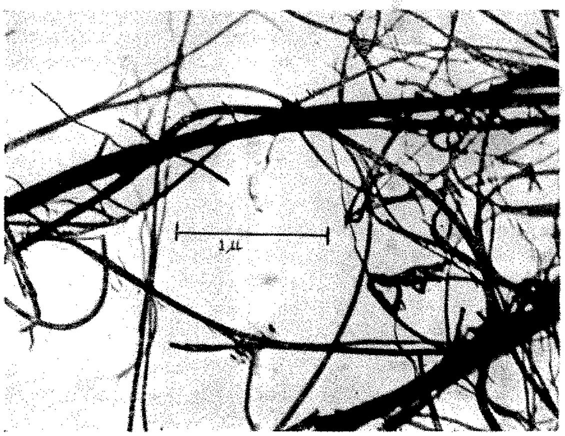

Fig. 1

charges decayed slowly and could not be detected six months later.

Use of Plastic Tubing in Chromatography

DURING a chromatographic separation of the carotenoid pigments of the starfish *Marthasterias glacialis* (L.) from Madeira, it was found that some pigment disappeared during elution, which was necessarily prolonged in order satisfactorily to separate the relatively large number of pigments present in the total carotenoid extract. Several pigments were lost in this way (presumably owing to oxidation on the column), and further, some of the zones were so small as to make it difficult to isolate them by extruding the column.

These difficulties were largely overcome by using a chromatographic column made in a tube of polyvinyl chloride instead of glass. This plastic is transparent, and during the time of chromatographic separation does not appear to react with the solvents used, such as light petroleum, diethyl ether, ethanol and methanol. The chief advantage of this type of column is that it may be cut easily and quickly with a razor as soon as the bands become distinct, thereby lessening much of the elution and consequent loss of pigment.

When adsorbents, added in a slurry, tend to adhere to the sides of the tube, they can easily be dislodged by tapping the flexible plastic.

By using such tubes, it was possible to isolate eight carotenoids from the aboral integument of this starfish.

Causes of Eskimo Birth-rate Increase

IN a recent article on "Researches in the Arctic Ocean"[1] dealing with Dr. G. E. MacGinitie's recent zoological work at Point Barrow, Alaska, a paragraph is of particular interest to me as an anthropologist who has spent time, off and on, at Barrow since 1908.

It reads: "The Eskimo birth-rate is increased as much as threefold when the arctic people eat 'white man's food' instead of their traditional pure animal diet of whale, fish and seal. When hunting was the only means of subsistence, Eskimo women became pregnant only once in several years; but with the new diet they bear a baby about every year".

There is no doubt that the Barrow diet has changed, along the lines indicated by Dr. MacGinitie, and that there has been such increase of birth-rate as he says. But another change, which is not mentioned there, has also been suggested as pertinent, namely, that Eskimo mothers used to nurse their children up to ages of three and four years; while now, under white tutelage, they nurse them for only about as many months.

When I was first at Barrow, forty-eight years ago, there was in residence for the Presbyterian Church a medical missionary, Dr. H. R. Marsh, who was ther on his second assignment, having been there severa years before going out on a leave which he spen at medical schools. Dr. Marsh stated the facts abou as Dr. MacGinitie does; but his explanation wa different: That women do not readily conceive whil they nurse their babies; and he believed the previously normal three-year spacing of births had bee reduced to a yearly one chiefly through the adoptio of the white man's style of early weaning.

While my observation as to the usual three-yea spacing agrees with those of Dr. MacGinitie and Dr Marsh, I noted many exceptions to that rule durin the eleven years I spent with Alaskan and Canadia Eskimos. The most striking case was that of a inland couple who looked to me around forty. The told me they were the parents of eleven children, non of whom had been twins; nine of these were stil living, they said, the other two having died at o soon after birth. When I learned this, my chie interest was in the size of the family. It was th largest that anybody had heard of; and, engrosse with this, I neglected inquiring about spacing. Sinc these were 'uncivilized' people, there is no doubt th mother nursed each child until the next came; an she may have nursed her previous along with th current baby, as I often saw done. Neither is ther any doubt that these parents of eleven had produce them while living on Dr. MacGinitie's traditional pur animal diet (which was never strictly pure in norther Alaska after 1880).

Perhaps both Dr. MacGinitie and Dr. Marsh ar partly in the right. Moreover, perhaps other factor than change in eating and nursing habits should b invoked to help explain the undoubtedly higher birth rate; for many and profound have been the change at Barrow since Dr. John Simpson first describe these Eskimos a century ago.

"Automation Economics"

MR. AUSTEN ALBU's reply to my protest agains having been misrepresented in his review of my boo "The Economic Consequences of Automation" (Octo ber 13, p. 816) contains two further misrepresenta tions in a single sentence. He attributes to me th view that "all steps taken to increase productio are inflationary"; and states that on p. 84 of m book I claim that "the effect of automation is . . to reduce the extent of inflation". I must emphaticall disclaim having held or expressed these views, bot of which are incorrect.

What I did say was that an increase of productio is inflationary if it means an increase in the *aggrega* cost of production. In quoting me as having sai that automation reduces the effect of inflation, M Albu omitted my all-important reservation "othe things being equal".

PAUL EINZIG

120 Clifford's Inn,
London, E.C.4.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, November 19

UNIVERSITY OF LONDON (at the Institute of Education, Malet Street, London, W.C.1), at 5.30 p.m—Mr. A. O. Chesters: "The Approach to 'Science for Young Children'".* (Seventh of eight ectures on "Problems of the Junior School". Further lecture on November 26.)

Tuesday, November 20

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p m.—Dr. J. S. Wilkie: "Mendel and Galton: Founders of the Scientific Study of Heredity".*

CEMENT AND CONCRETE ASSOCIATION (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. J. A. Banks: "Allt-na-Lairige Prestressed Concrete Dam".

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENT AND CONTROL SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Data Processing Equipment for Experimental Work; a Review of Techniques and Methods", opened by Dr. M. V. Wilkes.

Tuesday, November 20—Wednesday, November 21

INSTITUTION OF GAS ENGINEERS (at Church House, Westminster, London, S.W.1)—22nd Autumn Research Meeting.

Wednesday, November 21

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. V. Wynn: "Salt and Water Metabolism".*

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. A. Dickson Wright: "Quacks Through the Ages".

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. G. D. Nicholls: "Autometasomatism n the Lower Spilites of the Builth Volcanic Series"; Dr. C. D. V. Wilson: "Seismic and Gravity Investigations in the Vale of Clwyd, North Wales".

INSTITUTION OF POST OFFICE ELECTRICAL ENGINEERS (in the Conference Room, 4th Floor, Waterloo Bridge House, London, S.E.1), at 5 p.m.—Mr. F. C. Mead: "Some Problems Arising in the Technical Education of P.O. Engineering Staff".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Discussion meeting on "Climatic Change with special reference to the Period of the Instrumental Record".

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Dr. T. Barna: "The Replacement Cost of Fixed Assets in British Manufacturing Industry in 1955".

ROYAL MICROSCOPICAL SOCIETY (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. D. Lacy: "Studies on the Neurones of Patella Vulgata by Light and Electron Microscopy".

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMISTRY GROUP in the restaurant room of "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion Meeting on "The Micro-Determination f Sulphur".

BRITISH PSYCHOLOGICAL SOCIETY (joint meeting of the MEDICAL and SOCIAL PSYCHOLOGY SECTIONS, at the Royal Society of Medicine, Wimpole Street, London, W.1), at 8 30 p.m.—Symposium on "Anthropological, Psychometric and Psychotherapeutic Aspects of Homosexuality".

Wednesday, November 21—Thursday, November 22

IRON AND STEEL INSTITUTE (at 4 Grosvenor Gardens, London, S.W.1)—Autumn General Meeting.

Thursday, November 22

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. W. B. Emery: "Archaic Egypt—Recent Discoveries at Sakkara".*

UNIVERSITY OF LONDON (at Bedford College, Regent's Park, London, N.W.1), at 5.15 p.m.—Prof. B. C. King: "Some Problems of Igneous Geology in Southern Africa".*

CHADWICK TRUST (at the Royal Society of Health, 90 Buckingham Palace Road, London, S.W.1), at 5.30 p.m.—Dr. P. A. Raffle: "The Health of the Worker"* (Chadwick Public Lecture).

CEMENT AND CONCRETE ASSOCIATION (at the Institution of Strucural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Dr. F. W. Gifford and Mr. A. M. Janhunen: "The Design and Construction for the Prestressed Concrete Hangars at Helsinki".

INSTITUTION OF ELECTRICAL ENGINEERS, EDUCATION DISCUSSION CIRCLE (at Savoy Place, London, W C.2), at 6 p m.—Discussion on The Presentation and Demonstration of the Theory of Semi-Conductors o Students of Electrical Engineering", opened by Mr. P. Godfrey.

ROYAL AERONAUTICAL SOCIETY (at the Institution of Mechanical ngineers, Birdcage Walk, London, S.W.1), at 6 p.m.—Mr. L. P. oombes: "Aeronautical Development in Australia and Its Potential Value to the British Commonwealth" (Twelfth British Commonwealth and Empire Lecture).

Thursday, November 22—Friday, November 23

BRITISH NUCLEAR ENERGY CONFERENCE (at the Central Hall, Westminster, London, S.W.1), at 10 a.m. daily—Symposium on "The Calder Works Nuclear Power Plant".

Friday, November 23

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. J. R. Whinfield: "New Fibres". (Seventh of ten University Extension Lectures on "Technology and Industry". Further lectures on November 30, December 7 and 14.)

ROYAL AERONAUTICAL SOCIETY, GRADUATES' AND STUDENTS' SECTION (at 4 Hamilton Place, London, W.1), at 7.30 p.m.—Mr. A. W. Kitchenside: "The Effects of Kinetic Heating on Aircraft Structures".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. R. L. Wain: "Plant Growth and Man-made Molecules".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SENIOR LECTURER (preferably with good academic and research qualifications) IN ORGANIC CHEMISTRY—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (November 24).

BIOCHEMIST (B.Sc.) AT THE WALLACEVILLE ANIMAL RESEARCH STATION, New Zealand Department of Agriculture, to study trace elements and their relation to disease in farm animals—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. No. A.3/4/59 (November 30)

RESEARCH FELLOW to investigate certain pharmacological or biochemical aspects of cardio-vascular disease—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (November 30).

ASSISTANT EXPERIMENTAL OFFICER (with a pass B.Sc. degree or equivalent) IN THE DEPARTMENT OF POTATO GENETICS, for general maintenance of stocks and tests of resistance of tuberous *Solanums*—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford, Herts (December 1).

ASSISTANT LECTURER IN VETERINARY MEDICINE—The Registrar and Secretary, The University, Bristol (December 1).

LECTURER, Grade II, IN CHEMICAL PATHOLOGY in the Veterinary School—The Registrar and Secretary, The University, Bristol (December 1).

LECTURER (graduate in medicine or science, and postgraduate experience in some branch of physiology) IN PHYSIOLOGY in the Faculty of Medicine, University of Birmingham—The Assistant Registrar, Medical School, Birmingham 15 (December 1).

RESEARCH ASSISTANT (with a B.Sc. honours degree and a knowledge of either magnetic measurements, mineralogy or crystallography) for research into structures and magnetic properties of substances of geomagnetic interest—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (December 1).

LECTURER (preferably with a major interest in heat transfer, and a knowledge of some aspect of nuclear engineering) IN ENGINEERING (MECHANICAL)—The Registrar, The University, Manchester 13, (December 3).

SCIENTISTS (with a good honours degree in engineering or physics and the ability to handle data and to write clear concise reports) IN THE OPERATION RESEARCH GROUP at London Headquarters, to study problems of production and mechanization—The National Coal Board, Staff Department, Hobart House, London, S.W.1, quoting X/463 (December 3).

LECTURER OR ASSISTANT LECTURER (preferably with special interests in the chemistry of heterocyclic compounds) IN ORGANIC CHEMISTRY—The Registrar, King's College (University of London), Strand, London, W.C.2 (December 7).

ASSISTANT EXPERIMENTAL OFFICER (graduate with mathematical ability and biological interests) to work on the interpretation of data from horticultural experiments—The Secretary, East Malling Research Station, near Maidstone, Kent (December 8).

LECTURER IN FUEL TECHNOLOGY AND CHEMICAL ENGINEERING—The Registrar, The University, Sheffield (December 8).

DEPUTY PRINCIPAL (with a university degree in forestry or equivalent, together with practical and administrative experience in forestry) OF THE AUSTRALIAN FORESTRY SCHOOL, Canberra, Australia—The Official Secretary, Commonwealth of Australia, Australia House, Strand, London, W.C.2 (Australia, December 13).

SENIOR LECTURER IN PHILOSOPHY at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 17).

PLANT BREEDER (with a university honours degree in science or agricultural science and two or more years research experience) WITH THE DIVISION OF PLANT INDUSTRY, Commonwealth Scientific and Industrial Research Organization, Canberra, to initiate independent studies in the breeding of pasture plants—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 130/292 (December 19).

CHAIR OF CHEMICAL PATHOLOGY—The Registrar, The University, Leeds (December 31).

LECTURER (honours graduate in engineering, with practical experience) IN PETROLEUM PRODUCTION ENGINEERING—The Registrar, The University, Birmingham (January 1).

ASSISTANT LIBRARIAN (preferably science graduate, with either a recognized library qualification or experience in library work) at the Imperial College of Tropical Agriculture, Trinidad, B.W.I.—The Secretary, Imperial College of Tropical Agriculture, 40 Norfolk Street, London, W C.2 (January 15).

DIRECTOR (with a good honours degree and considerable research experience in physical or organic chemistry or in technology) of SUGAR RESEARCH, Department of Sugar Chemistry and Technology, Imperial College of Tropical Agriculture, Trinidad, B.W.I.—The Secretary, Imperial College of Tropical Agriculture, 40 Norfolk Street, Strand, London, W.C 2 (January 15).

ENTOMOLOGIST (with an honours degree in zoology and training in entomology, and preferably with experience in the control of insect pests occurring in the tropics, especially those attacking sugar cane)—The Director, Mauritius Sugar Industry Research Institute, Reduit, Mauritius (January 17).

ASSISTANT, Grade B (preferably with a knowledge of zoology) IN BOTANY—The Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham.

ASSISTANTS, Grade B (2), TO TEACH PHYSICS—The Principal, Technical College, Queen Street South, Huddersfield.

BIOCHEMIST or SENIOR BIOCHEMIST TO TAKE CHARGE OF THE ENDOCRINOLOGY LABORATORY concerned with clinical research in the treatment of cancer—The House Governor, Royal Marsden Hospital, Fulham Road, London, S.W.3.

BIOCHEMIST (with a science degree of a recognized university and special experience in medical biochemistry) IN THE MINISTRY OF HEALTH, Gold Coast Local Civil Service, to take charge of the Biochemistry Division of the Medical Research Institute—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.117/13/042.

BRADFORD DYERS' ASSOCIATION RESEARCH FELLOW (with high qualifications in science) to undertake research in tinctorial chemistry, textile chemistry or an allied subject—The Director of Education, Technical College, Bradford.

ELECTRONICS TECHNICIAN (with keen practical interest in electronics, and theoretical knowledge up to higher national or equivalent) to construct apparatus associated with a 2-million volt electron accelerator and other special electronics equipment for research—The Director, Radiobiology Research Unit, Mount Vernon Hospital, Northwood, Middlesex.

ENTOMOLOGIST (with an honours degree in natural science and specialized training and experience in entomology) IN THE MEDICAL DEPARTMENT, Western Region of Nigeria (H.M. Oversea Civil Service) to advise on, and supervise mosquito control measures in towns and rural areas in the Region, and carry out surveys on distribution and epidemiological importance of other insect vectors of disease—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.117/410/07.

GEOCHEMIST (with a good honours degree in chemistry or equivalent and some experience in inorganic analysis, with special reference to rock and mineral analysis) IN THE GEOLOGICAL SURVEY DEPARTMENT, Government of Tanganyika, for the analysis of rocks, minerals and ores, and the supervision of junior staff in routine analytical work—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/8/09.

HEAD (with a good honours degree and experience in the direction and administration of metallurgical research, either academic or industrial) OF THE METALLURGY DIVISION, for work in London and Sheffield which includes both fundamental and applied research into the general and physical metallurgy of iron and steel—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "H.M D".

LECTURER or SENIOR LECTURER IN MATHEMATICS; and LECTURERS or SENIOR LECTURERS (3) IN PHYSICS AND MECHANICS, at Britannia R.N. College, Dartmouth—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting Ref. No. 4641/56/7.

LECTURER (with special qualifications in physical chemistry and preferably with experience and/or knowledge of spectroscopy and colorimetry) IN CHEMISTRY at the Technical College, Bradford—The Director of Education, Town Hall, Bradford.

PHYSICAL and INORGANIC CHEMISTS (preferably with H.N.C (chemistry) or a general degree, or at least H.S.C. (science), Inter B.Sc. or equivalent), to engage in research on a variety of interesting and novel projects which include the chemistry related to reactors and the chemistry of inorganic and organic phosphors—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 1314/34.

PHYSICIST or ENGINEER (with at least a second-class honours degree or equivalent, and two years' postgraduate experience) for work involving the investigation of engineering problems connected with the deterioration of electrical insulation in service—The Personnel Officer, Electrical Research Association, Thorncroft Manor, Dorking Road, Leatherhead, Surrey.

RESEARCH ASSISTANT (with a good degree in horticulture or botany) for work on the physiology of flowering in carnations—Prof. R. H. Stoughton, Department of Horticulture, The University, Reading.

RESEARCH FELLOW (graduate in physics or engineering) IN THE COMPUTER LABORATORY, for investigations concerned with the input and output equipment of digital computing machines—The Secretary, Birkbeck College, Malet Street, London, W.C.1.

SENIOR LECTURER IN MARKET GARDEN AND GLASSHOUSE CROPS—The Clerk to the Governors, Essex Institute of Agriculture, Writtle, Chelmsford, Essex.

SENIOR TECHNICIAN IN THE ZOOLOGY DEPARTMENT, University of London—The Secretary, Royal Holloway College, Englefield Green, Surrey.

SOIL CONSERVATION OFFICERS (under 45, with a university degree involving specialization in soil conservation, or a university degree in agriculture or related subject, with at least two years postgraduate study or experience of soil conservation) in the Gold Coast Local Civil Service, for duties connected with land-use and anti-erosion measures—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/13/04.

TEACHER (with a good degree in physiology, preferably also with experience in pharmacology) IN PHYSIOLOGY in the Department of Biology—The Registrar, College of Technology and Commerce, The Newarke, Leicester.

Lubrication of Bearings

By F. T. BARWELL, Ph.D., B.Sc. (Eng.), Wh.Sc., M.I.Mech.E.
D.S.I.R. Mechanical Engineering Research Laboratory.

A critical selection of the more significant researches published over the last fifty years presented in such a form as to present a review of progress for the research worker, and a reference book for the engineer. It presents in a single volume such data as will assist in the design of bearings and similar components in the kinematic chain in accordance with modern knowledge.

A procedure for bearing design is described which has not appeared elsewhere and which enables journal bearings to be proportioned by the application of simple formulae. Price 50*s*.

Flow of Gases Through Porous Media

By P. C. CARMAN, M.Sc., Ph.D., Chief Research Officer, National Chemical Research Laboratory, South African C.S.I.R.

This text provides an integrated and, as far as possible, quantitative account of the flow processes involved when gases flow into or through fine-pored media. It has been designed for readers requiring a connected account of our present state of knowledge on the subject, discussing both theory and experimental methods, rather than those interested in specific technical applications. *Price* 30*s*.

Biochemical Problems of Lipids

Edited by G. POPJÁK and E. LE BRETON

This volume contains the Proceedings of the Second International Conference on Biochemical Problems of Lipids held at the University of Ghent in July, 1955.

Some 80 papers were read and discussed and have been collected in this volume, which has been arranged in four sections: (1) physical and chemical properties, methods of separation, and structures of lipids. (2) metabolism and biosynthesis, enzyme systems. (3) phospholipids and transport. (4) miscellaneous problems. *Price* 70*s*.

Descriptive leaflets on these new books, giving full lists of contents, available from:

OFFICIAL APPOINTMENTS

MAURITIUS SUGAR INDUSTRY RESEARCH INSTITUTE

Applications are invited for the post of Entomologist. Candidates must have obtained an honours degree in zoology with training in entomology Experience in the control of insect pests occurring in the tropics especially those attacking sugar cane is desirable Terms of appointment· On agreement for three years in the first instance with prospects of permanent employment thereafter Salary according to qualifications and experience in the range Rs.18,000 to Rs 24,000 per annum (£1,350 to £1,800 approximately). Compulsory pension contribution of 5 per cent of salary to the Mauritius Sugar Industry Pension Fund. Free passages on appointment and leave for officer, wife and children up to a maximum cost of three adult passages Six months' vacation leave after three years' service. Applications with proof of professional qualifications and the names and addresses of two referees must be sent by registered airmail to the Director, Mauritius Sugar Industry Research Institute, Reduit, Mauritius, so as to reach the addressee before January 17, 1957.

NEW ZEALAND DEPARTMENT OF AGRICULTURE

Vacancy No. 1715. Biochemist, Wallaceville Animal Research Station. Salary up to £1,250, as merited This is the ultimate maximum for an average officer but an outstanding officer may advance to £1,500 per annum. Qualifications desired: B Sc. Duties: The study of trace elements and their relation to disease in farm animals Generous travelling allowance for successful candidate and his family.

Application forms and conditions of appointment may be obtained on request from: High Commissioner for New Zealand, 415 Strand, London, W C.2, mentioning this paper and quoting reference number A3/4/59. Completed applications to be lodged in London not later than November 30, 1956

EXPERIMENTAL OFFICERS AND ASSISTANT Experimental Officers in various Government Departments. The Civil Service Commissioners invite applications for pensionable posts The posts are divided between following main groups and subjects (a) Mathematical and Physical Sciences, (b) Chemistry and Metallurgy, (c) Biological Sciences, (d) Engineering subjects, and (e) Miscellaneous (including, e g , Geology, Library and Technical Information Services). The Nature Conservancy employs Assistant Experimental Officers and is concerned with ecological research. Age limits· For Experimental Officers, at least 26 and under 31 on December 31, 1956; for Assistant Experimental Officers at least 18 and under 28 on December 31, 1956 Extension for regular service in H M. Forces. Candidates aged 31 or over with specialized experience for Experimental Officer posts may be admitted Candidates must have at least one of a number of specified qualifications Examples are higher school certificate, general certificate of education, Scottish leaving certificate, Scottish universities preliminary examination, Northern Ireland senior certificate (all in appropriate subjects and at appropriate levels), higher national certificate, university degree Candidates taking their examinations in 1956 may be admitted Candidates without such qualifications may be admitted exceptionally on evidence of suitable experience. In general a higher standard of qualification will be looked for in the older candidates than in the younger ones Salary (London) Experimental Officer, £925 to £1,135 (men), £836 to £1,015 (women) Assistant Experimental Officer, £365 (at age 18) to £805 (men), £715 (women) Starting pay up to £655 (men) or £627 (women) at 26 or over. Somewhat lower outside London Promotion prospects Women's scales being improved under equal pay scheme. Opportunities for further education.—Further particulars from Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W 1, quoting No S 94-95/56. Early application advised and in any case not later than December 31, 1956

UNIVERSITY OF LONDON, KING'S COLLEGE, will require on January 1, 1957, or as soon thereafter as possible, a Lecturer or Assistant Lecturer in Organic Chemistry, preferably with special interests in the chemistry of heterocyclic compounds. Salary· Lecturer, £700 by £50 to £1,000, £1,050 by £50 to £1,400; Assistant Lecturer, £600 to £650 to £700, with family allowances and superannuation benefits in each case.—Particulars and application forms from the Registrar, King's College, Strand, W.C 2, whom complete application forms must reach by December 7

COMMONWEALTH of AUSTRALIA
DEPARTMENT OF SUPPLY
DEFENCE STANDARDS LABORATORY
ALEXANDRIA, N S.W.

Applications are invited for a temporary position of Scientific Officer, Grade 1, at the above Laboratories. Salary £A.1,287 to £A 1,602 per annum Duties. Research into problems associated with the production of protective coatings on metals by electrochemical means and with the evaluation of such coatings for effectiveness and serviceability as corrosion barriers. Qualifications. first-class honours degree with chemistry as a major subject. Whilst the position is a temporary one, the tenure of employment is not limited Under specified conditions, first-class boat fare (if first-class berth is available) for the appointee and dependants (wife and dependent children) will be paid by the Commonwealth

Application forms obtainable from The Senior Representative (AP 70), Department of Supply, Australia House, Strand, London, W C.2, with whom applications should be lodged by December 22, 1956

UNIVERSITY OF SHEFFIELD

Applications are invited for Three Research Fellowships in Metallurgy which are offered to graduates with research experience who desire an opportunity to do metallurgical research on a subject of their choice.

THE J. H ANDREW RESEARCH FELLOWSHIP
THE UNITED STEEL COMPANIES' RESEARCH FELLOWSHIP
THE TUBE INVESTMENTS RESEARCH FELLOWSHIP

The subject for the research will be chosen in consultation with the Professor of Metallurgy, and in the case of the Andrew and United Steels Fellowships should lie broadly in the field of ferrous metallurgy. Normal tenure will be five years but the appointment will be for two years in the first instance and thereafter will be renewable annually. In each case the stipend for the first year will not be less than £750 per annum, and will rise by annual increments of £50 to £950 A higher stipend will be paid to a candidate with exceptional qualifications. There will be superannuation provision under the F S S U.

Applications (three copies), including the names and addresses of referees and, if desired, copies of testimonials, should reach the Registrar (from whom further particulars can be obtained), not later than December 31, 1956.

UNIVERSITY OF LEEDS

Applications are invited for a Postdoctoral Fellowship in the Department of Physical Chemistry, of tenure up to three years, starting salary not less than £600 per annum and annual increments of £50 per annum. Applicants should hold a Ph.D. degree in physical chemistry and have experience either of high polymer chemistry or in reaction kinetics. The date of taking up the appointment could be arranged to suit the convenience of the Fellow appointed, but will not be later than October 1, 1957.

Applications, together with the names of two referees, should be sent to Professor F. S Dainton, School of Chemistry, The University, Leeds, 2, not later than January 1, 1957

UNIVERSITY OF SHEFFIELD

Applications are invited for a post of Lecturer in Fuel Technology and Chemical Engineering, to begin duties on January 1, 1957, or as soon as possible thereafter Salary scale, £650 by £50 to £1,350 with F.S S U provision and family allowance Initial salary according to qualifications and experience

Further particulars may be obtained from the Registrar, to whom applications (five copies), should be sent by December 8, 1956

UNIVERSITY OF MELBOURNE
AUSTRALIA

Applications are invited for a position of Senior Lecturer or Lecturer in Geology The lecturer may be required to lecture on elementary general geology and special knowledge of mineralogy, economic geology, or similar subjects would be desirable The salary will be determined according to qualifications and experience in the following ranges. Senior Lecturer, £A 1,850 to £A 2,150 per annum , Lecturer, £A 1,300 to £A 1,800 per annum. Superannuation similar to F.S S U. will be provided.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London. W C 1 The closing date for the receipt of applications, in Australia and London, is December 31 1956

AUCKLAND HOSPITAL BOARI
NEW ZEALAND

Applications are invited from those with t necessary qualifications for the position Physics Technician to the Radiotherapy Depa ment, Auckland Hospital. The work will inclu the construction of devices of a precision natu in addition to general duties in maintaining de X-ray therapy units Applicants should have good technical background, should be resource and able to undertake instrumental desig Salary will be determined within the follow scales according to the qualifications and expe ence of the appointee: Grade (1), £N Z 860 £N Z.880 to £N Z 900; Grade (2), £N.Z 780 £N Z.800 to £N Z 820 Details of payment travelling expenses to New Zealand are set out the conditions of appointment which, toget with explanatory memorandum and applicati forms may be obtained from the office of High Commissioner for New Zealand, N Zealand House, 415 Strand, London, W.C.2

Applicants must complete the official applicati form in duplicate, sending one copy to the afo mentioned High Commissioner's office and c copy to the Secretary, Auckland Hospital Boa Kitchener Street, Auckland, C 1, New Zealan Applications close with the above at noon Monday, December 31, 1956.

R. F. GALBRAITH,
Secreta

SENIOR SCIENTIFIC OFFICERS SCIE tific Officers. The Civil Service Commission invite applications for pensionable appointme covering a wide range of scientific research a development in most of the major fields of fund mental and applied science. In biological su jects the number of vacancies is small· Individ vacancies exist in the Natural History Muse for candidates who have special knowledge or who are interested in, malacology, helmintl logy, acarology, mammalian taxonomy, taxonor botany (monocotyledons), x-ray crystallograp Candidates must have obtained a university gree with first- or second-class honours in appropriate scientific subject (including engine ing) or in mathematics, or an equivalent qua fication , or possess high professional attainmen Candidates for Senior Scientific Officer po must, in addition, have had at least three yea postgraduate or other approved experience A Limits· Senior Scientific Officers, between 26 a 31, but specially suitable candidates under 26 m be admitted; for Scientific Officers, between and 28 during 1956 (up to 31 for perman members of the Experimental Officer cla Salary (London) Senior Scientific Officers: (m £1,135 to £1,345; (women) £1,026 to £1,2 Scientific Officers: (men) £605 to £1,055; (wom £605 to £962. Women's scales being improv under equal pay scheme. Somewhat lower ra in the provinces —Further particulars from Ci Service Commission, Scientific Branch, 30 (Burlington Street, London, W.1, quoting N S 53/56 for Senior Scientific Officers and S. 56 for Scientific Officers Interview Board at intervals, as required. Early application a vised and in any case not later than December 1956

RESEARCH ENGINEERS REQUIRED N C B's Coal Research Establishment at St Orchard, near Cheltenham, Glos , to deve plant for the manufacture of smokeless and met lurgical fuels The work is varied and will the first instance be concerned with the des of automatic machines for a new briquetting p cess. Good honours degree or equivalent qua fication required; an interest in the fundamen aspects of engineering together with research perience is desirable Appointments (superann able) as either Scientist 1 (£1,275 to £1,650 ma or Scientist 2 (£925 to £1,300 male) according qualifications and experience (Ref No X 46 Scientific Technical Officers also required to as with the above work. Appointments (superan able) as either Scientific Technical Officer 2 (£ to £785 male) or Scientific Technical Officer (£440 to £600 male) according to qualificati and experience (Ref No 468)—Write, with particulars of age, education, qualifications a experience, to National Coal Board at above a dress, marking envelope with relevant referen number before November 24, 1956

BIRKBECK COLLEGE (UNIVERSITY London) Research Assistant required for search into structures and magnetic properties substances of geomagnetic interest. Candida should have B Sc. honours degree with knowle of either magnetic measurements, mineralogy crystallography. Salary up to £600 according qualifications and experience.—Applications Secretary, Birkbeck College, Malet Street, Lond W C.1, before December 1

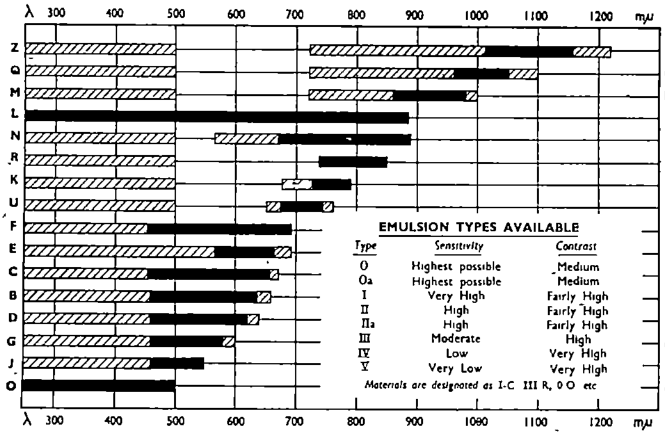
Make a note now . . .

When no existing photographic plate will meet your requirements, try a 'Kodak' Scientific Plate made to a special formula. There are 90 of these—90 selected combinations of colour-sensitizing class and emulsion type. They are supplied to your special order—a service well worth noting should you have difficulty in finding the right plate.



EMULSION TYPES AVAILABLE

Type	*Sensitivity*	*Contrast*
0	Highest possible	Medium
0a	Highest possible	Medium
I	Very High	Fairly High
II	High	Fairly High
IIa	High	Fairly High
III	Moderate	High
IV	Low	Very High
V	Very Low	Very High

Materials are designated as I-C III R, 0 O *etc*

Other 'Kodak' Scientific Plates cover specific laboratory requirements:—

'Kodak' Uniform-Gamma Plate. Used in ultra-violet spectrography to obtain a more uniform contrast over the spectral range 250-400mμ. Not stocked—available to order.

'Kodak' Autoradiographic Plates: Dry-stripping materials for the preparation of autoradiographs. Two types are available—*'Kodak' Fine-Grain Autoradiographic Stripping Plate AR. 10* and *'Kodak' Fast Autoradiographic Stripping Plate AR.50.* Both are stocked and are available only in 4¾ x 6½ in. size.

M.R. 'Kodak' Maximum-Resolution Plate. Specifically produced for very high resolution photography, for graticule production and for X-ray micrography. Stocked in 2 x 2 in., 3¼ x 4¼ in., 4¾ x 6½ in., and 9 x 12 cm. sizes. Other sizes available to order.

Kodak *PHOTOGRAPHIC PLATES for SCIENCE and INDUSTRY*

Kodak Limited, Industrial Sales Division, Kodak House, Kingsway, London, W.C.2. *'Kodak' is a registered trade-mark*

MODEL 47A

MILLIOHMMETER

E·I·L

This transportable direct reading instrument is designed for the measurement of low and very low resistance from 1200 ohms down to 50 microhms. It is simple to operate, cannot be damaged by mis-use, and has a very wide range. No batteries are required, and the minimal heat dissipation does not exceed one-eighth of one watt.

SOCIAL ADJUSTMENT AND TECHNOLOGICAL CHANGE

A SIGNIFICANT feature of the debate on automation which Lord Macdonald of Gwaenysgor initiated in the House of Lords on October 23 was the emphasis placed on the social aspects of technology. It was clearly recognized that technical change is a social process as well as a technical one, and that if it is to proceed smoothly and the nation is to reap the full benefit that automation can offer, due attention must be given to the social problems involved. Here the greatest problems are, as Lord Hailsham emphasized when replying for the Government on the debate, in the field of education. Lord Hailsham said he doubts whether it has yet been realized what a profound impact the developments represented by automation will make upon the educational system of Britain, and he pointed out that this is as true of general education as of technical education.

What is equally important is that much research s still needed on various social and economic aspects of technical innovation. The report on automation ssued by the Department of Scientific and Industrial Research last May listed a number of specific topics on which research was in progress, many of these projects being financed at least in part by Conditional Aid funds derived from economic aid from the United States. When questioned as to the continuance of such investigations, Lord Hailsham admitted that uch funds are no longer available. He said, however, that it should not be assumed that the researches have also come to an end; but he gave no indication as to the scale on which such investigations would ontinue. This is still under consideration by the Department of Scientific and Industrial Research and by the Government; but it will certainly consort more with the dignity of Britain that work of such mportance should be financed out of her own resources. The Government should be pressed to provide adequate resources and to continue efforts to ensure that adequate use is made of the results already available.

Strong emphasis on the social problems of industry is to be found in the Messel Memorial Lecture which Sir Alexander Fleck delivered to the Society of Chemical Industry on October 12. Messel himself, ke Ludwig Mond, was deeply concerned with the onditions under which the people employed by him worked and lived, and he played an important part, t least on the intellectual side, in making the chemical ndustry contribute to social development. Sir lexander referred to this, and in reviewing the problems now facing the industry, he again placed is main emphasis on what should be done to enable hemical industry to serve more efficiently the social s well as the commercial needs of to-day. While, or example, he believes that we do not proceed so apidly as some other countries from the research tage to production, this may not be a disadvantage, rovided we take full advantage of that longer interval o secure the necessary social adjustment. On the other hand, it is possible that such relatively late production may involve serious loss of income and of profit which can affect the economic strength of the nation. The survival and even the strength of an industrial firm may to-day, as Mr. Tom Burns points out in a study of the social character of technology (*Impact of Science on Society*, September), be a matter of great concern to society as well as to the firm itself.

Here obviously is a field for further inquiry, and Sir Alexander also questioned whether our research is as well aimed as it might be. Still more important is the use the chemical industry makes of its personnel: the improvement in hours of work and working conditions already made do not absolve the industry from the need to keep its methods and conditions of work under constant review. Sir Alexander suggested that, with the continual growth of automatic controls and the tendency for work of a monitoring character to extend, it is a major problem how to maintain in such work both interest and satisfaction for men employed as factory payroll workers.

Here Sir Alexander believes that the development of the trade union system in Britain may provide a solution, though he suggested that real partnership between the less technically equipped members of the industry and the technically qualified requires a developing type of organization which in general has been, and is still, lacking in the different components of our industrial life. We need, both in the management components and in the trade union components, an organization which is flexible, capable of understanding current and impending changes, and willing, so far as lies in its power, to support changes which will be for the good of the industry and of the people employed in it. How far we are yet from such a position is sufficiently illustrated by the attempt to insist that the fireman of the steam locomotive shall be retained on a diesel engine, and by the attitude frequently displayed to the working of lodging turns on the railways. Such attitudes can only be overcome when a great organization takes real care to retain its contact with all its workers, rank and file as well as departmental heads; and shows itself concerned to secure their co-operation, ameliorate their conditions and make their lives more prosperous and content. Time is required to build up effective organization for this purpose; to foster understanding, co-operation and trust; Sir Alexander believes that works councils could do much to help here, all the more as they conform to no rigid pattern but can be adjusted and modified to meet the needs of any particular section of an industry.

Sir Alexander did not conceal the fact that the increase of automatic control and like changes tend to decrease the proportion of factory payroll workers to what is loosely called staff. This clearly of itself involves other problems of adjustment, of education and of change of occupation; and he stressed in conclusion that unless chemical and other industries are to work in a geographical or in a cultural desert, much more care will have to be taken that their operation is constructive and not destructive. To his mind, this can only be secured by sociological advance on many fronts—by profit-sharing schemes, capital participation, cultural participation in art, but above all through a general advance in the educational level of the bulk of the population.

The aspect of service was a dominant note in this striking address, and the sense of social responsibility in it may contribute largely to the solution of the human problems of management which Sir Alexander emphasized afterwards in addressing the Textile Institute on "Change in Industry" on October 26. Discussing the role of the scientist or technologist in industry, he pointed out that while technical judgment is required at all levels of management, there are human problems also; and management must provide leadership and inspiration as well as technical control. The judgment and high qualities of industrial statesmanship required are by no means solely to be found in those with technical qualifications; but he believes that the presence of the technical man in management has been a material factor in the expansion of the chemical industry and one that could contribute increasingly to the conflict of ideas that keep minds awake and receptive of new ideas so that progress is ensured.

It is interesting to note that while the conception of service finds a minor place in the symposium on science and social responsibility which forms the third in the series "Science and the Affairs of Man" appearing in the *Bulletin of the Atomic Scientists* in its tenth anniversary year, the note of responsibility is strongly sounded. It is equally to be found in the article "Science and Our Times" which Dr. J. R. Oppenheimer contributes to the same issue of the *Bulletin* (September 1956). Dr. Oppenheimer points to the grave problems of good and evil which increasing advances in the biological sciences and in our understanding of man's psyche, his beliefs, his learning, his memory and his probable action will involve. Unless we learn to use the new and more certain knowledge of man's behaviour, the danger will remain that we may not only suffer material destruction but also lose much of our human inheritance—much that has enriched our civilization and our humanity.

While Dr. Oppenheimer is hopeful that, despite the opportunities we have already missed, we may find new opportunities of creating honest and viable international communities with increasing common knowledge and understanding, he urges that, if the free world is to remain free, we must maintain the opportunity for a man to learn anything. Indeed, argues Dr. Oppenheimer, we must, in a world in which the changes wrought by the application of science and the din of communication complement the unhingeing effects of the explosive growth in knowledge itself, cherish man's curiosity, his understanding and his love, so that he may truly learn what is new and hard and deep. The world that we study and in which we work is, as he observes, an orderly world; but it has no central chamber of common understanding or common repository of essential knowledge. It is a world united by countless bonds and it may well be the beginning of wisdom to cultivate the virtues, the restraint and tolerance, the sense of fraternity that are asked of us, if in this modern world we are to live not in chaos but in community.

Dr. Oppenheimer was looking to a larger background than Sir Alexander Fleck, but what he says of the impact of science on the modern world as a whole is equally true of its impact on the more limited world of industry, and is remarkably in line with what Sir Alexander urged in his Messel Memorial Lecture. Like Eugene Rabinowitch in his paper, "History's Challenge to Scientists", contributed to the September issue of the *Bulletin of the Atomic Scientists*, Dr. Oppenheimer points to the responsibility of the scientist to contribute by education and persuasion as well as by political action to the rationalization of the behaviour of nations and of mankind; and in so far as industry is looked upon as a social as well as an economic process, the approach and the technique to be used will have much in common The keynote is education, and the sense of respons ibility, the ideal of public service, must be informed and guided by clear ideas not only of what is technically possible and desirable but also of mankind's great heritage. No narrow or partial view of life o of industry is likely to avoid disaster, and whethe or not the scientist finds a solution to his respons ibilities as a citizen in holism or not, as Prof. Alex ander Haddow suggests in his article on the scientis as citizen, the importance of an education in which men are trained to respect, understand and reverenc human values can scarcely be over-stressed at th present time.

It is this factor that Mr. Tom Burns appears inclined to overlook in the article on "The Socia Character of Technology" referred to earlier. H directs attention to two major changes in th social circumstances affecting the introduction c innovations. The first, already noted, is that th increase in the size of firms has made their surviva a matter of greater consequence to society than i ever was before; while the chances of a firm su viving are increased if the technical innovation which might render its processes or products obsolet are developed within it and not outside. The secon is a consequence of the scale of scientific and indu trial activity outgrowing the social institutions i which the industrial revolution originated, and of th departmentalism of science and the development c barriers between pure and applied science, an between science and industry. The production c invention and innovation tends to become randon and scientists and technical innovators have accord ingly tended to become organized in profession groups which overlap teaching and research instit tions, government departments and agencies, an industry. Mr. Burns does not think that eith change is complete; but he does suggest th innovation is the natural outcome of the work of number of professional technologists in applyi pecific techniques to solve the specific problems of a ser, and that it is not in any sense dependent on the fforts of individual entrepreneurs. It will increasingly ake place outside the firm itself; and technology, rganized as a specific social institution, is moving nore and more into a controlling position. Major hanges in the economic structure of society are ikely to be derived more from the expansion in size nd power of the technological system than from vert political strategies.

Mr. Burns's view of technology as a system xtraneous to industry, yet essential to the survival f individual firms, and of the technologist as a nember of a social system, independent of the factory vorkshop, industrial development laboratory, government research establishment and university labortory, in which he is closely integral and professionlly organized, may be challenged on several grounds. t appears to take no account of the extent to which he technical service departments maintained by rogressive firms provide them with targets for esearch and stimulate technical innovation, nor of he extent to which technical innovation may itself lerive inspiration from advances in fundamental cience. He does, however, point to the importance f what is known as operational research and, by mplication rather than by explicit statement, he ppears to regard industry as a social activity the bjectives of which are determined by the needs of he community in which it operates and which it xists to serve. The technologist, as visualized by Ir. Burns, will be working largely in those conditions which Sir Alexander Fleck puts forward as conducive o wide views and open minds, and it will be noted hat Mr. Burns makes a strong plea that the techologist should move much more freely between osts in government, university and industrial establishments, as well as for effective communication not erely between technologists and scientists but also ith the ordinary citizen. This group of papers and ddresses shows how firmly the idea of social esponsibility has already taken hold of the indusialist and technologist; and it also indicates the nportance of greater attention to education at all vels, as well as the need for further inquiry into the any problems of social adjustment that technical nnovation brings and the need for due care in ealing with the social aspects of such developments oth inside and outside industry.

JAMES HUTTON AND JOHN PLAYFAIR

lustrations of the Huttonian Theory of the Earth y Prof. John Playfair. Facsimile reprint with an ntroduction by George W. White. Pp. xix+xx+ 28. (Urbana, Ill.: University of Illinois Press, 956.) 4.50 dollars.

N Greyfriars Churchyard in Edinburgh there is a memorial tablet inscribed: "James Hutton, .D., F.R.S.E. 1726–1797. The Founder of Modern eology". It is obvious that the emphasis in the last phrase is on the "modern", because stones and the Earth as a whole have been objects of study since time immemorial. Before Hutton, much had been written about minerals, rocks, mountains, springs, rivers, earthquakes and volcanoes, by naturalists and miners. The last decades of the eighteenth century saw the emergence of a new approach to these subjects by a few men working independently but contemporaneously—a new approach which, abandoning the idea of mere 'curiosity', sought to link all natural phenomena into a system and so created geology as an organized science. Of these 'founders of modern geology' the three principal were: the 'sage of Freiberg', Abraham Gottlob Werner, bringing order into minerals and rocks; the English surveyor, William Smith, bringing order into strata; and finally the Edinburgh medical doctor, James Hutton, bringing order into geological processes. This order consisted of a framework and of a method. The framework was the geostrophic cycle —the cycle of changes in the Earth, constantly transforming the materials and the surface of the Earth. The method was that of actualism, with its motto: "The present is the key to the past". The geostrophic cycle consisted of successive processes of weathering, denudation, transportation, deposition, consolidation of sediments, metamorphism, magmatism, folding and elevation of strata—this is the essence of Hutton's "Theory of the Earth". An important corollary was that each material was determined by a specific process and each specific process resulted in a certain material. This led to the method of actualism—to understand past formations we must understand modern processes. The frequently mentioned struggle between the Vulcanists and the Neptunists, as associated with the names of Hutton and Werner, is a mere ripple on the surface, a *succès de scandale*, as compared with the fundamental contributions to the science of geology made by these two men.

Unfortunately, all three—Werner, William Smith and Hutton—were clumsy writers and reluctant controversialists, and all three required valiant champions to fight their battles for them. In spite of occasional beauty of phrase, Hutton's "Theory of the Earth" is a difficult book to read and understand. Also, its publication in 1795 happened to fall in a period of reaction provoked by the excesses of the French Revolution. Hutton, in his lifetime and after his death, was violently attacked and accused of free-thinking. Now, we see Hutton in a different light. "My own opinion," writes Sir Edward Bailey, "is that Hutton's chief sin in the eyes of many of his contemporaries was his confident interpretation of God's purpose through thoughtful observation of Nature without accepting guidance from revelation." But the fact was that at the turn of the century Hutton's work was either unknown or derided, whereas Werner's ideas, some of them without any doubt excellent, were all-pervasive among the geologists. But a few decades brought a miraculous change, and Hutton's ideas now animated the infant science of geology. Visibly this transformation was due to the genius of Charles Lyell, whose "Principles of Geology" and "Elements of Geology", published during the 1830's, finally consolidated geology into an organized science. It was clear to some geologists, among them Fitton, that behind Lyell stood Hutton; and at first it is rather difficult to understand how Lyell in his letter to Fitton of August 1, 1839, referring to the latter's review of his "Elements" in which Fitton had given a clear account of the work of Hutton, could write: "It [Fitton's summary of Hutton's work] has been useful to me, as I found it difficult to read and remember Hutton, and though I tried, I doubt whether I ever fairly read more than half of his writings, and skimmed the rest". Later in the same letter, Lyell, while recognizing the value of Playfair in making Hutton's view better known, does not hide his own light under a bushel, for he writes: "yet as an admirer of Hutton all I could have wished is, that your panegyric on Hutton had appeared as aiding and seconding my efforts, since I trust that no book has made the claims of Hutton better known on the Continent of late years than mine".

The fact is that it was Playfair's book that gave Lyell all he wanted to know about Hutton's ideas. Playfair acted as a spokesman for Hutton, and one may say truly that without Playfair the progress of geology would have been retarded by many decades. John Playfair (1748–1819) was a great friend of Hutton. He was first minister at Benvie and Liff and afterwards professor, first of mathematics, and then of natural philosophy, in the University of Edinburgh. He belonged to the brilliant intellectual circle of the Athens of the North in her period of glory. As a great friend of Hutton, he began, after Hutton's death in 1797, to collect materials for writing his memorial, and this led him to a detailed study of Hutton's geological work, which, prompted by the attacks made on Hutton, he published in 1802 under the title "Illustrations of the Huttonian Theory of the Earth". In 1822 this book was republished in the "Works of John Playfair, Esq.". At the present time both editions are extremely difficult to obtain, and thus geologists and historians of science must welcome the newly published facsimile reprint of the Playfair's "Illustrations". It is a handsomely printed and bound quarto volume containing an introduction, a biographical sketch of James Hutton and a biographical sketch of John Playfair (pp. v–xix), all three of them written by George W. White, of the University of Illinois.

The "Illustrations" consist of two parts. The first part contains the illustrations proper or "a general outline of the system in one continued discourse" (pp. 1–140), containing the following sections and chapters: Section I, (1) materials of the strata, (2) consolidation of the strata, (3) position of the strata; Section II, (1) metallic veins, (2) whinstone, (3) granite; Section III, phenomena common to stratified and unstratified bodies. The second part, "Notes and Additions" (pp. 143–528), contains twenty-six notes dealing with various geological topics. They are of great interest, as they mark the extension of Hutton's horizon of experience and contain a certain amount of criticism of his views. It is a great pity that criticism was not applied to the most vulnerable part of Hutton's theory, namely, to his view that heat alone was responsible for the consolidation of strata.

This is not the place to discuss the merits and demerits of the Huttonian theory of the Earth or the interpretation of it by Playfair; but by reading the two authors in parallel, one can see that the success of Playfair's book was due not solely to his clarity of writing but also to a certain amount of simplification and to the elimination of what would be considered by his contemporaries as vague metaphysical background. The part omitted may have little value fo geology as such, but it is of interest to student of the evolution of human thought. Leaving thi aspect out of consideration, let us give only a smal sample of Playfair's clarification and simplificatior The passages quoted below refer to the idea tha great features on the Earth must be the products c great events, a favourite tenet of the school c catastrophists, to which both Hutton and Playfai were opposed. Here is Hutton: "But though, i generalising the operations of nature, we have arrive at those great events, which, at first sight, may fi the mind with wonder and with doubt, we are not t suppose, that there is any violent exertion of powe such as is required in order to produce a great even in little time; in nature, we find no deficiency i respect of time, nor any limitation with regar to power. But time is not made to flow in vain nor does there ever appear the exertion of supe fluous power, or the manifestation of design, nc calculated in wisdom to effect some general end (I, p. 182). And here is Playfair: "Time pe forms the office of *integrating* the infinitesime parts of which this progression is made up; collected them into one sum, and produces fror them an amount greater than any that can b assigned" (p. 117).

The success of Playfair's "Illustrations" wa due also to the presentation of Hutton's theor in such a way that it would conform to the ne scientific tradition, in which arrays of facts woul be used for the formulation of a tentative theory and final causes would have no place at al Looked at in this light, Hutton's achievemer must be valued very highly, especially if we cor sider his contribution to the application of the ide of development or evolution to the Earth. In th respect Hutton stands midway between Kant an Darwin.

All this shows that the present new edition Playfair's "Illustrations" should be welcomed by a interested in the history of scientific ideas. It als indicates an obvious gap in our book list—an easil available Hutton. The interpretation of Huttc being now published, what about the republicatic of the "Theory of the Earth"? The third volun by a strange irony of fate was lost in manuscript f more than a century, and when found was publishe in 1899. It would be most appropriate that tl "Commemorative Volume" of James Hutton, pul lished by the Royal Society of Edinburgh in 195 and the newly republished Playfair book should l followed by a facsimile edition of the "Theory of tl Earth". As an anticipation of the form it shou take, and as minor criticism of the present edition the "Illustrations", I might suggest that it shou have a good index of subjects, authors and localiti mentioned in the text, as well as notes throwing lig on the objects and phenomena described by tl author, some of which are described in such a w that their significance may escape the modern reade For example, Hutton (and Playfair) describe unco formity without mentioning this term, which w introduced in science later. Errata in the origir edition may be mentioned as well. For example, Playfair's book we have *Vinezia* instead of *Venez* (p. 133) and *Palasso* instead of *Palassou* (p. 344). mistake (corrected in the 1822 edition) is also ma in the numeration of the sub-sections—the numb 134 is duplicated (p. 138 and p. 143).

S. I. TOMKEIEFF

THE PHYSICS OF THE SOLID STATE

Solid State Physics

Advances in Research and Applications. Edited by Frederick Seitz and David Turnbull. Vol. 2. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1956.) 10 dollars.

THE second volume of "Solid State Physics" maintains the high standards set by the first. Moreover it contains matter which will be of interest to physicists and chemists who, although perhaps unable to distinguish an exciton from a donor level, wish to know something of the applications of nuclear magnetic resonance and neutron diffraction to structural and dynamical problems.

Six years ago G. E. Pake contributed a pair of excellent expository articles on nuclear magnetic esonance to the *American Journal of Physics*. They are now expanded and brought up to date in the first article of the present volume. The author gives very lear explanations of such vital concepts as line breadth and its associated 'spin-spin' relaxation time as well as the dynamically determined 'spin-lattice' relaxation time. Yet perhaps one can, without being hurlish, deplore the lack of a unified approach which recent theoretical work would seem to make possible. The newer techniques and discoveries are exciting nd are well explained. For example, the treatment given here of Hahn's 'spin echo' methods is much more asily understood than the original papers; this echnique is clearly important for investigating iffusion processes as well as relaxation times. An nteresting new development is that partial polarization of nuclei can be induced by saturating the lectron spin resonance of certain metals. Just as he polarization of electrons produces in any event a ight shift in the nuclear resonance frequency (disovered by Knight), so in turn does the nuclear olarization react on the electronic resonance and hift its frequency. Pake suggests that the latter shift hould be called the 'day shift', since it dawns as the Knight shift subsides.

W. D. Knight discusses his shift in considerable etail in the second article, on nuclear magnetic esonance in metals. The interest here is more pecialized. The effect is proportional to the Pauli usceptibility and the electron-nuclear (or hyperfine) nteraction in the metal. It is therefore closely linked o the problem of electronic structure and is fairly omplex. Considerable progress seems to have been made already, and in due course the phenomenon hould be a useful source of information to the metal physicist.

C. G. Shull and E. O. Wollan present a superb ccount of the structural information so far obtained om experiments on neutron diffraction. The power f the technique can be seen by contrasting the emarkably detailed information it yields about the mmonium halide transitions (p. 155) with the very artial results obtained from nuclear resonance tudies (Pake's article, p. 81). Other important tructures which have been investigated by neutron iffraction include: ice (Pauling was right), some rro-electrics and liquid helium. Scattering of eutrons by phonons gives what is at present rather rude information about the vibrational spectrum. Results from magnetic scattering by unpaired elecons are numerous and precise; the technique is obviously of special importance to students of magnetism.

The theory of specific heats and lattice vibrations is dealt with in a leisurely and lucid way by J. de Launay. A good deal of this material is well known, but there are some fresh results, including some particularly careful comparisons of theory and experiment.

The longest article in the book (140 pp.) is by F. Seitz and J. S. Koehler on the displacement of atoms during irradiation. The authors can scarcely be blamed if outsiders find that this is the least satisfactory article in the book: the subject is intrinsically of great complexity. It may well be that to those working in the field of irradiation displacements the article will serve as a searchlight, because it concentrates on quantitative arguments even when they turn out to be wrong by a factor of 5 or 10. However, this sort of thing is very demoralizing for non-specialists, and one wonders whether it might not have been better to have published the article elsewhere.

R. O. DAVIES

DESIGN FOR STATISTICIANS

Experimental Design

Theory and Application. By Prof. Walter T. Federer. Pp. xix+544+47. (New York and London: The Macmillan Company, 1955.) 77*s*.

AN author who plans to teach the practice of design and analysis of experiments commits himself to writing more systematically and in greater detail than Fisher, yet at a lower level of mathematical sophistication than Kempthorne. However useful his book for reference purposes, he can scarcely expect it to prove attractive for consecutive reading. Despite these difficulties, Prof. W. T. Federer has produced a book that will be valuable to statisticians and experimenters.

Comparison with Cochran and Cox, whose similarly titled book has established a high standard, is inevitable. Federer includes a greater range of designs, especially in respect of factorial sets of treatments and of types of lattice, and his instructions for analysis of these will be widely used. He is less successful in showing relations between designs, his system of classification tending to emphasize distinctions rather than connexions. Disappointingly, but perhaps not surprisingly in view of the difficulty of the problems, the discussion of change-over and rotation experiments is quite inadequate. The Box–Wilson methods of exploring response surfaces receive only a reference that gives no clue to their nature. The lengthy account of alternative significance tests in Chapter 2 is not particularly relevant to design, and, in view of the incomplete discussion of some interesting categories of design, its inclusion seems an error of emphasis.

Many readers will regret the frequency with which ideas and techniques are left undescribed, with no more than a reference to the original publication in a journal. The impressive list of 340 references is of interest for many unfamiliar items, and remarkable for some of the omissions. In so long a book, however, one might expect to find the argument of important papers digested and summarized; too often, all that appears is a statement of conclusions, or perhaps only the title of an unpublished paper or inaccessible report, and a proper appreciation of even Prof. Federer's own work is impeded in this way.

Teachers of statistics, including even those who do not find it suitable as a manual of instruction, will welcome this book. Not only does the text contain detailed working of many numerical examples, but also at the end is a very fine collection of problems for further study. These are largely concerned with agricultural experimentation—indeed, throughout the book there is a curious uncertainty as to whether the intention is to discuss field experimentation alone or a broader range of experimental situations—but they are excellent material for testing the student's understanding. They are not only exercises in computation but also illustrations of the kind of thought needed for experimental planning, and their value is increased by an additional extensive bibliography. Too often, the designing of experiments is regarded as a Procrustean process of fitting the experimenter's wishes to a standard form; this book rightly encourages recognition of the statistician's responsibility for devising a design that is practicable and efficient in answering the questions that concern the experimenter.

D. J. Finney

AN AGRICULTURAL READER

A Textbook of General Agriculture

By James Gillespie and P. Hathaway. Pp. 367+28 plates. (London: Macdonald and Co. (Publishers), Ltd., 1956.) 30*s*. net.

In England and Wales there are three levels of formal education in agriculture. The universities give three- or four-year degree courses and supply the bulk of the research, advisory and other professional workers, though a fair proportion of agricultural graduates finally become farmers. The agricultural colleges give two- or sometimes three-year diploma courses for those intending to become farmers, farm managers or technicians. The county farm institutes offer one-year courses which cater for the sons of small farmers and farm workers, and for others who need a short, mainly practical, training.

As a husbandry text-book, the university student has, for many years, mainly relied on Watson and Moore's "Agriculture: the Science and Practice of British Farming", while the college student has been faithfully served by Fream's "Elements of Agriculture". Although numerically the farm institutes have the greatest output of students, they have not, until now, had the great advantage of a generally accepted and frequently revised text-book. J. Gillespie and P. Hathaway have gone some way to fill this gap, but their contribution will need a good deal of re-shaping if it is to become a standard text-book with a large enough, and a steady enough, demand to justify revised editions every four or five years.

Unfortunately, the title is misleading; the book is not a comprehensive text-book. On the contrary, it is, as the authors claim, "a series of essays that cover a number of features of scientific farming". As such, the book is simple and, on the whole, clearly written and well illustrated. The subjects of the component essays are well chosen. Their range, however, is too narrow. Whether one regards this publication as a text-book or a reader, it concentrates too much on the biological, that is, on the husbandry side of farming. In these days, the three sides of the farming triangle—husbandry, mechanization and business management—are almost equal in importance, so it is rather disappointing to find that Gillespie and Hathaway completely overlook the business side and rather neglect mechanization, though there is a useful descriptive chapter on farm machinery.

These, however, are points which could be put right in future editions. The important thing is that the authors have had the courage to attempt to fil an awkward gap by producing a readable book for a type of student that is often unwilling to read. In later life these students frequently become smal farmers or, say, herd managers, and we must welcome any book which can help to equip them to cope with the ever-growing complexity of modern farming.

A. N. Duckham

CHEMISTRY OF LIVING CELLS

The Chemistry of Living Cells

(Harper's Chemistry Series.) By Prof. Helen R Downes. Pp. x+549. (New York: Harper and Brothers; London: Hamish Hamilton, Ltd., 1955.) 52*s*. net.

This introductory text-book, by one who has taught biochemistry for many years to senior students who major in chemistry or in one of the biological sciences, has a flavour of a kind which is all too unusual in modern text-books of biochemistry The historical approach has been widely used in the belief that students should be introduced to the outstanding scientists in their field and encouraged to give them "a local habitation and a name", and shor biographies of prominent investigators are included as footnotes. Delightfully appropriate quotations from literature, both scientific and non-scientific introduce many of the different sections.

The text is lucid and extremely readable, and the illustrative diagrams apposite and clear. So far as possible, the subject-matter has been presented in conjunction with specific experimental data. Each chapter concludes with suggestions for furthe reading and a score or so of "Study Questions".

The first part of the book, entitled "Some Preliminary Considerations", includes sections on "Biochemical History and Literature", "Some Selected Properties of Aqueous Solutions" and "The Structur of Living Forms". Part 2 is concerned with th organic constituents of cells—carbohydrates, compounds of nitrogen, lipids and enzymes. The thir part, that dealing with "Intermediary Metabolism" is naturally the largest and takes up about one-hal of the whole book. The processes of metabolism in micro-organisms and in higher plants are, whereve appropriate, compared with those in the anima world.

This scholarly work constitutes an excellent ke to modern biochemistry for those who have failed t keep abreast of a rapidly expanding subject, or wh may be meeting it in its modern form for the firs time. Of the author herself, one might perhaps without disrespect quote the lines from Thomas Hobbes "Leviathan" with which she opens the section o History and Literature, "But this is certain; b how much one man has more experience of thing past than another; by so much also he is mor prudent and his expectations the seldomer fail him' The clarity and accuracy which Prof. Downes ha infused into this book result from much experience wide reading and careful writing.

F. G. Young

CAUSES AND CONSEQUENCES OF SALT CONSUMPTION

By Dr. HANS KAUNITZ

Department of Pathology, Columbia University, New York

THE addition of salt (sodium chloride) to our food has been curiously taken for granted although there seems to be little physiological evidence as to whether or not we are benefited by this habit. Ever since historical records have been kept, salt has played an amazingly important part in the lives of men. Wars have been fought over its sources, and for centuries its trade was more important than that of any other material, as can be seen from the word 'salary'[1,2]. Homer called it "divine", and it has played an important part in many religious cults, in folk-lore and superstitions[3].

Although there was certainly a great deal of deep wisdom connected with the use of salt in ancient rites, it scarcely seems possible at present to appreciate the meaning of the old cults because we have as yet been unable to free ourselves from many prejudices connected with its use. In our own time, the sharpness of the discussions as to the advisability of salting one's food may still be a reflexion of this tradition, which also makes it understandable that the discussions are so frequently carried on by faddists rather than nutritionists.

For these reasons and because the physician is so frequently approached with the question of whether or not one should use salt, an unprejudiced discussion of this subject seemed desirable. It should be stated, however, that undeniable facts, which should form the basis of this discussion, are indeed scarce. One is forced to be guided all too often by biological nnuendoes and vague clinical impressions; thus the conclusions here set forth should be taken with more than a "grain of salt".

It seems particularly timely to give consideration o the problem of the action of sodium and potassium alts from a point of view other than their conventionally accepted role as regulators of osmotic pressure because, in the present era of cell physiology, the onclusion is inescapable that inorganic materials play an important part in hormonal and enzymatic processes. Therefore, it seems not inappropriate to discuss the role of sodium and potassium salts from this point of view, although at this time the coniderations are largely of a speculative character.

Theories which lay the groundwork for our own oncepts were gradually developed about one hundred and fifty years ago. In a book which reveals a remarkably modern outlook, Lehmann[4], in 1853, came to he conclusion that the adding of salt to natural foodstuffs is unnecessary for man. This view seemed to be supported by the fact that most animals, in freedom and in captivity, do well on natural foodtuffs without addition of salt. Although some pecies (for example, cattle, deer, etc.) consume salt agerly when they are offered the substance or when they encounter it in salt licks, there is no proof that they need it for a healthy life.

Later, however, von Bunge[5] formulated his famous hypothesis that extra dietary salt is needed by populations consuming predominantly vegetable products. The excess salt was presumed to be necesary for the more effective excretion of potassium. Bunge arrived at this conclusion on the basis of anthropological studies which he thought indicated that nomadic societies mainly subsisting on meats do not add salt to their food, whereas, once agriculture is developed, salting becomes necessary. He linked this with his observation that the intake of salt is accompanied by the rapid onset of potassium excretion. However, he emphasized that the large amounts of salt usually consumed are out of proportion to what he thought are biological needs. Osborne and Mendel later showed that salt requirements for growth of experimental animals are indeed low; their animals were able to live on traces of salt[6]. Thus, one might have expected that this theory could never have achieved major importance; but, curiously enough, this has not been the case, and it is still cited without further discussion by current text-books of nutrition[7] and anthropology[8].

Objections to the theory should by now be all too obvious. So far as the increased potassium excretion after salt intake is concerned, such a reaction occurs unspecifically with many injuries and diseases[9]. Bunge himself never offered any proof that the increased potassium excretion is biologically of advantage, although he implied so. Now we might be inclined to the opinion that these potassium losses are disadvantageous.

As for Bunge's anthropological data, he brushed away the objection that some African tribes mainly subsisting on a vegetarian diet use potassium-rich plant ashes rather than salt as a condiment[10]. Even at the present time there exist a considerable number of societies which do not add salt to their food. Important in this respect are studies by Kroeber[11] of the food habits of Indians of the north-west Pacific. In the southern half of the area studied salt was used, but not in the northern half. There was no predominance of plant or animal food in either region.

I have been given recent and direct anthropological evidence dealing with this question by various workers in this field*. I have learned of studies of places as distant as Melville Island in Australia, the Kalahari Desert in South Africa, and Tierra del Fuego which lead to the conclusion that the use or non-use of salt by various tribes is irrespective of the amount of agricultural products they consume. The observation is probably of deep significance[12] that the Siriono Indians of eastern Bolivia, a hunting people, were ignorant of salt until it was introduced to them by an anthropologist. At first, they found it distasteful, but they later developed a craving for it. This indicates that once some people are exposed to salt, they cling to its use stubbornly—as do so many of us to the consumption of alcohol, coffee, nicotine, etc.

When carefully weighing the available evidence, one cannot escape the conclusion that normal metabolic processes are possible without the adding of salt to natural foodstuffs. Why then do we eat salt? Merely to answer that certain societies like its taste whereas others do not would be trite and superficial.

---

* I wish to express my gratitude for the invaluable information given to me by Miss Jane C. Goodale, of the University Museum of the University of Pennsylvania, Drs. S. K. Lothrop, Hallam L. Movius, jun., and Mr. John Marshall, of the Peabody Museum of Harvard University, and Dr. Harry Tschopik, jun., of the American Museum of Natural History.

It seems to me that salt intake is probably correlated with emotional stimulation, a fact perhaps more keenly appreciated in the superstitions of the ancients than in our own rational approach. In view of the fact that this stimulation may be consciously or unconsciously pleasurable, it may be a causal factor in the craving for salt.

When we now try to deal with the possible consequences of adding salt to the diet, it must be emphasized that the nutritional essentiality of salt for humans has been firmly established. Only the quantity necessary is much in doubt. For a better understanding of this subject, it seems advisable to review briefly the main trends in studies dealing with the biological effects of sodium chloride.

One involves investigations of its distribution in the organs and the excretion of salt in health and disease. Others deal with the peculiar antagonism of sodium and potassium in living organisms. An important subject of investigation is concerned with why salt is an essential ingredient of any living cell; and another trend centres around the regulatory mechanisms, especially of the higher animals, developed for the maintenance of an optimum distribution in the body.

The high potassium content of the parenchymatous cells as opposed to the higher sodium chloride content of the blood serum has been recognized at least since von Liebig's time[13]. Soon thereafter, many studies were conducted which gradually led to the recognition that, in disease, the low sodium chloride content of the cell increases while the potassium level decreases[14,15]. Speculation as to how the body can maintain the high concentration gradients within the distance of a few microns between the surface of the cell and the blood plasma originally involved the idea of the specific permeability of cell membranes. It was held that the cell membrane is specifically permeable to potassium salts and almost impermeable to sodium chloride under normal conditions and that this is disturbed in disease.

Some investigators recognized the weaknesses of these hypotheses at an early date. Keller, in particular, attacked the idea that the separation of the minerals was due to the function of an 'inert' membrane rather than to the discriminatory power of the whole living cell. He tried to replace this static view with his electrostatic theory, the study of which is still rewarding even after fifty years[16]. Nevertheless, the permeability theory was accepted by most biologists until isotope studies[17–19] proved that the cell membrane is equally permeable to both potassium and sodium salts and that the low sodium chloride content of the cell is due to its rapid expulsion from the cell. This mechanism is now often referred to as the 'sodium pump'[20], a term which might well be improved. Although these studies prove that the removal of sodium chloride from the cell is a dynamic process the disturbance of which leads to the accumulation of sodium chloride within the cell and although many modern physiologists have demonstrated the weaknesses of the membrane theory[21,22], some investigators are not as yet ready to give it up entirely[23].

The modern concept of competitive antagonisms within enzyme systems, which gradually evolved from studies on minerals[24], has proved a useful tool for the understanding of some functions of sodium and potassium salts. In practically all biochemical and pharmacological studies, it has been shown that sodium and potassium have opposite functions. For example, potassium salts favour diuresis; sodium salts do the opposite. Many more examples have been cited[9]. Lately, some evidence has been put forth that this antagonism is particularly important in regard to the action of chloride, the biological effect of which depends upon whether it is accompanied by sodium or potassium[25].

In studies concerned with the question of why sodium chloride is essential for the living cell, tenable ideas are sketchy. It seems important that a number of enzyme systems can only function if sodium chloride is present at certain concentrations[26,27]. In view of the fact that we now believe that the life of the cell is maintained by enzymatic processes, sodium chloride is an integral part of the cell.

These dynamic equilibria are encountered in any living organism. In higher animals they are, to a considerable extent, under hormonal control, and disturbances of the more basic processes become noticeable if the hormonal control breaks down. Thus, one finds that, in many diseases, the sodium–potassium ratio in the tissues is disturbed, which probably interferes with metabolic processes bound to a constant sodium–potassium ratio[28]. It is quite probable that in diseases which are of generalized character and are also accompanied by signs of renal damage, excess dietary salt can enhance the disturbances of the sodium–potassium ratio in the tissues and can thus contribute to the occurrence of metabolic failure[29]; but these conditions are by no means clear, and the influence of dietary salt in health and disease can be better appreciated from its effect on the hormonal mechanisms than from its action on the basic processes.

The regulatory mechanisms of salt metabolism not only involve incretory glands but also every major organ directly or indirectly. One mechanism involving the central nervous system was discovered by Claude Bernard[30], who demonstrated that injury to a certain part of the medulla is followed by the excretion of large amounts of sodium chloride. Although a great deal of thought has been given to the central nervous regulation of mineral metabolism neither its correlation to other regulating mechanisms nor how it is affected by changes in salt intake is clear.

Renal mechanisms in salt metabolism have received considerable attention. In fact, the salty taste of urine attracted the curiosity of people for a long time, and this was the reason for its medicinal use[1] Despite the enormous amount of work done since then on the excretory mechanism of the kidney there is little evidence as to whether the dietary intake of salt eventually interferes with the excretory power. From an evolutionary point of view, it i well to remember that sodium chloride is a scarce material for most animals and is constantly reabsorbed by the kidney. Excess salt intake force the kidney to excrete rather than to reabsorb it which may 'prove too much for it' in the long run. Such a view is supported by the rapid occurrence of histological changes in the kidneys of animals on high dietary salt intake[31].

The regulatory mechanism for sodium chlorid metabolism at present best understood rests in th adrenals. This function of the adrenal cortex wa educed in R. F. Loeb's studies on patients with Addison's disease[32]. It was demonstrated that th low serum sodium chloride values in patients with adrenal insufficiency are associated with continued urinary losses and are accompanied by low potassium excretion and increased serum potassium values. These changes are prevented by the normal secretion of the adrenal cortex involving steroids such as deoxycorticosterone, cortisone and aldosterone. However, these hormones not merely influence sodium chloride and potassium salt metabolism but also play an important part in the regulation of protein metabolism (increased urea excretion in hyperadrenalism), carbohydrate metabolism (diabetes in adrenal hyperfunction; hypoglycæmia in adrenal insufficiency), blood pressure (hypertension in adrenal hyperfunction; low blood pressure in adrenal insufficiency), fat metabolism (changes in fat distribution in adrenal hyperfunction), pigment metabolism (discoloration in adrenal insufficiency). If, then, certain body functions are directly influenced by the adrenal cortical hormones, one might ask whether the intake of sodium chloride affects them because of its intimate relationship with adrenal function.

Abundant proof has been given that the deleterious effects of adrenal insufficiency can be at least partially counteracted by the administration of salt. This is true both for humans suffering from Addison's disease[32] and adrenalectomized animals[33]. On the other hand, salt intake is clinically undesirable in conditions in which the induction of hyperadrenalism is a disadvantage. As is known, the administration of either cortical hormones or salt may lead to similar symptoms in circulatory conditions, hypertension and the like.

There exists by now a considerable body of evidence linking the functions of the cortical hormones to those of salt. Thus, hypertension produced by deoxycorticosterone is enhanced by simultaneous administration of sodium chloride[34]. The kidney lesions[35] and changes in food and water intake brought on by salt are potentiated by cortisone[36]. There exists, furthermore, a considerable similarity in the influence which the adrenal cortex or salt exerts on carbohydrate metabolism. Hyperadrenalism is accompanied by increased deposition of glycogen in the liver and a high blood sugar. On account of the simultaneously increased urea excretion, it was deduced that the increased glycogen formation is due to catabolic processes in protein metabolism[37]. The administration of salt leads to similar changes, namely, increased deposition of glycogen, reduced oxidation of glucose leading to increased blood sugar and increased urea excretion[38]. On the other hand, the reduced intestinal absorption of glucose in adrenalectomized animals can be equally corrected by salt or by adrenal hormones[39,40]. Unless one assumes that this latter finding is only due to improved intestinal blood supply, a more specific salt effect becomes probable, which leads to the conclusion that the effects of salt and of adrenal hormones on carbohydrate metabolism are perhaps interrelated and that the mechanism of this effect is the stimulation of the cortex by salt. The restoration of carbohydrate metabolism in adrenalectomized animals may perhaps be due to the stimulation by salt of tissues which are functionally related to the adrenals. Additional material in support of such a theory will be given below.

Thus, the conclusion is unavoidable that cortical hormones and salt enhance each other's actions. But the question must be asked whether this relationship is important when salt is added to the diet, because one might argue that excess salt leads to a compensatory decrease in adrenal secretion of some of the hormones. This latter seems improbable because it has been shown experimentally that increased salt intake is followed by adrenal enlargement suggestive of adrenal hyperfunction[9]. Clinically, high salt intake is probably related to hypertension[41], again a sign of high cortical hormone secretion.

Such a concept is supported by the effect of sodium chloride in a number of conditions which have in common: loss of sodium chloride by way of one of the body fluids, a drop in serum sodium chloride, and a favourable response to the administration of salt. In addition to Addison's disease, one should mention here heat exhaustion, various uræmic conditions with or without histological signs of kidney disease, and high intestinal obstruction. It is usually believed that the benefit resulting from the intake of sodium chloride in these conditions is owing to the replacement of sodium chloride which has been lost. A more careful analysis indicates a different mechanism.

In profuse sweating, the sodium content of the sweat and urine is rapidly reduced to such an extent that the total salt loss was, within five to eight hours, less than that occurring in the same period without profuse sweating[42,43]; a correlation between the salt content of sweat and adrenal activity has been fairly well established[44,45]. The fact that various uræmic conditions respond favourably to salt administration has been well known for at least thirty years[46,47]. These studies are related to observations on 'salt wasting nephritis'. No balance studies indicate whether these patients actually had a negative salt balance. We were able to carry out such a study on one patient with a rapidly progressing uræmia, profuse vomiting, and a drop in serum sodium chloride. This patient consumed only a little bread and milk and yet had a positive sodium and chloride balance[29]. Similarly, it is known that the amounts of sodium chloride necessary for improving the condition of animals vomiting because of intestinal obstruction are much higher than the amounts actually lost.

The improvement produced by salt in the above conditions cannot be due merely to the replacement of salt losses but must be rooted partly in some pharmacological effect of the substance. The therapeutic effect becomes understandable if one assumes that the pharmacological effect of salt is that of adrenal stimulation, which results in the improvement of the existing 'stress' condition. This theory would be more acceptable if it could be demonstrated that there is some reason for the assumption that a similar mechanism is partly responsible for the salt action in Addison's disease and in adrenalectomized animals. In human adrenal insufficiency, the amount of salt required to produce optimal clinical improvement is high, perhaps 50–100 times what might be considered 'normal' minimum requirements. Whether these high requirements are only due to the high renal losses or whether they are also needed for their adrenal-stimulating effect has not as yet been studied. If the effect were only due to the replacement of losses, one should suspect that the amount just sufficient to bring about equilibrium of the salt balance should allow optimal clinical improvement. Whether the high doses are necessary to give equilibrium of the salt balance or whether this could be achieved with much smaller amounts has not as yet been studied. Some very sketchy information obtained on adrenalectomized rats indicated that the salt requirements for maximal improvement are much higher than those necessary to bring about equilibrium of the balance. This point, however, needs more attention in the future.

Finally, if one asks whether a similar mechanism may also be responsible for the action of salt in adrenalectomized animals, some pertinent data can be uncovered in the literature. As mentioned before, the intestinal absorption of carbohydrate is restored by salt or adrenal hormones[40]. Similarly, fat resorption is improved[48]. Salt or cortical hormones keep hæmoglobin formation at normal levels[49], keep adrenalectomized rats fertile[50], and prevent cytological changes in the pituitary of adrenalectomized animals[51]. Inasmuch as salt has scarcely a hormonal effect *per se*, its action may well be mediated by stimulation of tissues capable of partly replacing the adrenals.

The stimulating effect of salt probably sets in motion adaptive mechanisms involving enlargement of the liver, kidneys and adrenals; this has been found in experimental animals[9]. Similar conditions have been thoroughly discussed in many other 'stress' conditions[52,53].

The possible changes, especially perhaps in the emotional sphere, brought on by the stimulating action of salt are, of course, entirely a matter of speculation. The greater responsiveness of people, if they were so stimulated, could have helped throughout the ages in the accumulation of knowledge. Whether this is one of the roots of the reverence which was accorded salt by the ancients can scarcely be guessed at this time.

It would be of inestimable value if we could be sure how long ago the majority of mankind learned to eat salt. It has been assumed that this took place when peoples went through their neolithic stages, which were accompanied by the introduction of agriculture and which took place for the more complicated civilizations about five to ten thousand years ago. The evidence for the simultaneous introduction of agriculture and salt eating is scant. The first known signs of salt mining were found in the Austrian Tyrol and date back to the late Bronze Age for that part of the world, about 1000 B.C. However, it is obvious that all the more complicated older cultures (Egyptian, Babylonian, Chinese) antedating that period knew the use of salt. One clue as to when tribes became used to salt is that Sanskrit and its daughter languages have no common root for salt and that therefore the Indo-Europeans, when first migrating, did not then know its use[1]. For these reasons, we are still inclined to believe that salt was gradually more extensively used when the tribes went through their neolithic stage.

Is there any reason to assume that the constant use of salt as a stimulant has changed our intellectual capacity? If our previous speculations are correct, one must assume that man in the Upper Palæolithic Period (ten to thirty-five thousand years ago) did not salt his food; yet, Cro-Magnon Man created magnificent art. Intellectually, therefore, he was our equal. He differed from us only in his lack of knowledge. Thus, although salt-eating did not change man intellectually but may have facilitated learning, it possibly was an important historical force.

Are there, finally, any reasons why the physician and public health worker should recommend a certain level of salt intake on the basis of present-day scientific knowledge? There is no question that there is a sound basis for the prescribing of low-salt diets in many diseases, particularly those involving the circulatory system. When it comes to normal people, however, recommendations are infinitely more difficult. It is certainly true that the chemistry of the body does not require the addition of salt to our food. The physician, however, is not primarily interested in the mere metabolic processes but in the general welfare of his patients, and he should consider that the quickened pace of a more complicated society demands persons with a heightened responsiveness. Salt may be one of the ingredients producing this effect.

PERSONNEL MANAGEMENT

THE struggle for productivity in industry can never be won. Each success leads to a lifting of the sights and a new target is revealed. In each succeeding situation differing relations between various groups of employees—and particularly between management and men—are developed and, unless handled with wisdom and care, lead to clashes in which productivity becomes either static or declines. The importance of good human relations is now recognized to be essential if British industry is to develop, and it is not surprising that the Institute of Personnel Management continues to grow in prestige and authority.

This was reflected in its annual conference which, at Harrogate during October 12–14, attracted almost a thousand people representing all levels of management from industry and commerce, government departments, the armed services and various agencies at home and overseas.

The theme of the Conference was full employment and industrial change and, in the opening address, Dr. Alfred Torrie discussed the limitations of the contribution which social science could make to management. Quoting from experience in the services and elsewhere, Dr. Torrie showed how even senior members of government—as well as many others—are resistant to change and unwilling to try anything new which might involve the emotions. Social scientists, too, find it difficult to get their ideas accepted; they are apt to be remote and impersonal, to be objective about human emotions. The social scientist is keen on studying the group and making the group a more important factor than the individual. But the lesson of history is that the most significant advances in the fields of science and invention came as a result of the lonely searching of individuals. The social scientist is so anxious to find out what adjustments can be made to the norm that he forgets that it is the individual, the unusual, the innovator, the inventor that is the carrier of new ideas. The social scientist wishes to measure and control and treat people statistically; but tough-minded people, the tough-minded individuals, resist such treatment.

The third limitation of social science is that it does not account for the whole of the human being. There are far too many variables present. One variable, which is an external one, is that theories may be formed, research may be done, a theory may be validated and its application to industry proved; but unless some sort of social action occurs, it becomes sterile and void. The social scientist is limited in believing in a man-centred world. Spiritual man may be dismissed; but the spiritual factor is always there, sustaining and inspiring and motivating man's behaviour, giving meaning and purpose to life. Social scientists contest all false judgments; but love, humility, honour, loyalty, justice and mercy, and the ways by which men respond to each other in a social situation cannot be measured.

All great people are unstable, and so they have to be. They are maladjusted to the norm and they are unstable because of the strength of the inspiration, the strength of the ideas within them that they are striving to express, to which they are striving to give birth. If the social selection sieve gets finer and finer, innovators are going to be thrown out and society will be deprived of new ideas in the future. Social science is necessary for understanding, but so is spiritual awareness.

How to integrate social with technological change was examined by Lord Halsbury in a most brilliant and penetrating address. He made it abundantly clear, for example, that advancing technology has nothing to do with employment or unemployment; the latter is an economic phenomenon and is controlled by economic policy. Over the past fifty years productivity has been rising at about 1½ per cent per annum, and, since the war, that rise has increased to 3 per cent per annum. Full employment in 1956 is due not only to advances in technology but also, in a post-Keynesian era, to a high investment rate.

There was also a change in the pattern of skill between 1900 and 1956. Skill is subject to two processes operating in reverse directions. Skill is always being degraded into semi-skill; semi-skill is always being degraded into unskill; and, at the same time, unskill is always being upgraded into semi-skill, and semi-skill to new skills. These can be written as two processes operating in reverse directions, and from society's point of view, is the overall direction of the balance, by way of change, and, from the individual's point of view, how it affects him on the short-term view.

In addition to these transformations of skills, which are continually under way, there is a disappearance of old trades rather than old skills, and an appearance of new trades rather than new skills, and the overall effect, if treated statistically, is an overall increase in skill in the community at the highly skilled end, and the demand for a higher standard of education among the so-called unskilled at the other end of the range. It is a great pity that there is no flow diagram of the human career in better statistical form than is available to us at the present time.

What are the events when a man is displaced by a machine? If the craft is a dying craft, it generally turns out that it is represented by an ageing population. The dying population and the dying craft emerge hand in hand, and as the trade dies, so the recruitment of youths for apprenticeship to it begins to fall off, and there seems to be no great difficulty in matching the one process to the other.

When men are displaced by machines the problem is to minimize the stresses arising out of the various strains, and this leads to the need for retraining the industrially displaced person. The issue here is not how successful the result will be, but how just the attempt will be. It seems just, if a man is displaced by other men—and these include the whole complex of managers, engineers, drawing office engineers and scientists and so on who are responsible for initiating changes in factories—that the man displaced should be the first to be allowed to work the new process, or for him to be restored to full earning power by being retrained. The cost of retraining should be borne by the parties responsible for the displacement as part of the true cost of the new installation.

In the closing address, the Minister of Labour, Mr. Iain Macleod, suggested that if thinking and planning for change are to be effective and if change is to be accepted without great social disturbances, certain assumptions are necessary. First, that our technologists will be able to continue to devise machines at the present rate of development, and perhaps, at an accelerated rate; secondly, that the capital will be available and that the machine tool industry will be capable of producing them; that the people of the world will be able to produce and to exchange the raw materials required for these machines, and by these machines. Thirdly, that there is going to be a demand for the products of these machines, and that the spending power to acquire them will be available. Fourthly, that good relations between workers and management are achieved—relations of such harmony that vast industrial disturbances become entirely old-fashioned. Lastly, that the benefits of this new age will spread throughout the world.

First, however, man must adapt his industrial customs and his outlook to what many people call the new machine age. Secondly, the use to which man will put the rewards of these technological changes must be considered.

The problem of the redeployment of the labour force is the widespread conviction that, unless something is done, the social and the economic cost of industrial change is going to fall upon the individual worker.

What is needed is a new recognition of social responsibility in industry at the level of the individual firm and the application of that responsibility over a long period. The real responsibility for planning must lie at the level of the individual firm. Employers must now accept the moral responsibility for planning the employment of their work-people exactly in the same way as they accept the management responsibility for planning the building of their factories, the installation of machinery as well as development of their markets.

This is not just a matter of paying monetary compensation; it involves a much deeper change of attitudes, and of habits, which can only come about if everyone in industry is ready to face the full significance of technological change.

Industry can also make a contribution to the problem of adapting society to technological change, and that is in the field of training. The main responsibility of training in industry is industry's itself. If industry paid more attention than it does to the establishment of effective schemes of training for new entrants, it would not only save money for itself but it would also make a most valuable contribution to the flexibility and the increased mobility of the labour force that is so essential to the British economy.

For many years there has been a trend towards the breaking down of processes and, therefore, the training of workers on one operation only. There may be a reversal of that process, a tendency towards synthesis and a training of workers to understand any one in a whole chain of operations; if this is so, it will make greater demands on the capacity of workers, and training for new kinds of work will require a new approach.

What about the rewards from technological change? The expectation is that the new era of production will make possible a higher standard of living. It should remove some of the drudgery and the physical exertion that is still existent in industry. It may be that it will bring more leisure, which in itself will bring a problem with it. If leisure is wrongly used it is bound to lead to boredom and to discontent which will sap and rot our civilization.

Other features of the Conference were a series of one-day courses dealing with the training of operatives, industrial pension schemes, selection methods, and the part of work-study in retail staff management. There were also a number of sectional meetings where delegates were given opportunity to consider details of recent developments in the training of managers, to discuss the case for and against the payment by results, to examine new suggestions which could be used as bases for pay differentials, to explore communications within the work force, and to learn of recent developments in the mechanization of office work.

T. H. HAWKINS

PHYSICAL CHEMISTRY OF PROCESSES AT HIGH PRESSURES

A TWO-DAY discussion meeting of the Faraday Society on the general theme of "The Physical Chemistry of Processes at High Pressures" was held in the Chemistry Department of the University of Glasgow during September 20–21. Some 162 British and 58 overseas scientists attended the meeting, and a lively and well-sustained discussion resulted. Many of those present had the opportunity of enjoying a display of Scottish dances and Scottish songs, through the kind hospitality of Imperial Chemical Industries, Ltd.

This was the first Faraday discussion with this general theme; it is evident that for condensed states of matter, the pressure variable has been much less fully explored than the temperature variable. However, high-pressure techniques are becoming easier to develop and to apply, at any rate up to about 5,000 atm. Increased accessibility of operations at high pressures has resulted in a broadening of the range of physico-chemical measurements becoming available for interpretation. For still higher static pressures, equipment is at present too specialized and costly to favour its widespread dissemination in many laboratories; but results important for the thermodynamics of condensed phases are being obtained in a few centres. The use of transient high pressures up to 10^5 atmospheres or more, as developed in shock and detonation waves in solids, was first applied to the measurement of thermodynamic parameters during the Second World War. Increased attention is being paid to the development of such techniques at the present time, though there are still serious difficulties of interpretation, particularly in systems containing a mixture of solids.

Industrial interest in high pressures has received obvious stimulus from the highly successful polymerization of ethylene and the suggestive results in the polymerization of acetylene, and adds to the significance and timeliness of the recent discussion.

The papers presented and the discussion make it clear that systematic theory has not wholly kept pace with present experimental developments, though some of the contributions at this meeting clarified important theoretical problems. The influence of repulsive forces in practically all high-pressure phenomena is widespread. A useful survey by Dr. T. Cottrell (I.C.I., Ltd., Nobel Division) brought out the difficulties in finding high-pressure parameters that are at the same time simple to calculate theoretically and experimentally sensitive to repulsive force-fields. Various contributors discussed the form and characteristics of repulsion potentials. For close molecular overlap a simple inverse power function of molecular separations fails to represent repulsions successfully; an exponential function may be more hopeful, though a composite function with more than one adjustable parameter seems to be required if the range of repulsion potentials under discussion is at all large. The anisotropy of repulsive force fields for non-spherical systems, and additional complications where repulsions arise in a many-body problem, present other obstacles to theoretical progress. From the discussion it was evident that some of the difficulties are only just beginning to emerge clearly. One promise of theoretical advances stems from the much greater diversity of experimental phenomena, where measurements are becoming available from which repulsive force-fields might in principle be calculated. This was illustrated by many of the experimental contributions to this discussion, and permits a greater degree of selection in applying theoretical considerations.

Another broad group of theoretical problems arises from the interpretation of the transport properties of dense gases; these are of very considerable practical as well as theoretical interest. The outcome of many statistical-mechanical calculations which can be formulated with some mathematical rigour is much too complicated to be applied conveniently to experimental examples. For this reason the devising and testing of simpler models which permit some theoretical insight into transport processes in dense gases offers special opportunities for progress at the present time. In this direction, significant contributions to the discussion by Prof. H. C. Longuet-Higgins and J. P. Valleau (Cambridge), and by Dr. E. Whalley (National Research Council, Ottawa) were discussed by a number of contributors.

A third type of theoretical calculation at high pressures refers to properties of compressed gases, the variation of which with pressure can be attributed to attractive forces. Measurement of such properties as a function of pressure, and particularly a combination of several types of measurements, promises to give rewarding information about details of intermolecular attractions which it would be difficult to obtain in any other way. For example, a contribution by Dr. J. A. Pople and Dr. R. A. Buckingham (Cambridge) indicates useful properties the dependence of which on pressure, though not extensively studied hitherto, should yield new information about molecular force-fields.

Though advances in techniques of working at high pressures were not specifically included in this discussion, the increasing range of phenomena which can now be studied conveniently was illustrated by experimental studies such as those on the effects of pressure on the infra-red and electronic resonance spectra of gases, by Dr. B. Vodar and his colleagues (Laboratoire de Haut Pressions, Bellevue). These promise to contribute novel features in our general knowledge of molecular force-fields. A. M. Benson and Prof. H. G. Drickamer (Illinois) made the interesting suggestion that the pressure coefficient of a vibrational frequency could be employed systematically to supplement the actual numerical value of the frequency itself, in correlating spectral energy-levels with modes of vibration and thus with molecular structure.

The meeting also considered various aspects of chemical reactivity at high pressures. It is usual to separate the influence of pressure on the structure of the solvent, from its influence on various activation complexes involved in specific chemical reactions. From observed changes in the dielectric constant of methanol, discussed by Dr. S. D. Hamann and W. Strauss (Sydney), there appears to be a striking influence of pressure on the structure of this solvent. Presumably this is connected with the open network structure of hydrogen bonds in liquid methanol. It would be interesting and important to know if such an influence of pressure on structure is observed generally in the case of hydrogen-bonded solvents. There was considerable discussion about the interesting changes in the properties of such solvents as they approach and traverse their critical points. For example, in water near and above its critical temperature, it may happen that some of the 'anomalous' properties associated with clusters of molecules of H_2O with the tetrahedral ice arrangement are related in a sensitive way to the extension of such clusters in space.

So far as the activation complexes are concerned, relatively simple concepts, as discussed by various contributors, at present suffice to account for much of the observed influence of pressure on the free energy of activation. The influence of pressure on reaction-rate is quite striking for certain fairly complex molecules, as in cases reported by Dr. S. D. Hamann and D. R. Toplitzky (Sydney), where a five-hundred-fold increase in rate accompanies the increase in pressure up to 15,000 atm. On the other hand, expectations that the steric hindrance in specific reaction mechanisms might be reduced or even eliminated as a result of bond deformation at high pressures proved not to be fulfilled, at any rate in the examples presented at this discussion by K. E. Weale (Imperial College, London). Other striking influences of increases of pressure arise in polymerization reactions. For example, in the polymerization of styrene, rates of propagation and of chain termination have been shown to depend in a marked way on the degree of compression of the solvent. In consequence the mean molecular weight is affected by pressure. Rather less seems to be known at present about how far chain-branching for a given size of macro-molecule is affected by the pressure at which it has been formed. In the polymerization of ethylene discussed by various contributors, the reaction-rate likewise depends in a complex way on the pressure, owing to the various ways in which nearest neighbours influence chain-reactions as molecular packing becomes closer.

A group of investigations on physicochemical processes in detonation and shock waves was presented for discussion by various contributors. The systems studied differed widely in complexity. It seems clear that in heterogeneous polycrystalline mixtures, a complex diversity of phenomena can occur which is by no means fully elucidated. This applies, for example, to studies reported by Dr. L. Deffet and Boucart (Tir National, Brussels), by Dempster, and by Dr. W. Taylor (I.C.I., Ltd., Nobel Division). The mixtures of explosive substances they described can only be termed 'solid' by convention; phenomena such as grain erosion in the detonation reaction-zone are of dominant importance and depend on the intercrystalline free space in a complex way. Much stimulating discussion was held about the physical chemistry of the reaction zone in detonations. The importance of the intercrystalline free space is further emphasized by a contribution which described the behaviour of single crystals studied individually. High initial pressures are found to have only a slight effect on the 'runaway temperature' in the self-heating of single crystals of explosives.

Experiments on the homogeneous detonation of acetylene should in principle be simpler to interpret than the behaviour of heterogeneous systems. However, the formation of solid products of detonation leads to complications when attempting theoretical interpretations. It is not clear at what stage the 'carbon' ultimately obtained from the detonation of acetylene is actually formed; it seems unlikely, furthermore, that the crystal structure and heat content of such 'carbon' can be taken as the same as in ideal graphite. The kinetics of pyrolysis of acetylene in shock waves to give carbon offers further information about reactions at transient high pressures, which present complications due to the formation of solid products of variable physical structure and chemical composition. Extensions of such kinetic studies promise to cover ranges of high pressure and high temperature not conveniently obtainable in other ways. The possibility of obtaining conveniently kinetic results at several hundred thousand atmospheres obviously attracts a number of research groups. However, as in other studies of transient phenomena, relaxation effects may complicate any interpretation of the results on the basis of the thermodynamics of high pressures. Detonation and shock velocities can now be measured with very considerable precision. The measurement of detonation and shock pressures still present technical difficulties, though they may become accessible from techniques such as X-ray shadowgraphy and measurements of mass flow. But in the case of detonations and shock waves there are very serious doubts about the applicability of 'temperature' at all as a significant modulus in describing the statistical distribution of various kinds of internal energy among the molecular and atomic species present. Active research in the physical chemistry of matter at high pressures receives still further stimulus from the possibility of observing transitions from insulator to conductor behaviour of various crystals when sufficiently compressed. Preliminary studies of this kind were described at the meeting and added further zest to a very lively two-day discussion.

A. R. UBBELOHDE

OBITUARIES

Prof. J. C. Cruickshank

JOHN CECIL CRUICKSHANK, professor of bacteriology as applied to hygiene in the University of London at the London School of Hygiene and Tropical Medicine, died on October 30 at the age of fifty-seven. Educated at George Watson's College in Edinburgh, he served in the Gordon Highlanders at the end of the First World War, and then proceeded to the University of Edinburgh, whence he graduated M.B., Ch.B. in 1921. He took the D.T.M. at Liverpool in 1923, winning the Alan H. Milne Memorial Medal, and then served in the West African Medical Service in the Gambia for seven years, gaining tropical experience which was of great value to him and to his students later in London.

Cruickshank came to the London School of Hygiene and Tropical Medicine to take the diploma in bacteriology in 1933, and remained there first as demonstrator, then as lecturer in bacteriology. During the Second World War he directed Emergency Public Health Laboratory Services laboratories, first at Horsham, later at Exeter, returning to the School in 1945 as reader in bacteriology as applied to hygiene, to re-open the Department under the part-time direction of Prof. G. S. Wilson, and to start teaching courses again. Cruickshank was a great teacher, whose wide experience of tropical and public health bacteriology fitted him uniquely well to teach in courses for the diploma in bacteriology, the diploma in public health and the diploma in tropical medicine and hygiene. Many hundreds of students will remember his excellent teaching with gratitude. In 1947 he became professor in bacteriology as applied to hygiene.

Throughout the past twenty-five years, Cruickshank had maintained a steady output of research on bacteriological topics, chiefly on brucella infections and on immunity. He acted for some years as expert adviser to the Public Health Laboratory Service on clostridia and on brucella. He served on the Water Pollution Research Board of the Department of Scientific and Industrial Research and its Detergents Committee, and on various other public committees and bodies. He was a member of the Pathological Society, the Society of General Microbiology, and the Medical Research Club. In 1952 he gained his M.D. (Edinburgh) with a gold medal. He was loved and respected by all his colleagues and students and all others who knew him; his early death is a great blow to the School. He leaves a widow, two sons and a daughter.

E. T. C. SPOONER

Dr. John McLuckie

DR. JOHN MCLUCKIE, until recently reader in botany in the University of Sydney, died on September 27 at the age of sixty-six. He was still in harness, for he was asked to come back after his official retirement to take the advanced mycology course. He had given a lecture and a practical class on the day of his death.

McLuckie was born in Killermont, in Dunbartonshire, on August 12, 1890. He was the eldest of a family of seven. His father was a gamekeeper, and as a boy John McLuckie learnt to handle a fishing rod and a gun—skills which he practised with great distinction during his forty years in Australia. From these early days he acquired, too, an intimate knowledge of natural history and a love for the countryside.

He won a bursary to the school which is now Bearsden Academy and proceeded in 1909 to the University of Glasgow, where he was a pupil of F. O. Bower. After graduation in 1914, McLuckie sailed for Australia to serve under Prof. A. A. Lawson (also one of Bower's pupils) in the newly established Botany Department in the University of Sydney.

He devoted his whole career to this Department. His early work was a series of studies in mycorrhiza and parasitism, published in the *Proceedings of the Linnean Society of New South Wales*. Then he turned to ecology; his primary surveys of the Kosciusko and Mount Wilson districts are still standard works, and show how well McLuckie had mastered (with the aid only of an out-of-date handbook of the flora) the perplexities of Australian vegetation. But it is as a teacher that he will be remembered. For forty years medical students, pharmacists, scientists and agriculturists passed through his classes. Some of them arrived under the impression that botany was a 'soft option', but none who survived McLuckie's practical classes preserved that illusion. He took immense pains to ensure that students were given good plant material for their practical work (it was not unusual for first-year students to see fertilization in living *Hormosira*); and having provided good material, he took immense pains to ensure that students observed thoroughly and drew accurately. He was exacting in his demands and he had no patience with a student who did not take botany seriously; but the student who did take botany seriously found in McLuckie an enthusiast who delighted in plants and for whom no trouble was too much. He conveyed to his colleagues an impression of deep loyalty to his subject. On field trips he was at his best, and his students will long remember him striding ahead, under the scorching Australian sun, to show them some rare plant or some characteristic patch of vegetation; and then standing by, lighting his pipe and smilingly awaiting their comment.

Through many changes of staff, and during dislocations caused by the War, the Botany Department depended for its stability and cohesion on McLuckie. On at least five occasions he modestly undertook the duties of acting professor. He was a dedicated teacher, and his massive "Australian and New Zealand Botany", published jointly with H. S. McKee in 1954, is a fitting memorial to his career.

ERIC ASHBY

NEWS and VIEWS

Nobel Prize in Physics for 1956: Dr. W. Shockley, Prof. J. Bardeen and Dr. W. H. Brattain

THE Nobel Prize in Physics for 1956 has been awarded, jointly, to Dr. W. Shockley, Prof. J. Bardeen and Dr. W. H. Brattain for their work on emiconductors. During the years they worked ogether at the Bell Telephone Laboratories they emoved many of the obscurities and much of the mpiricism from semiconductors and founded the ubject of transistors.

Bardeen and Brattain discovered transistor action when they placed two metallic whisker tips on the surface of one small piece of germanium and found that the current passed by one metal-semiconductor contact greatly influenced the properties of the other, f the separation was less than about 0·02 cm. Both current and power gains were demonstrated in this, the first solid-state amplifier (now called a point-ontact transistor). The existing, one-carrier, theories f conduction postulated that the majority of mobile harge-carriers in extrinsic semiconductors were ther negative electrons in the conduction band *n*-type conductivity) or vacancies (holes) in the alence band behaving as positive charges (*p*-type onductivity). Because transistor action could not be explained in terms of majority carriers only, Bardeen and Brattain proposed that minority carriers -injected at the first contact, transmitted through he semiconductor in the presence of the majority arriers without much probability of mutual (hole-ectron) annihilation and collected at the second ontact—were responsible.

Shockley saw that metal contacts were not essential o the action, and in 1949 he analysed the properties f *p–n* junctions within one piece of a semiconductor nd predicted the behaviour of transistors having *-p–n* and *p–n–p* structures. He very quickly btained full experimental confirmation. A theory f the recombination of electrons and holes was roposed and direct measurements made of many roperties of minority carriers. Later he proposed nd analysed another structure—the unipolar transistor—which, though using *p–n* junctions, is ependent for power gain on majority carriers only; again, experiments quantitatively confirmed his predictions. Bardeen and Brattain had meanwhile returned to studies of surfaces of semiconductors; by careful measurements they added to the understanding of the properties of very thin adsorbed layers in the presence of electric fields. Dr. Shockley is now with Beckman Instruments and Prof. Bardeen is at the University of Illinois.

Control Mechanisms and Electronics at the National Physical Laboratory: Dr. A. M. Uttley

THE appointment is announced of Dr. A. M. Uttley as superintendent of the Control Mechanisms and Electronics Division of the National Physical Laboratory, Teddington, in succession to Mr. R. H. Tizard, who has taken up a post at the London School of Economics. The Control Mechanisms and Electronics Division was formed in 1954 to study the automatic control of experimental, industrial and administrative operations and the development of techniques and equipment for data processing and computation. Dr. Uttley graduated at King's College, London, in mathematics and psychology. After some teaching experience he joined, in 1940, the Telecommunications Research Establishment (now known as the Radar Research Establishment), Malvern, Ministry of Supply, where he remained until his present appointment. During the War he was responsible for the design of many of the synthetic trainers used to great effect in the training of operational crews. While thus engaged, Dr. Uttley developed a keen interest in electronic and in electro-mechanical control systems, developing the split-field type of motor for use in such applications. One of the developments was the now well-known servo-motor known as the 'Velodyne'. Dr. Uttley's immediate interest after the War was in the automatic guiding of astronomical telescopes, and he acted as adviser on electronics for the Sir Isaac Newton telescope. Later, he turned his attention to problems of digital computation and was largely responsible for the functional design of TREAC, an electronic digital computer in use in the Physics Department at the Radar Research

Establishment. More recently he has been investigating problems of control involving a human operator, and of visual pattern recognition. He has examined also problems of muscle control and has studied principles and design of systems which 'learn from experience', with a view to their application to process control. It is anticipated that Dr. Uttley will take up his appointment early in the new year.

Commonwealth Mycological Institute :
Dr. S. P. Wiltshire

DR. S. P. WILTSHIRE, who has recently retired from his post as director of the Commonwealth Mycological Institute, entered as mycologist and assistant to the director (Sir Edwin Butler) in 1922. In 1933 he was appointed assistant director and editor, and director and editor in 1940. His quiet and self-effacing manner tends to hide a tenacity of purpose which has been invaluable to the Institute and of great worth to mycology in general. Thus he contrived the regular appearance of the *Review of Applied Mycology*, the initiation of a series of mycological papers and monographs, a series of distribution maps of plant diseases and a *Review of Medical and Veterinary Mycology* during what has been probably the most difficult period for publication ever known. In addition, he planned and supervised the general organization of the excellent new building which was opened last year.

Dr. J. C. F. Hopkins

DR. J. C. F. HOPKINS, who succeeds Dr. Wiltshire, is known mainly for his work on the diseases of tropical plants, first in Uganda, and then as chief botanist and plant pathologist to Southern Rhodesia. He recently published a book on "Tobacco Diseases". On his retirement from overseas in 1953 he was appointed assistant editor at the Institute. As so much of the work there is concerned with the diseases of crop plants of tropical regions, Dr. Hopkins's previous practical experience will stand him, and the Institute, in good stead.

E. F. F. Chladni (1756–1827)

A GREAT pioneer in the science of acoustics, Ernst Florens Friedrich Chladni was born of Bohemian parents at Wittenberg two hundred years ago on November 30, 1756. He graduated Dr. Jur. at Leipzig in 1782; but on the death of his father abandoned law for natural science, being particularly interested in sound and in music and being inspired by the work of Leonhard Euler and of Daniel Bernoulli. He studied the torsional vibrations of a pendulum and the longitudinal vibrations of strings and rods, and applied the latter to the determination of the velocity of sound in solids. He also measured the velocity of sound in media other than air by filling an organ pipe with the medium and taking the pitch of the note produced. Using brass plates clamped at the centre and excited by bowing at one end, and sprinkling sand on the vibrating plates, he obtained 'Chladni's figures', which he exhibited to the French Institute in 1809. Napoleon was so impressed by this demonstration that he gave Chladni 6,000 francs to enable him to have his book, "Die Akustik" (Leipzig, 1802), translated into French. Chladni never held an official position, and he earned his living by travelling in Germany, France, Italy, Holland, Denmark and Russia, where he delivered scientific lectures and gave recitals on an instrument which he had designed and constructed and which he called a euphonium. He wrote numerous papers and treatises, including several on meteorites. He died at Breslau on April 3, 1827, leaving his money to the poor of his native town and his meteorites to the royal collection at Berlin.

New Research Laboratories of Thorium, Ltd.

MR. G. H. BEEBY, chairman of Imperial Chemical Industries, Ltd. (Salt Division), and also of Thorium, Ltd., opened the expanded Research Laboratories of Thorium, Ltd., at Ilford on November 14. Thorium Ltd., specializes in the production of thorium and lanthanon chemicals and in the manufacture of polishing powders for glass and metal. Thorium metal is used mainly in special alloys for aircraft construction. Thorium oxide is used in some types of optical glass, as a refractory and in making incandescent mantles for pressure lanterns, etc. As thorium is a fertile element several times more abundant than natural uranium, it has a potential application in atomic energy production. The lanthanons are difficult to separate, so most of the commercially used materials are therefore mixtures freed from non-lanthanon impurities. The most widely used mixture contains about 50 per cent cerium and is called 'technical cerium'. This is used for making lighter flints, in the metallurgical field for improving the quality of many ferrous alloys and in making special alloys and for improving the luminosity of carbon arc lamps. It also has uses in the chemical and paint industries and is an importan component of the glasses used in welder's goggles Cerium oxide is an excellent polishing material fo glass and metal; materials containing 50–95 pe cent cerium are used to make the polishing powde sold as 'Cerirouge'. 'Didymium' oxide, a mixture o praseodymium and neodymium oxides, is used to produce colours in glass, and pure neodymium oxide is used to give a spectacular red-blue colour to certain decorative glassware. Lanthanum oxide i also used in glass-making to produce special optical glasses. Samarium is used in making phosphors fo fluorescent lamps. The research department o Thorium, Ltd., has a staff of about twenty, the research manager being Mr. R. J. Callow. Research is conducted mainly into methods of purifying and separating the materials produced by the firm, into methods for process control and into the properties of polishing powders. The new laboratories have a floor area of about 7,500 sq. ft., divided into fiv main laboratories of varying sizes, a pilot-plan room and ancillary space such as library, dark room etc. At the opening ceremony, a number of items of work were shown.

New Training School for Apprentices

A NEW craft training school for apprentices employed by British Oxygen Engineering, Ltd., was opened at Angel Road, Edmonton, on November 15 by Mr. Robert Carr, Parliamentary Secretary to the Ministry of Labour. Since 1951, when the Company new apprenticeship schemes were first put into operation, it was felt that there was a great need for training school to be completely separate from the production workshops. It would provide apprentices embarking on a five-year course with the firm with real knowledge and appreciation of basic engineerin craft skills, and would enable them to assimilate more quickly the training they received in the productio workshops and technical offices, so that they could carry out their jobs with maximum efficiency. Th school will also be used for advanced craft training and also for third-year apprentices to ensure that experience gained in the previous two years in the workshops is firmly established in the minds of the apprentices, that misconceptions can be rectified and new developments taught. The school, which provides for forty-five to fifty students, comprises a machine-shop, fitting sections and a lecture room, and the shops are laid out to enable a wide range of work in plant, industrial, medical and aircraft fields to be covered. It can also be used for intensive courses for the up-grading of fitters, machinists and inspectors, and also for the teaching of new techniques to staff in general. The Company works in close association with the West Ham College of Technology, South West Essex Technical College, Enfield Technical College, Harlow Technical College and the University of London in the provision of sandwich courses.

Electrical Energy

THE first issue of a new monthly electrical journal, *Electrical Energy*, appeared in September. This publication is, in some respects, a companion journal to *Electronic Engineering*, as it is published by the same organization and has common editorship (London: Morgan Brothers (Publishers), Ltd. 3*s*.). It is stated in the foreword to the first issue that it is designed for the professional engineer engaged in research, development, design and manufacture. The articles in the first number cover a fairly wide range of subjects; one deals with the solution of electric field problems using a digital computer, another with modern methods of excitation control for large synchronous machines, and a third describes the principles of operation of the magnetic amplifier. The standard of these articles is pitched at a level which should satisfy a reader possessing a good scientific background. There are, in addition, short articles and notes dealing with items of current interest concerning industrial developments and new electrical equipment, and, finally, a group of book reviews. The journal is well produced and attractive. It is, perhaps, rather remarkable that there should have existed, to-day, a gap in the coverage of the general field of electrical engineering which a new journal could be designed to fill. There was, however, a need for a periodical which would deal with electrical power in all its aspects and would provide especially for more detailed theoretical treatments of technological topics than are, nowadays, appropriate to the old-established weekly journals which serve the electrical industry so well. The declared policy of *Electrical Energy* and the quality of its early issues suggest that it will meet this need, and on that ground alone it should be heartily welcome.

Physics in Medicine and Biology

THE first issue of *Physics in Medicine and Biology*, a new quarterly journal in the same format as the *Philosophical Magazine*, is dated for July (edited by Prof. J. E. Roberts. London: Taylor and Francis, Ltd. £3 10*s*. a year). The journal, which is the official publication of the Hospital Physicists Association, is intended for papers on topics in the borderline fields between physics and the biological and medical ciences, which cannot easily be classified for existing periodicals. It will publish original papers and review articles on studies of the physical properties of living matter, and on the applications of physics and physical techniques to problems in medicine, biology and physiology. In addition, it will publish instrument notes, book reviews, letters to the Editor, and notes on work in progress. An important feature, which will take 20–25 per cent of the space in each issue, is the Abstracts Section under the editorship of W. A. Langmead. These abstracts are taken from a very wide range of journals; in the first issue 130 journals were abstracted. The subtitles of the Abstracts Section give a good indication of the scope of the whole journal: radiobiology, radiotherapy, radiodiagnosis, radioisotopes (biological and clinical aspects), radioisotopes (physical and clinical aspects), radiation dosimetry, physiology, general physics and instrumentation. The first issue contains a review of recent advances in electrophoretic separation methods, and papers on dosimeter calibrations, microspectrophotometry, a profile counter, and α-track autoradiography. The instrumental note is concerned with the specifications of nucleonic instruments which have clinical applications. Although with such a very wide field only a limited number of papers will be of interest to any one worker, it seems probable that, if the high standard of the first issue is maintained, the journal will be well received by many of the growing number of workers interested in that field.

Priestley in the United States

THE home of Joseph Priestley has been acquired and is being restored to its original appearance by the Borough of Northumberland, Pennsylvania, U.S.A. This house, started in 1795 and completed in 1797, and owned for many years by the Priestley family, was purchased in 1920 by the Pennsylvania State University and presented this year (1956) to Northumberland. The home is of Georgian architecture, is in fine condition, and occupies an acre of landscaped ground near the Susquehanna River. Under the direction of the Priestley Memorial Association, the widow's walk, kitchen and laboratory are being restored to their original appearance and the rooms refurnished with American furniture of about 1800. The Association desires to gather all obtainable information on Priestley and on his American home. It would like to receive reprints of articles bearing on his work, and it welcomes correspondence with anyone interested in this matter; visitors are welcome. Correspondents should write to Mr. Lewis K. Rich, 464 Front Street, Northumberland, Pennsylvania.

The Division of History of Chemistry of the American Chemical Society is co-operating with the Priestley Memorial Association in the restoration of Priestley's laboratory. To this end a committee including Sidney Edelstein, Claude K. Deischer and Wyndham Miles (chairman) has been constituted. The committee wishes to locate apparatus of Priestley's American period, with the view of acquiring them or having replicas made. It welcomes correspondence with anyone knowing the whereabouts of apparatus, and with scholars interested in this project; correspondence should be addressed to Dr. Wyndham Miles, Edgewood, Maryland.

Science and the Humanities

WHAT is pothenology? Sir Gavin de Beer tells us in his Rickman Godlee Lecture on "Science and the Humanities", delivered on October 25 at University College, London (London: H. K. Lewis and Co., Ltd. 2*s*. 6*d*. net). Much harm is done, in his opinion, by ignoring the essential differences between the collectors of Nature's answers and the compilers of men's thoughts. In a witty survey of the background of these differences, he emphasizes that "the only way to acquire a knowledge of scientific methods is in a laboratory, working with one's hands . . . while the only way to grasp the meaning of the humanities is to study men". He deplores the capture of precocious potential scholarship winners and their premature cramming "like geese". This has two harmful results. The first is the penalizing of the late developer. As he says: "The premium which we place on precociousness works directly against the processes which have made man what he is and may make him into *Homo sapientior*". The second is that general subjects are displaced from the boys' or girls' education, perhaps for ever. The effect of this, in his opinion, bears more heavily on science than on the humanities. Sir Gavin considers that one of the secrets of happiness in life is "the selection of the appropriate carrot to set before one's nose and that of other people". His particular carrot is "pothenology"; and to illustrate what it really means he treats his readers to three of his own pothenological researches: Hannibal's route over the Alps, the origins of the Etruscans and the real cause of Gibbon's death. But does he really believe that Newton and Darwin would not have "won scholarships on our existing system"? That is a most unpothenological statement to make.

Institute of Seaweed Research

SINCE the end of the War a new industry has been built up in Britain using more than forty thousand tons annually of a crop which, until recently, was looked upon as worthless. Whereas a few years ago there was only one very small alginate production unit in Scotland, there are now eight factories solely concerned with seaweed processing, which are served by an additional nine collecting and air-drying units. The current output of seaweed meal and alginates from these Scottish factories, together with the alginates and carragheenin produced in five further factories in England, has a sales value exceeding £1 million per annum. Britain's seaweed industry has now a larger output than that of any other country except Japan and the United States. This development has resulted from the combined efforts of scientists and industrialists, backed by the assistance freely given by government officials and by hundreds of interested individuals from all walks of life. A major contributory factor was the setting up in 1944 of the Scottish Seaweed Research Association "to determine whether the possibility existed of creating a stable Scottish seaweed industry which could compete with those of other countries and at the same time provide a considerable part-time crofter industry in the Highlands and Islands". The work of the Association during 1945–55, which was renamed the Institute of Seaweed Research in 1951, is described in a report which may be obtained from its Secretary at Inveresk, Midlothian, Scotland.

Tobacco and Smoking

IN a well-documented article in *Health Education* (14, No. 3; September 1956), Dr. Horace Joules shows that in 1955, 11,900,000 men aged sixteen and more were smoking an average of 15·3 cigarettes a day in Great Britain; the average consumption of 6,300,000 women smokers was 8·1 daily. Of these, 65 per cent of men and 40 per cent of women more than sixteen are regular smokers; 87·3 per cent of male doctors more than thirty-five years old have similar habits. The present yearly death-rate from cancer of the bronchus of 17,000 in England and Wales is shown to be associated mainly with smoking, especially cigarettes. This disease has caused 100,000 deaths in the past ten years, and reasons are given for suggesting that this is only the early stages of an epidemic which will result in half a million deaths in the next twenty to thirty years. Preventive action by the medical profession and the Ministry of Health it is thought, might be rapidly helpful. The mortality and morbidity from bronchitis are greater in Britain than in any other country where statistics are available. The part played by smoking in these conditions is important. The question is posed: Are there advantages from smoking which compensate for the known ill-effects on health? The answer according to Dr. Joules, must be an emphatic no.

Isotopes Commercially available in North America

"THE Isotope Index" published by the Scientific Equipment Corporation, Indianapolis 19, Indiana (U.S.A. and Canada, 2 dollars; elsewhere, 2.50 dollars), is the first up-to-date (April 1, 1956) complete guide to the isotopes and isotope-labelled compounds available commercially and produced or sold by American or Canadian suppliers. Some two thousand items are listed from more than forty different suppliers. In genoral, the information given has been taken from the suppliers' catalogues or price sheets Radioactive isotopes and labelled compounds of carbon-14, iodine-131, phosphorus-32 and sulphur-35 are dealt with in the first section, with the isotopes arranged in alphabetical order by name of element and then by atomic weight. The half-life, principal radiation, the forms in which the isotope is available and the cost are quoted, together with a reference to the supplier. In the next section stable isotopes and the labelled compounds of carbon-13, hydrogen-2 and nitrogen-15 are listed, followed by information on available radioactive calibration standards, radiographic and therapeutic sourcos, and a complete list with names and addresses, of the suppliers referred to in earlier sections. Finally, a brief section describes the recently revised licence requirements of the Atomic Energy Commission in the United States.

Endocrinology of Invertebrates

IN July 1955, immediately before the International Congress of Anatomy, an informal symposium on the endocrinology of invertebrates was held in Paris This highly successful meeting was organized by Dr. L. Arvy and Dr. M. Gabe, of the Sorbonne, and by Dr. B. Scharrer, of the Albert Einstein College of Medicine in New York, and was attended by some three dozen workers in this field. The communications have now been published (*Ann. Sci. Nat., Zool.* 18 (fasc. 2), 125–337); and they form a most useful cross-section of the recent developments in this subject. The Swedish workers Östlund and Fäng (Lund) describe the isolation in a highly purified state of a chromatophorotropic principle from the eyestalk of the shrimp *Pandalus*. The *Y* organ of Crustace discovered by Gabe has been shown by Echalier another French worker, to control the moulting o decapod crustaceans. Karlson (Tübingen) describe the extraction from the silkworm of the moultin hormone 'ecdyson'. This has now been obtained i crystalline form and proves to be a non-nitrogenou substance with a molecular weight of about 300 Another important contribution is that of Charniaux Cotton (Paris), who has obtained clear evidence that an androgenic gland, quite separate from the gonad controls the primary and secondary male characters of the amphipod *Orchestia gammarella*. Other papers deal with the cytology of neurosecretory cells in many groups of invertebrates, with moulting, metamorphosis, and changes of phase in insects, the possible role of hæmocytes in insect growth, and the part played by humoral factors in the discharge of gametes in certain molluscs.

Iboga

THE stimulant properties of the iboga plant have long been known to various Central African peoples (*S. Afr. J. Sci.*, 53, No. 1; August 1956). The pygmies chew iboga leaves and stalks before certain tribal ceremonies during which they must remain awake for several days when they are continually drumming on their tomtoms. Other tribes use the plant for initiation ceremonies when adolescent boys are left alone to roam the forest for five days, living solely on the iboga plant. Hunters of certain tribes also consume iboga before undertaking particularly long and dangerous treks through the forest. French chemists, who have been carrying out research on the plant over the past ten years, have now succeeded in extracting alkaloids from which they can manufacture a stimulant with very little toxic effect.

The Science Masters' Association : Annual Meeting

THE annual meeting of the Science Masters' Association is to be held during January 2–5 in the University of Cambridge, under the presidency of Sir Alexander Todd, professor of chemistry in the University, who will speak on "The Scientist—Supply and Demand". There will be discussions on "Technical Education and the Schools", introduced by Dr. K. B. Hutton, of Hatfield School, on January 4; and on "The Recruitment and Training of Science Teachers", with particular reference to secondary modern schools, introduced by Mr. W. H. Palmer, of Homerton College, Cambridge, and Mr. C. L. Brereton, warden of Bottisham Village Centre. Lectures to be given include "Science in the Universities and Schools" (Prof. N. F. Mott); "Diseases and Problems of Population" (Prof. A. L. Banks); "Some Recent Advances in the Chemistry of Fluorine" (Prof. H. J. Emeléus); "Botanical Monkeys" (Mr. E. J. H. Corner); "The Silicones" (Dr. P. Sykes); "Radio Astronomy" (Mr. L. Ryle); "Antarctica To-day" (Dr. G. C. L. Bertram); and "The Expanding Universe" (Dr. R. A. Lyttleton). Prof. J. F. Baker and the staff of the Cambridge Faculty of Engineering will be responsible for an evening lecture. There will be the usual exhibitions by members and by instrument manufacturers and publishers, and receptions at the Guildhall and in King's College. The Science and Religion Group of the Association will meet on January 5. The programme of the meeting can be obtained from the Annual Meeting Secretary of the Association, 93 Westbourne Road, West Hartlepool, Co. Durham.

University of Sheffield

THE following appointments have been made in the University of Sheffield: Dr. R. S. Tebble, senior lecturer in physics; Dr. J. F. Wallace, lecturer in mechanical engineering; Dr. R. G. Ward, lecturer in metallurgy. Dr. W. J. P. Neish has been appointed to the James Morrison Research Fellowship, and M. F. Sheff to the John Stokes Research Fellowship. The following members of staff have resigned: Dr. R. C. Cass, lecturer in chemistry; A. R. Curtis, lecturer in applied mathematics and Dr. D. W. Wakeman, lecturer in metallurgy.

The Night Sky in December

NEW moon occurs on Dec. 2d. 08h. 12m., U.T., and full moon on Dec. 17d. 19h. 06m. The following conjunctions with the Moon take place: Dec. 11d. 20h., Mars 5° S.; Dec. 24d. 12h., Jupiter 6° N.; Dec. 29d. 13h., Saturn 0·7° N.; Dec. 29d. 19h., Venus 0·2° S. In addition to these conjunctions with the Moon, Saturn is in conjunction with Antares on Dec. 21d. 17h., Saturn being 6·3° N., Venus with Antares on Dec. 26d. 10h., Venus 5·8° N., and Venus with Saturn on Dec. 26d. 21h., Venus 0·5° S. There will be a partial eclipse of the Sun on Dec. 2, but at Greenwich only a small part of the Sun will be seen to be eclipsed at sunrise, the eclipse ending a few minutes after sunrise. Mercury is an evening star, but conditions for observation are not favourable. Venus is a morning star, rising at 4h. 45m., 5h. 25m. and 6h. 10m. on December 1, 15 and 31, respectively, but it will be rather low for good observation from the British Isles. Mars is visible during the evenings, setting at 1h. 00m., 0h. 50m. and 0h. 35m. on December 1, 15 and 31, respectively; its stellar magnitude decreases during the month from −0·4 to +0·3 and its distance increases from 73 to 97 million miles. Mars is moving eastwards in Pisces, being south of δ Piscium at the end of the month. Jupiter rises at 1h. 10m., 0h. 20m. and 23h. 25m. at the beginning, middle and end of the month, respectively, and is east of β Virginis; its stellar magnitude is −1·6, its distance in the middle of the month is about 510 million miles. Saturn is too close to the Sun for observation. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Dec. 7d. 19h. 21·3m., ν Aqr. (*D*); Dec. 10d. 20h. 14·3m., ϰ Psc. (*D*); Dec. 20d. 21h. 29·0m., 60 Cnc. (*R*); Dec. 21d. 3h. 29·7m., ϰ Cnc. (*R*). *D* and *R* refer to disappearance and reappearance, respectively. The Geminid meteors are active during December 9–13, with a maximum near the latter date, but conditions are not favourable for observation. Winter solstice occurs on Dec. 21d. 21h.

Announcements

THE Ciba Foundation is offering not less than five awards, of an average value of £300 each, for papers on research relevant to basic problems of ageing. In making the awards, preference will be given to younger workers. The work submitted should not have been published before May 31, 1956, and the paper, which may be in the candidate's own language, should not be more than seven thousand words in length, with a summary in English not exceeding 3 per cent of the paper. Entries must be sent in not later than January 31, 1957, to the Ciba Foundation, 41 Portland Place, London, W.1, from which application forms and further information can be obtained.

IN *Nature* of November 10, p. 1033, an announcement was made of the presentation of the Robert Roesler de Villiers Award to Dr. J. F. Loutit. This award was in fact given for research described briefly in an article in *Nature* of March 10, 1956, entitled "Cytological Identification of Radiation-Chimæras", by Dr. C. E. Ford, J. L. Hamerton, D. W. H. Barnes and Dr. J. F. Loutit, and is being shared between these four authors.

BIOLOGY OF AGEING

A SYMPOSIUM on the biology of ageing was held by the Institute of Biology at University College, London, during September 27–28. Papers covered a wide and heterogeneous field, the first day being devoted to the biological and cytological, and the second to the psychological, industrial, nutritional and genetic aspects of age processes.

Sir Cyril Hinshelwood (University of Oxford) described the changes which characterize the decline of cells in non-proliferating bacterial cultures. Studies of the exchange of radioisotopes between non-dividing cells and the medium suggest that the reversal of synthetic enzyme activities which takes place under these conditions is accompanied by active synthesis elsewhere in the system ; but this re-utilization of the labelled materials is incomplete, and there is a steady leakage of activity into the medium. The near-random decline of such a cell population, which is a possible source of analogy with the behaviour of populations of post-mitotic tissue cells, may be due to the coincidence of a number of periodicities, the death of any one non-dividing cell occurring when several cyclical processes of resynthesis happen to reach a minimum simultaneously.

Dr. O. V. S. Heath (Imperial College, London) dealt with the mechanism of the growth check which accompanies the flowering of some higher plants, and with sequential changes in the composition and shape of leaves produced by meristems, as examples of two age changes in the life-cycle of plants. He described experiments suggesting that the change-over from growth to reproduction, which produces marked checking in most plants, and is fatal in annuals, is not wholly a nutritional effect.

Dr. A. Comfort (University College, London) described the importance of vertebrate vital statistics in the study of the phylogeny and comparative physiology of animal ageing. Actuarial senescence has been studied in laboratory populations of guppies (*Lebistes reticulatus*) under experimental conditions. Survival curves of a great many non-domestic vertebrates tend to approach an arithmetic straight line, the number of deaths being constant in unit time. Some advance has recently been made in compiling life-tables for zoo animals ; but among laboratory mammals they are available only for rats and mice, and search is being made for analysable records to indicate age-mortality relations in birds, marsupials and poikilotherms. Important new information of this kind is being obtained by Prof. F. Bourlière (Faculty of Medicine, Paris), whose paper was presented in his absence, and by his collaborators working on the growth and fertility of vertebrates in the wild, both by means of ringing studies and through the use of techniques of ageing reptiles by inspection—the French workers are particularly concerned with the effects upon the life-span of metabolic factors such as those due to hibernation and climate, and are attempting to compare the longevities of populations in warm and cold latitudes.

Dr. G. H. Bourne (London Hospital) described striking differences in enzyme distribution, revealed by histochemical methods, between tissue cells of young and old rats, with a gross increase in the alkaline phosphatase, particularly of the Purkinje cells, but also in liver, kidney and elsewhere. These changes are not confined to cells the life of which is equal to that of the animal but occurs also in the 'young' cells of old animals. Dr. G. I. M. Swyer (University College Hospital) gave an account of the progress recently made by a number of workers in describing the changes in output of individual steroid hormones with the advance of age in man. Of the α-ketosteroids, the 11-deoxy fraction decreases most regularly with age in both sexes, the 11-oxy-17-keto fraction less, and the 11-oxyetiocholanones least. Although human ageing is quite certainly not a simple consequence of steroid deficiency, the separation of these differently reacting components has already opened the possibility of more effective replacement therapy in the treatment of some consequences of senility.

Dr. H. M. Sinclair (University of Oxford) discussed two nutritional factors in the timing of human senescence—the effects of rapid growth in childhood and of overfeeding in the adult upon length of life, and the possibility that the arterial diseases of human old age are direct or indirect consequences of a deficiency of unsaturated fatty acids due to changes in dietary habits over the past century. He described experiments suggesting that not only the total intake but also the isomeric structure of unsaturated fatty acids in the diet are important determinants of atherosclerosis, and that the requirement of these substances is much higher in men than in women.

Dr. J. Maynard Smith (University College, London) gave an account of genetical research on the relation of longevity to vigour. Although there is a correlation between parental and child longevity, this is much smaller than the sib-sib correlation, and only one-quarter that for stature between parent and child. In laboratory stocks, heterozygosity appears to be the most important single correlate of long life, which is part of the general complex of vigour found in hybrids.

Other papers dealt with the demographic aspects of ageing (Dr. B. Benjamin, Office of the Registrar-General), the functional changes with age in man and their effects on employability (Prof. W. Hobson, University of Leeds), the use of the working life in man and animals as a measure of ageing (F. le Gros Clark) and the psychological changes occurring with age in man (Dr. A. Heron, Medical Research Council Occupational Research Unit, University of Liverpool). The papers and subsequent discussion are to be published later.

FEEDING LABORATORY ANIMALS

THE nutrition of laboratory animals was the subject of a symposium, organized jointly by the Nutrition Society and the Laboratory Animals Bureau, and held at Guy's Hospital Medical School, London, on October 6. It was the 105th meeting of the Nutrition Society and the fifth in the series of Laboratory Animals Bureau symposia. Dr. S. K. Kon (National Institute for Research in Dairying) was in the chair, and nine papers were presented.

In the opening paper, Dr. W. Lane-Petter (director, Laboratory Animals Bureau, Medical Research Council Laboratories, Holly Hill, London) spoke of modern ways of feeding laboratory animals. He traced the development of the currently popular compressed compound diets, and directed attention to their undoubted advantages on the score of convenience for the laboratory worker, as well as their probable drawbacks and the inherent weaknesses of this system of alimentation. The incorporation of all the necessary ingredients for complete nutrition, intimately mixed, in a cube or pellet that will not deteriorate after compounding, is a formidable task—even an impossible one. The suggestion that future diets should contain at least a proportion of unprocessed food—whole cereal grains, for example—points to one possible development in a field still wide open for further investigation.

Mr. J. Cassidy (H. C. Styles (Bewdley), Ltd.) showed what can be expected of the conscientious manufacturer in the quality control of ingredients. In Great Britain, diets are made to published formulæ, and the manufacturer assumes, if sometimes with scepticism, that these formulæ are satisfactory. His job is to compound them and present them in a suitable form; but it does not include devising them or testing their adequacy experimentally. If the total market for such diets were larger and not, as at present, dissipated among several manufacturers, there would be more of the commercial incentive to produce really good diets that make the manufacture of farm animal feeds so competitive.

Some of the difficulties of assessing laboratory animal diets were described by Miss G. G. Weeks (Laboratory Animals Bureau). Growth is of little value as a measure of the adequacy of a diet, because growth can mean so many things. Life-time performance, she suggests, in terms of weight-gain, body composition, reproductive performance and longevity, is the only satisfactory criterion, but in this she begged a vital question. The choice of diet is influenced by the use to which the animals are to be put; some nutritional studies require an animal to have low reserves of, say, vitamin D; reproductive performance is of paramount importance for the breeder; a slow increase of weight over a critical period of growth may be of chief interest to the bioassayist; and longevity may, or may not, be irrelevant.

Dr. W. F. J. Cuthbertson (Glaxo Laboratories, Ltd.) showed that some commonly used diets for rats and mice contain only marginal amounts of certain essential nutrients; indeed, the margin may be altogether too narrow for safety. Semi-synthetic diets might have a wider usefulness than 'natural' feeds if standardization of the diet at optimum levels were the objective, and the cost of such diets might be more than offset by the gain in uniformity and reliability of the product.

In discussing the problems encountered in studying the nutrition of cats, Mrs. P. P. Scott produced some valuable data from her own experimental breeding and raising of cats at the Royal Free Hospital School of Medicine. She finds that satisfactory growth of kittens depends largely on an intake of protein at a very high level. It was clear that much of this evidence came from experiments on animals too small in number to be impressive, but the results of studies so far carried out show that breeding and raising cats under laboratory conditions hold great promise.

Adequate diet is a necessary condition of healthy animals, and Dr. J. S. Paterson (superintendent, Allington Farm (Ministry of Supply), Porton) illustrated this with particular reference to guinea pigs. Apart from the assimilable components of a diet, there may be—and in the case of guinea pigs, there is—a need for fibre or roughage. Deficiency of roughage, which is usually supplied in the form of hay, is often associated with dental abnormalities leading eventually to the mechanical starvation of the animal. However, Dr. Paterson has succeeded in raising a line of guinea pigs, appearing in his colony perhaps by a chance mutation, where fibre requirements are such that hay can be omitted from the diet without ill effects.

In an interesting paper on monkey welfare, Miss F. M. Hume recounted her experiences over very many years at the Lister Institute with the nurture of different species of primates. Cage paralysis, a condition that has disappeared from laboratory animal houses, was formerly due to rickets, and the treatment was sunlight through 'Vita-glass', ultra-violet irradiation, or vitamin D by mouth. Miss Hume's obvious regard for the welfare of caged primates sounded a humane—dare one say cautionary?—note in a meeting in which there was a wide range of attack on a difficult problem.

Dr. G. H. Bourne (London Hospital Medical College) reviewed current knowledge of canine nutrition and also touched on the dietary requirements of other carnivores. He referred to the lipæmia and lipuria of tigers consuming large quantities of fat; the latter condition, by coating the floors of their cages with fat, can be an embarrassment and a danger to the keeper.

Finally, Mr. D. B. Bellis (Food Research Department, Unilever, Ltd.) spoke about the nutrition of the baby pig, which has some promise of usefulness as a laboratory animal, and particularly of the problems raised by premature weaning. Substitutes for sow's milk can produce results comparing satisfactorily with those of suckling.

It would be exceptional for a meeting of this kind to provide all the answers to such a difficult problem as feeding small animals under laboratory conditions, and this symposium was no exception to the rule; but the subject did gain something in clarity of definition. The difference in outlook between the chemists on one hand, and the biologists on the other, was striking. The chemist is satisfied, it seems, to offer the animal whatever most conveniently (for himself) contains nutrients that will make the animal grow, reproduce or live as long as it is required to live, and the animal either eats or starves. A very short time will suffice to persuade it to eat, even without relish, whatever edible material is offered. But the biologist might be forgiven for thinking that the presence or absence of relish is relevant, and that an animal eating food it likes may differ from one eating because it has to. The study of acceptability of food items among animals is notoriously full of pitfalls, especially in animals kept under conditions far removed from the natural; but to ignore it may be to ignore one possible method of investigating what a particular animal really needs to eat to support perfect health. Subject to rigid safeguards—all the more necessary when dealing with creatures of the laboratory and with sophisticated or processed foods—the study of food preferences is not entirely irrelevant.

The diagnosis of perfect health introduces further difficulties. Sub-optimal nutritional states do not necessarily kill or sterilize, and if they do not they may be overlooked. For example, very many colonies of albino rats show porphyrin staining of the fur, particularly on the back of the neck—sometimes called 'red collar disease'—but this is seldom regarded as abnormal for it appears not to interfere either with growth or with reproduction. Yet it must be asked whether such a condition is normal; the fact that it is so widespread does not make it so, for it is not universal. Only the sight of a colony where it is never seen is likely to cause anxiety in one where it is prevalent.

Standardization of diets is obviously desirable; but to give a diet a name and a formula does not automatically achieve this end. It is here that the manufacturers and the consumers can profit each other by much closer collaboration than at present exists. If animals are to subsist on composite complete manufactured diets—and at least one speaker questioned the advisability or possibility of this—then the devising and the compounding of these feeds are interrelated. Nor will chemical standardization secure any useful purpose if the feed, as offered to the animal, is sub-optimal in composition. In this respect strain differences in dietary requirements should be noted and allowed for. The first task is still to provide a diet that gives the animal all that it needs, and if possible a little to spare; when this is achieved, standardization begins to have some meaning.

Finally, there is the humane aspect. We cannot do without our laboratory animals, and many would not wish to be deprived of this source of interest. For both scientific and humane reasons, they must be treated as well as possible, so that their lives, which serve us so well, shall not be a burden to them. Good feeding will help to this end.

The papers presented at this symposium will be published (*a*) in the *Proceedings of the Nutrition Society* and (*b*) in Laboratory Animals Bureau Collected Papers, Vol. 5 (obtainable from the Bureau at the Medical Research Council Laboratories, Holly Hill, London, N.W.3).

SEMICONDUCTORS AND PHOSPHORS

INTERNATIONAL COLLOQUIUM

AN international colloquium on semiconductors and phosphors was held at Garmisch, southern Germany, during August 28–September 1. It had the support of the International Union of Pure and Applied Physics, and was opened by Prof. W. Gerlach. Its scope may be judged from the following figures: ninety papers were read, there were about 450 scientific participants, and nineteen countries were represented, including the U.S.S.R., Eastern Germany, Czechoslovakia, Poland and Hungary.

W. Schottky, in his introductory lecture, distinguished (*a*) papers the main emphasis of which was on states and events which concerned the electrons, and (*b*) papers which dealt with experiments and considerations devoted in the main to the manipulation of substances.

Electronic Properties

The magnetic susceptibility contribution (χ_L) which arises from the current carriers in a semiconductor may be recognized by its dependence on temperature. Prof. G. Busch (Zurich), using a reduced representation in which this quantity is divided by a constant independent of temperature and characteristic of a given specimen, showed that germanium, InSb and $InP_{0 \cdot 2}As_{0 \cdot 8}$ appear to have abnormally low values of $|\chi_L|$ at low temperatures. The origin of this effect remains to be investigated. Since relatively little is as yet known of the effect of impurities on the magnetic susceptibilities of semiconductors, the experiments of D. Geist and T. Hehnen (Cologne) on iron-doped germanium were also of interest. Cyclotron resonance experiments on InSb at room temperatures were reported by H. A. Gebbie (U.S. Naval Research Laboratory), and were found to yield an effective electron mass $m^* = 0 \cdot 015m$, as compared with the value $0 \cdot 025m$ obtained from transport phenomena. Although different averages over the energy surfaces are involved, this difference is not clearly understood. Paramagnetic resonance experiments on silicon carbide crystals were reported from the Philips Laboratory by J. S. van Wieringen, who contrasted the effect of doping with nitrogen, when three resonance peaks are observed, with the effect of doping with boron or aluminium, when only one peak is found. Interesting speculations concerning the nature of the nitrogen impurities in the lattice (namely, that the trapped electron can be in an *s*-state and near a nitrogen nucleus) are possible. In another lecture the appropriate equilibrium probabilities for the trapping of electrons by singly- or multiply-charged defects which have several trapping levels were also discussed.

Transport phenomena. Among the non-equilibrium properties, considerable interest was shown in transport phenomena. Here C. Herring (Bell Laboratories) and J. E. Parrott (A. E. I., Aldermaston) discussed consequences of the fact that phonons of long wavelength are less likely to suffer collisions leading to change of direction than phonons of short wave-length, so that they can contribute strongly to thermal conduction. By exerting a drag on the charge carriers, they are also responsible for an additional term in the thermoelectric power. Good single crystals, low concentrations of impurity and low temperatures are required to show up the effects of these phonons. Considerable interest was also shown in the magneto-resistance ratios. Thus, a negative ratio was found for gallium arsenide below 40° K. (R. Broom, R. Barrie and I. M. Ross, Services Electronics Laboratory), and delicate micromanipulation to measure the effect in graphite was also reported (R. G. Breckenridge, National Carbon Co., U.S.A.). From the R.C.A. Laboratory (M. Glicksman) interesting results on germanium–silicon alloys were described which suggest that pure germanium galvanomagnetic properties occur up to a composition of 10 per cent silicon, and pure silicon galvanomagnetic properties occur above 25 per cent silicon. A paper (H. Weiss, Siemens Schuckert, Erlangen) and discussion on the thermal conductivity of InSb showed that further experimental clarification is required in this difficult field before all experiments can be reconciled with each other. Further work on the photoelectro-magnetic effect was reported by British workers (T. S. Moss, Royal Aircraft Establishment; G. G. Macfarlane and V. Roberts, Radio Research Establishment).

Barrier-layer physics. Some attention was given during the conference to those aspects of transport phenomena which may be grouped under the heading of barrier-layer physics. In a general report, E. Spenke (Siemens Schuckert, Pretzfeld) directed attention to large-area silicon rectifiers, designed by Siemens and ready for production, which pass about 250 amp. at 1 V. forward and 1 amp. at 1,000 V. reverse voltage. The advantages over germanium rectifiers may be traced back to some extent to the larger energy-gap in silicon. The manufacture of very pure silicon by the floating zone method is an essential factor in the production of these rectifiers, and the most suitable reactions for this purpose were reported to be :

$$SiCl_4 + 2H_2 = 4HCl + Si$$

or

$$SiHCl_3 + H_2 = Si + 3HCl$$

Two papers from the University of Reading reported new work on germanium contacts (J. D. Nixon and P. C. Banbury ; D. Hanemann and A. J. Mortlock).

Surfaces. Closely connected with barrier layers are investigations of surfaces. Here, J. Bardeen (Illinois) showed clearly that reasonably reliable methods for determining the distribution of surface states are now available, and that future work must try to determine the chemical nature of the fast and the slow states known to occur on etched surfaces of germanium and silicon.

Life-times of excess carriers. About eight papers dealt with another aspect of typically non-equilibrium properties, namely, the life-times of excess carriers in a semiconductor. A paper by W. Scanlon (U.S. Naval Ordnance Laboratory) seemed to show conclusively that the moving line of light method for the determination of life-times is unsuitable for natural single crystals of lead sulphide, unless they are cleaved in an inert atmosphere. A life-time (τ) of 1 μsec. as obtained by this method (and judged to be the true volume life-time by comparison photoelectric-magnetic measurements) may be raised to many times this value by the admission of other gases. By using an etching solution containing thiourea to reveal densities of etch pits (N), a relation $\tau = \text{constant}/N$ was established, and the conclusion that life-time is independent of conductivity was also inferred. This important contribution will undoubtedly stimulate re-examination of previous work in this field.

Carrier trapping due to dislocations was discussed by H. Kawamura (Osaka, Japan). He inferred 2–3 A. as the effective width of a dislocation in germanium so far as trapping is concerned. The dependence of life-times in silicon on temperature were shown to be in contradiction with simple trapping models by M. Zerbst and W. Heywang (Siemens Halske, Karlsruhe).

Optical properties. If it is borne in mind that excess carriers may end their lives by radiative transitions, the connexion between life-times and optical properties becomes clear. J. R. Haynes and K. G. McKay (Bell Laboratories) spoke about this topic with special reference to the production of radiation in silicon due to processes involving thermal and high kinetic-energy current carriers respectively. Haynes showed that the energy spectrum of recombination radiation at liquid-nitrogen temperatures has a peak at 1·1 eV. (due to interband transitions), and that other peaks exist, the separation of which from this main intrinsic peak yields known impurity activation energies. This was found to be the case for indium, gallium and boron impurities, while doping with boron and arsenic jointly also produced unexplained peaks. The spectral distribution due to recombination processes which involve 'hot' electron and hole gases (that is, gases which are out of equilibrium with the lattice) was shown by McKay to be due to band–band transitions as well as optical transitions in one and the same band. By applying reverse bias to a p–n junction formed on a p-type silicon crystal with a layer (2μ thick) of n-type silicon, it was possible to observe spots of red light near breakdown. The current–voltage characteristic near breakdown had a series of discontinuities and it seemed that at each discontinuity a new spot made its appearance. From a correlation of electrical and optical data the diameter of a breakdown region could be estimated at about 500 A. In germanium the current discontinuities, but not the light spots, have been observed to date.

Phosphors. Discussion of light emission by monatomic semiconductors leads on to the general problems of luminescence and phosphors, which are of technical importance for television screens, advertisements and, possibly in the future, for domestic illumination. W. Hoogenstraaton (Philips, Eindhoven) reviewed the non-electronic energy transport in phosphors. The possible importance of excitons was discussed rather speculatively here, and at various points throughout the meetings. Absorption spectra characteristic of excitons have been reported by H. Masakazu (Japan), E. Gross (U.S.S.R.) and S. Nikitine (France). Though some reserve must be maintained with regard to the interpretation of these spectra, there was lively interest in the properties of excitons. Thus, arguing from photoconductive experiments, the conjecture was even made that the life-time of excitons may possibly be as long as 10^{-3} sec. and their diffusion length as long as 3 mm. in single crystals of cadmium sulphide at room temperature (M. Balanski and I. Brosor, Berlin). A theoretical paper concerning their stationary and non-stationary properties was given by H. Haken (Erlangen).

Manipulation of Substances

In the large group of papers dealing with the manipulation of substances, E. Billig (A.E.I., Aldermaston) gave a review of growth and defects of semiconductor crystals (supported by a short film on crystal growth). A number of problems raised here and in discussion (and also in connexion with a paper by I. P. Penning (Philips, Eindhoven)) concerned the possibility of the motion of a dislocation during etching, the deposition of copper at dislocations, the possible production of dislocations by thermal stress near the crystal – melt interface, etc. In a review of the related problem of the incorporation of foreign atoms in the lattice, a new notation for defects in crystals was suggested (F. A. Kröger and H. J. Vink, Philips, Eindhoven). The diffusion of defects was also considered ; the effect of the surface was discussed by F. M. Smits, R. C. Miller and R. L. Batdorf (Bell Laboratories), the diffusion of activators in zinc sulphide by H. Ortmann (Berlin), and the diffusion of hydrogen in zinc oxide by J. J. Lander (Bell Laboratories).

Bombardment of semiconductors. A group of papers on manipulative techniques included some on the bombardment of semiconductors. H. Y. Fan (Purdue, U.S.A.) discussed recent work in this field, and compared the effects (which are not identical) of electron and α-particle irradiation of germanium, in addition to reporting results on the effects of irradiation on silicon, InSb and InAs. R. Gremmelmaier and H. Welker (Siemens Schuckert, Erlangen) described the use of InP as a detector of neutrons, by taking advantage of an (n,γ)-process due to the reaction of slow neutrons with indium, and subsequent conversion of the indium isotope with the emission of β-radiation. The γ- and β-rays produce electron-hole pairs, so that at an InP p–n junction an e.m.f. is developed the decay of which after irradiation enables one to infer the neutron flux.

Papers on specific groups of materials included a discussion of the mechanism of luminescence in silver halides (Z. Matyaš, Prague). New ternary compounds with semiconductor properties were discussed briefly in two papers, and D. A. Wright (General Electric Co., Wembley) reported on the properties of bismuth telluride, which is suitable for studying the problems of thermoelectric refrigeration. Organic systems were also discussed. H. P. Kallmann (New York) put forward considerations which suggest that the energy transfer in liquid organic systems is by collision rather than by irradiation. He also reported experiments on photoconductive effects in organic crystals in which the motion of holes appears to dominate.

Papers submitted to the colloquium, but not read, included one on the electrical properties of some binary compounds by D. N. Nasledov (Leningrad) and another on the breakdown of p–n barriers by B. M. Wul (Lebedew Institute, Moscow), and participants of the colloquium were glad to be able to discuss with the authors recent Russian work in these and related fields.

It is a tribute to the work of the organizers that the texts of most of the invited papers and the abstracts of most short papers were in the hands of the participants before the meeting. Nevertheless, there was comparatively little discussion in the open meetings; though, if time had been allocated explicitly to discussion, there would have been numerous contributions from the floor, judging from the many fruitful private conversations which were proceeding between meetings.

It is regretted that several interesting papers cannot be mentioned here, but enough has probably been said to indicate that a very wide field was covered. While it is true that no new band structure calculations were reported, and impurity band conduction was touched on only incidentally, it is in fact difficult to think of any other basic topic which was not raised in one or other of the papers submitted. The proceedings will be published early in 1957 as volume 4 of "Halbleiterprobleme" (Friedr. Vieweg u. Sohn), with each contribution in its original language.

P. T. LANDSBERG

EXTRUSION AND ROLLING PROCESSES

THE September conference of the British Society of Rheology held in Sheffield during September 27–28 had as its title "Extrusion and Rolling Processes". The varied interests of members of the Society were fully illustrated by the wide scope of the papers presented. Each had in common some particular aspect of rheological behaviour. The conference, consisting of the presentation of six papers and the attendant discussions, was opened by the president, Prof. J. G. Oldroyd (University College of Swansea).

"Some Applications of Rheology in the Investigation and Practice of Polymer Extrusion" was the title of a paper by W. F. O. Pollett (Henley's Research Laboratories). The simple screw extruder is extensively used in the electric cable industry for the application of dielectric and protective coverings, composed essentially of high polymers. Standard quantitative treatments of the theory of screw operation in conjunction with viscous materials have been based, erroneously, on the assumption that the thermoplastics and rubbers used in the cable industry exhibit Newtonian behaviour. The Ostwald de Waele relationship provides a somewhat closer approximation to practice within certain limits of screw design.

The use of different coloured materials is a standard method for mapping flow-paths in an extruder and can be supplemented by two complementary techniques. Strains can be 'frozen in' many high polymers by a reduction in temperature, and elastic recovery will afterwards occur if the temperature is again raised. The recoverable strains produced in plasticized polyvinyl chloride during its passage through the extruder can be stabilized in this way and their distribution studied by the reheating of suitable samples. Further, the temperature at which recovery occurs depends upon that at which the polyvinyl chloride was deformed. These methods have greatly assisted the correct design of T-heads used for the application of extruded wire and cable coverings. It has been shown that when material emerges from the screw channel, it converges towards the axis of the barrel in consequence of the Weissenberg effect. Unless the boundaries are suitably shaped, this will result in stagnant zones leading to decomposition of the polymer or to premature curing in the case of vulcanizable compositions.

When the conditions at the die are such as to favour the formation of high recoverable strains, there is a tendency for the exudate to exhibit a characteristic type of surface roughness probably caused by the stretching of the surface layers as the velocity gradient existing in the die is dissipated in the vicinity of the die mouth. This effect can often be avoided by an increase in temperature; or, if this is impracticable, by maintaining by special die design a shear-rate of 10^4–10^5 sec.$^{-1}$ for a sufficiently long time.

The determination of extrusion variables and the principal features of press design can be treated theoretically as shown by P. Feltham (University of Leeds) in his paper "A Simple Theory of the Criteria of Press Design and Process Efficiency in the Industrial Extrusion of Metals". In the direct extrusion process, work done by the ram is expended on useful plastic work in reducing the dimensions of the metal from A_0 to A, where A_0 is the cross-sectional area of the billet and A that of the extruded bar. Work is wasted due to friction at the billet/container interface, as well as on plastic work which does not yield a final plastic deformation. Since flow during extrusion is essentially streamlined, useless work of this latter kind is very small and is neglected in the theory. The maximum extrusion pressure can be shown to be: $\sigma_{\text{max.}} = Y_a \, [\ln(A_0/A)] \exp (4 \mu L'/D)$, where Y_a is the tensile yield stress of the fully work-hardened material at the extrusion temperature, μ is the effective coefficient of friction at the billet/container interface, L' is a length slightly smaller than the billet length and D is billet diameter. The strain-rate in the 'virtual die' formed by 'dead metal' near the true die orifice is approximately equal to

$(3V/D)\ln(A_0/A)$, where V is ram velocity. Y_a depends on strain-rate and temperature and can be obtained from high-temperature rheological data for metals at high strain-rates. Extrusion forces calculated from the theory for aluminium, copper and lead using a wide range of extrusion temperatures, extrusion ratios, ram velocities and billet dimensions showed very good agreement with experimental results. The maximum extrusion force $F_{\text{max.}} = A_0\sigma_{\text{max}}$ has a minimum for a given value of A_0 and fixed value of billet volume V. From the condition $\mathrm{d}F_{\text{max.}}/\mathrm{d}D = 0$, an optimum value of billet diameter D can be determined. Such a determination could be particularly valuable when using a press near its maximum capacity. At very high temperatures with high extrusion ratios, the back shear stress at the billet surface due to friction may exceed the tensile shear stress of the metal. When this happens, a thin skin of metal adheres to the contained wall after extrusion, and the maximum extrusion stress then becomes $Y_a[\ln(A_0/A) + (2mL'/D)]$, where $m = Y_b/Y_a$ and Y_b is the tensile shear stress of the billet in the surface region.

In "The Use of Optical Methods in the Manufacture of Plastic Sheet", H. H. Allen (British Celanese, Ltd.) pointed out that optical methods can be usefully employed to obtain information about rheological conditions of both product and process in the continuous production of both cast and extruded plastic film or sheet. The instruments used should be simple and robust, and preferably utilize some projection technique. One instrument recently developed, using a technique based essentially on the schlieren method, can detect normal and abnormal flow lines, 'cold-flow' patterns and any impurities and inhomogeneities.

Anisotropy often exists in thin plastic sheets and is generally caused by stresses due to flow in the extruder die or casting box. Orientation of sheet is of importance because of its general deleterious effect on physical properties. An interesting correlation exists between optical anisotropy and such physical properties as breaking strength and heat shrinkage, and its measurement can be used, therefore, to determine these important properties. Further, since its presence reflects to some extent the rheological behaviour of the process, it can be used to detect changes in operating conditions with consequent greater uniformity of product. Continuous measurement of optical anisotropy can be carried out by comparing on a screen the light transmission of the sheet and each of two pairs of crossed 'Polaroids'. This instrument also determines the direction of orientation. Divergence between extrusion or casting direction and direction of optical anisotropy indicates flow disturbance.

The theoretical aspects of milling and calendering were discussed by E. B. Atkinson (B.X. Plastics, Ltd.) in his paper "Milling and Calendering of Plastics". In the mills and calenders used extensively in rubber and plastics technology, a 'bank' of plastic material is built up at the entrance side of the roll 'nip' and is squeezed through the roll gap as a continuous sheet. The flow regime in the plastic in the region between the rolls and the magnitude of the stresses arising are of considerable interest to the plastics technologist and the design engineer. The theoretical treatments of Ardichvili, Eley and Gaskell were based on assumptions of doubtful validity. Except in the case of a high degree of slip (that is, with heavily lubricated compositions) the flow regime can be regarded as equivalent to the extrusion of plastic material through a slot of varying height, and the pressure distribution, roll thrust, and shaft torque determined by the shear stresses set up at the roll surfaces. Gaskell's treatment is based on these assumptions, but in its original form is not readily applied to non-Newtonian materials. Atkinson and Nancarrow have carried out a similar treatment based on an empirical power-law relationship between shear stress and velocity gradient. In this the pressure distribution, total roll thrust and shaft torque may be obtained from expressions which contain the rheological parameters, roll dimensions and speeds, and from tables of numerically evaluated functions which depend upon the size of the 'bank' of plastic in the 'nip' and the exponent of the power law.

Theoretical treatments of the rolling and extrusion processes are affected by a rise of temperature during the process. A paper on "Temperatures developed during Extrusion", by M. T. Watkins (Mechanical Engineering Research Laboratory, Department of Scientific and Industrial Research), was therefore of great interest. Suitable sub-presses were developed for the direct and inverted extrusion of rod and Hooker tubes and the inverted extrusion of tubular containers. The sub-press was set up for the appropriate extrusion and mounted in a 150-ton up-stroking hydraulic press. The extrusion load and punch stroke were measured by variable capacity gauges of the parallel-plate and concentric-cylinder types respectively. Temperatures within the slug were measured at four positions simultaneously by thermocouples protected by high-tensile steel sheaths, it having been established that these sheaths had little if any influence on the flow pattern. Rods, Hooker tubes and tubular containers of chemical lead Grade A, aluminium 99·5 per cent, copper E.R.H.C. and 70/30 brass were extruded at room temperatures at punch speeds of 1 to 30 in./min. All slugs excepting those used for studies on the effect of slug dimensions were of 1 in. and 2 in. diameter and of heights 1 in. and 2 in. respectively. The major factors contributing to the temperature rise inside the slug during extrusion were the reduction in area and punch speed. The highest recorded temperatures for the extrusion of lead and aluminium rod at 99·4 per cent reduction were 180° C. and 280° C. respectively, the thermocouples being located $\frac{1}{8}$ in. inside the slug. In the extrusion of lead at this reduction, an increase in punch speed from 1 in. to 5·5 in./min. resulted in an increase in observed temperature from 90° to 170° C. With aluminium at 94 per cent reduction under similar conditions, the temperature increased from 65° to 160° C.

The difficulties inherent in the theoretical treatment of hot rolling were emphasized by A. W. McCrum (British Iron and Steel Research Association) in a paper entitled "Theoretical Aspects of Hot Rolling". Despite its great importance technologically, the hot rolling process has received little theoretical treatment. Within the temperature-range of hot working, the frictional stress between the rolls and the stock approaches the yield strength of the material in shear, and as a consequence of this and the geometry of the process, the deformation is complex and in general is three-dimensional with the occurrence of appreciable increase in width (spread). A rigid theoretical solution of even the simplest problem, a rectangular bar between parallel rolls, is at present unobtainable without making many simplifying assumptions. Most of the early theories have been largely empirical, and only the analyses of Ekelund, Orowan and Sims can be said to have a theoretical basis. None of these treatments yields formulæ which can be widely used in practice. Of the many formulæ proposed for the calculation of the spread of a rectangular bar between parallel rolls, that of Ekelund is of reasonable accuracy but too complex for practical utilization. A recent formula derived by Hill combines accuracy with simplicity; but a parameter representing the effect of either friction or the deformation behaviour of the material must be determined in advance. The practical requirements of a satisfactory theory of hot rolling are: (*a*) prediction of roll force and torque to the required degree of accuracy, and (*b*) spread must be predicted so that the final product is within the required tolerance limits. Furthermore, this should be possible for all simple shapes such as diamonds, squares, ovals, etc. The problem is further complicated by the modern use of continuous multi-stand rolling, where a knowledge of stock entrance and exit speeds for a given velocity of roll surface is essential.

D. HARDWICK

THE BRITISH ELECTRICAL AND ALLIED INDUSTRIES RESEARCH ASSOCIATION

ANNUAL REPORT FOR 1955

IT is sad to record that within a few days after the presentation of the annual report for 1955 of the British Electrical and Allied Industries Research Association* to the annual general meeting of that body on May 2, the Association lost by death its director, Dr. Stanley Whitehead. Dr. Whitehead had served the Association for just over thirty years and he had discharged with distinction the duties of director for the past twelve years.

Since the report was issued, the Association's new laboratories at Leatherhead have been completed and with only a few exceptions the researches which were carried on at Perivale have been transferred to the new quarters and are already established there.

In the introduction to the report it is mentioned, under the heading of "Finance", that a quinquennial period covered by agreement with the Department of Scientific and Industrial Research for the award of grant will shortly come to an end and it is known that, in relation to renewal of grant, the new conditions will make the ratio of grant to grant-earning income less than under the present generous terms. With this in view, and taking account of the improved facilities for research provided by the new laboratories, the "Council is giving serious thought to the ways and means of securing the additional income necessary for the effective and efficient pursuit of the Association's functions".

As in previous years, the report gives brief summaries of the year's work in each of the research sections, together with a list of reports which have been issued or prepared during that period. There are also included a list of members of the scientific and administrative staff, the composition of the various standing committees, a list of those engaged in the Association's extra-mural researches and finally a full list of the membership of the Association.

Among the more important of the research items reported may be mentioned the discovery of a new form of intrinsic breakdown arising from mechanical instability in the electrostatic field (see *Nature*, **176**, 1225; 1955). This discovery occurred in the course of a research into the properties of irradiated dielectrics, as a result of which it had been shown that irradiation enables polythene, for example, to retain discharge resistance to a much higher temperature. It is also reported that a long-term investigation has been started on the thermal endurance of insulating materials, in which is included the ageing and hydrolysis of 'Terylene'.

In discharge physics a theory of the arc core has been developed which is based on the variation of thermal conduction with temperature. Further new theoretical work has been done on the electron emission from a cathode of low boiling point and on the motion of the cathode spot.

An improvement in the efficiency of utilization of electric cables should result from the publication during the year of a new rating table for paper and varnished cambric cables. These tables, used in association with a group of reports, enable advantage to be taken of higher temperatures allowed for certain types of cable, of variable loading and of a knowledge of the thermal properties of soil. Corresponding work on installation cables has already been incorporated in the thirteenth edition of the Wiring Regulations issued by the Institution of Electrical Engineers. Under "Circuit-Breaking", it is noted that the survey of rates of rise of re-striking voltage, which has already been made for the British 275-kV., 132-kV., and 66-kV. networks, has been extended to the 33-kV. system. This investigation and others of a similar character have utilized the Association's network analyser, and it is noteworthy that a number of these problems have required for their solution the special facilities which have been incorporated in this equipment.

In addition to the continuation of work on air blast and oil circuit breakers, it is reported that significant progress has been made on the rupture of heavy currents under low pressures and that an experimental continuously evacuated switch has interrupted the full output of the Perivale test plant.

There is increasing interest, arising largely from the chemical and oil industries, in flame-proofness and intrinsic safety. A new sectional committee has been appointed to direct an expanded programme of work in this field, which is being financed by special contributions from makers, users and the government.

A revised Code of Practice on Earthing is now nearly complete, and a survey has been carried out on the ageing of electrical installations in relation to the incidence of fires.

Research on the properties of high-pressure, high-temperature steam continues, and work has been started on the extension of the Callendar (1939) Steam Tables, the first region under investigation being that up to 5,000 lb./in.^{2} and 1,400° F.

A report will soon be published summarizing the results of tests for 10,000 hr. on the creep- and corrosion-resistance of steels for high-temperature service in steam plants.

The heading "Unclassified Researches" covers a group of six subjects which are as follows: astrophysics, fixed resistors, rotating electrical machines, measurement of current and voltage on high-voltage systems, storage and generation of electrical energy and the welding arc.

---

* British Electrical and Allied Industries Research Association. Thirty-fifth Annual Report (1st January, 1955, to 31st December, 1955). Pp. 141. (Leatherhead: British Electrical and Allied Industries Research Association, 1956.)

It is reported that work on the hydrogen–oxygen fuel cell has reached the stage at which a cell has been tested for more than 1,500 hr. and full-scale performance can now be predicted with confidence.

In relation to arc welding, it is stated that the surge injection system, a device developed by the Association which stabilizes the arc in the a.c. tungsten arc-welding process without generating radio interference and enables low-voltage plant to be used, is now in commercial production. There is also in this section a reference to the development of a novel method for the measurement of current at high voltage. This is a magneto-optical current transformer based on the Faraday effect.

Towards the close of the introduction, mention is made of a proposal to publish at intervals an *ERA Journal* which would aim at bringing out the actual and possible impact of the Association's researches on industry; the first issue of this journal appeared recently. JAMES GREIG

TECHNICAL INFORMATION SERVICES TO COMMERCE AND INDUSTRY

EARLY in 1955 the steering committee of the Regional Academic Board of the London and Home Counties Regional Advisory Council for Higher Technological Education asked its Librarianship Committee for advice on the feasibility of co-operation between county and municipal libraries in technical colleges, industrial firms and research associations in a given area to provide a scientific and technical information service which would be available to all local industrial and commercial concerns. Since that time the committee has examined schemes in operation, or planned, in the London and Home Counties region and in other parts of Britain.

Among these were the cities of Liverpool and Sheffield, a co-operative scheme between county boroughs in south-east Lancashire, as well as one operated by the Hertfordshire County Council. The committee notes that, from the evidence available, the needs of industrial firms vary from area to area and recommends that the schemes in being at the places visited should be brought to the notice of municipal and county libraries, and to local committees of the British Productivity Council in the region with a suggestion that consideration might be given to the development of similar schemes on individual lines to suit local needs.

The technical colleges themselves can do much to stimulate the use by industry of scientific and technical information services in the following ways: by developing the college library to form a valuable part of the teaching programme; by fuller use of the college library in the teaching programme than is the general practice at the present time; by training students in the use of the library's resources and other sources of information available to them in other libraries. If students are so trained during their years at college it is reasonable to expect that they will continue to turn to sources of information with which they are already familiar, in tackling the problems which face them later in industry and commerce. So, too, the link between the colleges and the industrial world will be progressively strengthened.

It is finally recommended that local education authorities in the region should consider what active steps may be taken to encourage the fuller use of libraries in teaching in technical and commercial colleges and that the teachers' organizations represented on the Regional Advisory Council should also be invited to give urgent consideration to this matter.

MANAGEMENT BY SUPERVISION

IN the world of industrial management it is becoming increasingly fashionable for lectures and articles to consist of exhortations or harangues by senior executives based on long experience in their particular firms. This, though useful, has its limitations, and it is refreshing to read a management journal where observations based upon original investigation are included. In the current issue of *Personnel Management* (38; September 1956), the organ of the Institute of Personnel Management, two articles describe researches which have been carried out by workers with experience in the field of social science. One of these, Nancy Wansborough, of the Acton Society Trust, has examined the effectiveness of internal advertising of vacancies as a means of making a demonstrably fairer system of promotion in industrial organizations. Her general conclusion is that the advantages of internal advertising outweigh the disadvantages, particularly in a firm where relations are already good. But in a firm where morale is low, employees may wonder whether advertisements are genuine or whether they are being used as a smoke-screen. In such circumstances, the introduction of advertising may make the last state worse than the first.

The second article has been contributed by Rensis Likert, director of the Institute of Social Research at the University of Michigan. Since 1947 the Institute has been conducting a series of related studies seeking to find what kinds of organizational structure and what principles and methods of leadership and management result in the highest productivity, least absence, lowest turnover, and the greatest job satisfaction. Studies have been conducted, or are under way, in a wide variety of organizations. These include one or more companies in such industries as the following: public utilities, insurance, automotive, railroad, electric appliances, heavy machinery, textiles and petroleum. Studies have also been made in government agencies.

In general, the design of the studies has been to measure and examine the kinds of leadership and related variables being used by the best units in the organization in contrast to those being used by the poorest.

When foremen are asked what they have found to be the best pattern of supervision to get results, a substantial proportion, usually a majority, will place primary emphasis on getting out production. Other supervisors, whom Likert calls employee-centred, report that they get the best results when they place primary emphasis on the human problems of their workers.

Higher levels of management, in discussing how they want their foremen to supervize, tend to place more emphasis on the production-centred approach as the best way to get results; workers, on the other hand, tend to place less.

But which orientation yields the best results? A variety of studies in widely different industries show that supervisors who are getting the best production, the best motivation and the highest levels of worker satisfaction are employee-centred appreciably more often that production-centred.

Related to orientation of supervision is closeness of supervision. Close supervision tends to be associated with lower productivity, and more general supervision with higher productivity. Low productivity at times leads to closer supervision; but it is clear also that it causes low productivity.

In one of the companies involved in the research programme it was found that switching managers of high- and low-production divisions resulted in the high-production managers raising the productivity of the low-production divisions faster than the former high-production divisions slipped under the low-production managers. Supervisors, as they were shifted from job to job, tended to carry with them and to maintain their habitual attitudes towards the supervisory process and towards their subordinates.

Investigations showed that the closer the supervision the less the productivity. Where supervision was more general, productivity increased, and this was accompanied by shifts in a favourable direction in attitudes, interests and perceptions. Workers became more interested and involved in their work, accepted more responsibility for getting the work done, and their attitudes towards the company and their superiors became more favourable; they accepted direction more willingly.

Where the supervision was close, all these attitudes and related variables shifted in an unfavourable direction. "All the hostilities, resentments, and unfavourable reactions which have been observed again and again to accompany extensive use of the scientific management approach manifested themselves." A fundamental conclusion from this experiment and similar research is that direct pressure from one's superior for production tends to be resented, while group pressure from one's colleagues is not.

Other experiments were concerned with the relationship between morale and productivity. It is generally believed by management that the higher the morale, the higher the production. Substantial research by Likert and others has shown that this relationship is much too simple. Some units have low morale and low production; other units have fairly good morale and low production; still others have fairly good production but low morale; finally other units have both high morale and high production.

Units with low morale and low production tend to have supervision which is *laissez-faire* in character and in which the leadership function has largely been abandoned. Units which have fairly good morale but poor production tend to have supervisor who try to keep people 'happy'. These supervisor are often found in companies in which human relations training programmes have been introduced and emphasized.

In the outstanding firms there is a kind of supervision which results in high production with high morale, high satisfactions and high motivation.

Making a plea for the rapid extension of research into management problems in industry and elsewhere, Likert insists that every research projec dealing with supervision and leadership show how the most able supervisors and managers ar struggling in company after company with trial-and-error methods to discover how to improve thei supervision.

It is possible to wait for this trial-and-error proces gradually to evolve and to make clear what the new organization and management theory and processe will be. It would be faster and much more efficien to use the power of systematic research and experiment to accelerate their discovery and refinement Those companies which support and co-operate i research to discover improved processes of management and to train their personnel will have a distinc advantage over companies which do not. Thos which support research will discover at an earlie date the principles and practices which the successfu companies of the future will be using and in whic their own developing executives and managers shoul be trained. They will not experience the traged and cost of obsolete management which is so commo in industry.

THE FATE OF WILHELM HIS

By DR. LAURENCE PICKEN

The Library, Zoological Station, Naples

> "The experience of many years has taught me that phrases oft repeated finally ossify to conviction and utterly dull the organs of intuitive perception".
>
> (GOETHE: "On the Intermaxillary Bone".)

IT is the fate of certain men of science to have made so great a mark on their century-distant generation that their names add lustre still to a bibliography, though their views (it is agreed), if not erroneous, are at least outmoded. Such names evoke a grateful sense of progress; they may be held up to the young as a warning against being unsound; and of corruption there is no danger—for who would read a discredited though venerable author? Th highly select company includes among others, and varying degrees of membership, Lamarck, St. Hilai and Ehrenberg; for many, Goethe; and unque tionably Wilhelm His, native of Basle, sometim professor of anatomy in the University of Leipzig.

The object of this article is to direct attention to th imperfect manner in which knowledge of the work His has been transmitted—an imperfection due that unmerited indifference, already well establish in his lifetime, of which Needham[1] has considered th historical causes.

"I can well remember", wrote Sir D'Arcy Thom son[2], p. 84, "the harsh criticism and even contem which His's doctrine met with, not merely on the ground that it was inadequate, but because such an explanation was deemed wholly inappropriate, and was utterly disavowed"; and His himself in his letter of 1888 to the Royal Society of Edinburgh[2] well summarized the types of reaction which his approach to embryological problems evoked. The aspect of his work which most offended was his contention (to quote Thompson[1] again, p. 83) "that the foldings of the blastoderm, by which the neural and amniotic folds are brought into being, were the resultant of unequal rates of growth in what to begin with was a uniform layer of embryonic tissue". Later critics have picked on the word 'growth' as vulnerable to attack, without pausing to inquire what His meant by that term; but his contemporaries were distressed by other and very different considerations. "To one it seemed ridiculous to speak of the elasticity of the germinal layers; another thought that, by such considerations, we 'put the cart before the horse'; and one more recent author states, that we have better things to do in embryology than to discuss tensions of germinal layers and similar questions, since all explanations must of necessity be of a phylogenetic nature. . . . The present fashion requires that even the smallest and most indifferent inquiry must be dressed in a phylogenetic costume, and whilst in former centuries authors professed to read in every natural detail some intention of the *creator mundi*, modern scientists have the aspiration to pick out from every occasional observation a fragment of the ancestral history of the living world"[2]. Again[2], "Embryology and morphology cannot proceed independently of all reference to the general laws of matter,—to the laws of physics and of mechanics. This proposition would, perhaps, seem indisputable to every natural philosopher; but in morphological schools, there are very few who are disposed to adopt it with all its consequences".

To his contemporaries His was known not only for his mechanical interpretation of certain facts of development, but also for his support of the theory of concrescence; in his own words[3], "The body of an osseous or an elasmobranch fish arises by the coalescence of two halves previously formed at the periphery of the germinal disk". But it escaped the notice of his contemporaries, as it has of posterity, that in the course of work on such embryos he had established, by measurements of areas of serial sections, that the volume of the germ of a salmon, for example, is practically the same as the volume of the fully formed embryo together with the yolk-membrane. "The embryo has been formed from the segmented germ without any increase in volume, only by displacement of its masses"[3].

It was, perhaps, in his views on the importance of measurement for the understanding of morphogenetic processes that His displayed the greatest originality; and it should not be forgotten that we owe to him the procedure of serial reconstruction. "The ways of determining the forms and volumes of germs and embryos are somewhat longer and more tiresome than the simple inspection of stained sections; but the general scientific methods of measuring, of weighing, or of determining volumes cannot be neglected in embryological work, if it is to have a solid foundation of facts, for morphologists have not the privilege of walking in easier or more direct paths than workers in other branches of natural science"[3].

For such views he was condemned; and as a result of that condemnation he was not read with attention by many of his contemporaries, and he is still not read by some of those who cite him. I have assembled here a few examples of conspicuously imperfect acquaintance with his views, and of the reactions of later generations to some of his ideas, associating them in each case with the actual content of his publications.

Morgan[5] re-examined the formation of the teleost embryo. His bibliography includes three works of His[6-8]; but rather surprisingly he does not include the papers on the development of bony fishes[4,9], contenting himself with His's summary re-statement of 1891[3]. In his paper of 1895, Morgan presents the results of measurements of cell-areas in the extra-embryonic blastoderm, made in order to determine whether the increase in area of individual cells could account for the increase in area of the extra-embryonic region. He had been anticipated in this type of approach by His[4], who already in 1878 had published measurements of area and volume of individual cells of the salmon germ at four stages of development; he had also measured thicknesses and calculated the volume of the germinal disk and of its various regions. Morgan sought evidence that the embryo becomes longer because it becomes narrower[5]: "If it could be shown that the amount of material present in the embryo [that is, initially present] is equal to the material of the fully formed embryo, there would remain no doubt that the elongation of the embryo was due to axial concentration". But His had shown in 1878 that between a length of 1·45 mm. and 4·3 mm. the volume of the embryo had increased from 0·279 mm.^{3} to 0·427 mm.^{3}, so that the increase in length could not be accounted for by axial concentration alone. Furthermore, His was aware of the point made by Morgan, that axial concentration may contribute to the elongation of the embryo backwards, for he gives in that same paper[4] measurements showing that the head elongates somewhat while narrowing—though in his paper of 1891[3], in emphasizing the appositional character of growth in length, he asserted the constancy of head-length. I do not quote His's views and figures believing them to be correct, but only to show his out-of-century approach, and the fact that someone of Morgan's stature, working in the same field, could afford to ignore those of his publications which one would have supposed most relevant.

Vandebroek, in his definitive memoir on morphogenetic movements in the embryogenesis of *Scyllium*[10], twice mentions His: first, as the originator of the theory of concrescence—which strictly speaking, as Morgan pointed out, he was not; the credit for the initial idea must go to Lereboullet. The reference given is to a one-page communication[11] to the Leipzig Natural Science Society, not to the definitive publication on shark development[7]. Secondly, reference is made to a statement by His[12] that the segmentation cavity and the archenteron are one and the same thing; there is no such statement in the paper cited. Vandebroek was presumably unaware that the pattern of surface-movement he had revealed by Vogt's method—though not the deeper gastrulation movement, of which His was ignorant—bears a striking resemblance to the pattern of postulated surface-*forces* illustrated by His[8] (Fig. 1 of that paper) and discussed at length in his paper of 1894[13]. (See in particular Vandebroek's Fig. 32.) Although the theory of concrescence as formulated by His rested on an inadequate analysis of the kinematics of fish-development, it contained a flash of insight from which later views profited. Since Vandebroek's analysis it is evident that, although not in the manner envisaged by His, a great part of the material of the embryo has at some time formed part of the margin of the germinal disk; and imperfect though the formulation was, the conception of His helped to prepare the way for the view of development as a translocation of cells.

In that wonderfully organized book[14], "Principles of Development", Weiss refers to His; once, as the originator of a term 'organ-forming areas'[6]—forerunner of 'presumptive areas'; and again, for the fact that among authors who were "exclusive in the choice of agents they believed to be involved" in nerve development, His "favored a mechanical interpretation". Such a judgment is somewhat harsh and leaves the reader with no hint of the balance which His displayed, nor of the extent to which he anticipated certain of Weiss's own views. "The sensory process of a sensory nerve fiber", wrote Weiss[14] ". . . grows more or less perpendicularly into the dorsal portion of the spinal cord; there it splits into two branches which take a lengthwise course. . . . Although there is no direct proof of it, the assumption is obvious that both the bifurcation and the deflection of these fibers is the result of one and the same condition, namely, the fact that at their entrance into the cord they strike upon the longitudinal structure of the dorsal columns of the spinal cord . . . branching may be considered as a peculiar by-product of the deflection of fibers obtaining under certain conditions".

"The longitudinal deflection of the sensory roots at the surface of the spinal cord and brain", wrote His[15], "can be referred to the fact that fibres reaching this position are unable to continue their advance in the same direction. In the interior of the cord, the spongiosa forms a system of passages which determine the manner of distribution of the intramedullary fibres. . . . Branching itself may be interpreted as a consequence of continued growth of the individual processes against a resistance". Weiss makes amends, however, in a recent review[16] where he refers to his own ideas on 'contact-guidance' as "but a modification and more detailed version of such concepts of nerve orientation as have been proposed by His" and others.

The nature of His's 'mechanistic' outlook is clearly conveyed by the following passage[15]: "If the course of the developing nervous paths is determined now by trabeculae of the spongiosa, now by cartilage or blood-vessels, it may at first sight appear questionable that such chance occurrences should intervene in the development of a system which controls our entire life—body and soul. The problem takes on another aspect, however, when we realize that this is a developmental process, the course of which is predetermined in the act of generation. The totality of partial processes must interact with each other in a strictly ordered manner, once the process is initiated; for—in Leibniz's beautiful phrase—the harmony of organic development is a 'pre-established harmony' ".

Pasteels, in his revolutionary review of gastrulation in the chordates[17], gives as the first source relating to His's conception of concrescence his monograph on oogenesis and egg-structure in bony fishes[18] in which there is no reference to concrescence. Like Vandebroek, he overlooks the significance of His's interpretation of folding in terms of surface movements.

As a last instance of injustice, though from a generous critic, Holtfreter, in the first of his papers on the mechanics of gastrulation[19], wrote: "W. His (1874) in his pioneer work on the causative factors of morphogenesis envisaged foldings, invaginations and epibolic expansions as growth phenomena, picturing them as a result of increased cell multiplication of certain predetermined areas, and an interplay of mechanical forces between the regions of differential growth. . . . Actually, cell divisions in amphibian eggs up to the neurula stage simply reduce the cell size but lead to no increase of the egg substance". This comment is repeated in Townes and Holtfreter[20].

Unfortunately for His, it has escaped the notice of many of his later critics that already in 1878 he had changed his position from that maintained in the monograph on chick-development[21] and in the "Letters to a Scientific Friend: Our Bodily Shape and the Physiological Problem of its Origin"[6]. As a result of further studies on chick- and teleost-development, he had reached the conclusion that it is necessary to distinguish, "much more sharply than I and other investigators have done hitherto, between surface-growth and mass-growth. . . . The thinnest regions are those of most rapid surface-growth"[4]. He continues: "As my last work has confirmed for the chick-embryo[22] also, a surface-expansion occurs independently of mass-growth . . . and it will be for the future to determine how far the one or the other determines the shapes generated". He then proceeds to consider the possible influence of cell division as a contributory factor in surface growth: "In the mere parcelling-out of a mass of material there is no reason for the shape of the mass to change; it is necessary to make a subsidiary hypothesis: that cleavage always proceeds in the same direction, so that the fragments of all the elements belonging to a layer come to lie beside one another. In this way, surface-increase without mass-increase is certainly possible. . . . We may grant the possibility of this explanation, leaving on one side for the moment the question: why this surface division occurs, and ignoring the fact that in the course of development the cells show other than spherical shapes—at times radially extended, at times flattened; but when we face the fact that not only do the layers become thinner, but the number of superimposed cells in them diminishes over a certain period, this explanation becomes untenable . . ."[4].

Holtfreter supposes (and he is not alone in this) that His believed cell-division to be the driving force of his foldings; but clearly by 1878 His held no such view.

"As things are at present, it is impossible to escape from the idea of active cell-participation in attempting to explain the moulding of the embryo; but this is not to be thought of in terms of veritable mass-migrations, but rather as processes of a more local character. . . . The situation can best be accounted for, if one ascribes to the cells a tendency to migrate to the surface in maximum possible extension. Where the layer is thick, underlying cells penetrate between the superficial cells and separate them because of this tendency; where the layer is thin, however, the cells spread themselves out, so that they acquire the largest possible free surface"[4]. How far this view of the importance of individual cell behaviour, and of surface-spreading, in morphogenesis coincides with that of Holtfreter himself it is unnecessary to emphasize.

The most penetrating and just contemporary critic of His was Roux[23], who showed experimentally that the rolling of the neural tube continues after its isolation (by incisions) from the postulated thrust of the surrounding tissue. On this work of Roux's His commented in 1894[13], and in the course of his commentary goes far beyond Roux's recognition of the intrinsic capacity of the medullary plate to fold, anticipating Rhumbler, Moore and Lewis: "Suppose we have a sheet of cells, the elements of which are as wide at their bases as they are at the free surface. If now, as a result of internal forces, the cells are all induced to become thicker at their bases and thinner at their free ends, the result will be that the sheet bends and folds together to form a hollow structure". His goes on to say that he personally favours the view that there is an interaction of external pressure and internal developmental processes—such as those responsible for the change in shape of the individual cells just described.

It is a pleasure to be able to mention at least one modern critic who has done justice to His, namely, Oppenheimer[24], though her comments are restricted to the contents of "Unsere Körperform"[6].

I have assembled these passages not merely in order to direct attention to what appears to me to be a singularly flagrant historical injustice, but also in the hope that some embryologist, and preferably some countryman of His's, with full patience for his leisurely manner and antiquated anatomical and histological views and vocabulary, may be stimulated to examine his total output—which is not large—and to make a critical assessment of his work in the light of modern developments in embryology. I have the impression that between the study of induction, the mapping of presumptive areas and the analysis of prospective fates and cell-properties, something has been lost sight of to which His directed attention in 1888: "The germinal layers are elastic plates under the influence of certain pressures . . ."[3]; mechanical properties cannot be indefinitely neglected.

The quotation heading this note was used by His as motto for his own life-work summary[13], published in 1894, ten years before his death. It applies as well to his personal experience as it did to that of Goethe when, in his thirties, he sought to convince Camper of the presence of the intermaxillary bone in man as in apes.

PARTITION OF SULPHONAMIDES IN PLANT ROOTS: A FACTOR IN THEIR TRANSLOCATION

By Dr. S. H. CROWDY and Dr. D. RUDD JONES

Imperial Chemical Industries, Ltd., Jealott's Hill Research Station, Bracknell, Berks

In an earlier paper[1], data were presented on the movement of seven sulphonamides through broad bean plants which had been grown in water culture containing 100 µgm./ml. of a sulphonamide. There was appreciable accumulation of the sulphonamides in the roots, and this was specific for a particular compound. Once a compound had left the root system it was possible to postulate movement in the transpiration stream. To reach the vascular system of the plant, a compound must enter the root tissues and move across the living cells of the cortex.

In the course of the translocation studies, the individual compounds were identified in tissue extracts on paper chromatograms, and it became apparent that there was a general relationship between the rate at which the compound moved in the plant and the R_F value on the chromatogram. This suggested a comparison between movement across the root and movement on filter paper, both of which may be attributed to a partition mechanism.

In addition to the data already published[1], comparable uptake and translocation studies have been made with four additional compounds: two of the sulphonamide type, 2-(*p*-aminobenzenesulphonamido)-4 : 6-dimethylpyrimidine ('Sulphamezathine') and 4-acetamidobenzenesulphonamide, the N^4 acetyl derivative of sulphanilamide; and *p*-aminobenzoic acid and sulphanilic acid, both of which can be determined with the same assay used for the sulphonamides.

The separation of these compounds on paper chromatograms has been followed using *n*-butanol–acetic acid–water, *n*-butanol–ammonia–water and chloroform–ethanol–ammonia–water solvent systems. The proportion of ethanol in the last system was varied to alter the amount of water in the mobile phase. Chromatograms were developed on Whatman No. 1 papers and spots were located by diazotization and coupling[2]. In all systems the organic solvent mixtures were the mobile phase; there was no distinctive separation of these compounds using a mobile aqueous phase on lipoid-treated papers or olive oil as a mobile lipoid phase. In an attempt to simulate conditions which might occur in the plant, the

Table 1. THE EFFECT OF VARIOUS SOLVENT SYSTEMS ON THE RATIO OF SHOOT ACCUMULATION RATE IN BROAD BEANS TO R_F VALUE FOR SULPHONAMIDE-TYPE COMPOUNDS

5	„ „ „ „ (4–4–1–3)
6	Chloroform–ethanol–buffer solution (4–2–4) 0·5 *M* KH_2PO_4/NaOH initial *p*H 7·8, final *p*H 7·0

volatile components acetic acid and ammonia were replaced by buffering papers and solvent systems at *p*H 7·8 with 0·5 *M* phosphate buffer. The final *p*H on the papers after development was *p*H 7·0, which is close to the determinations of *p*H made on expressed root sap with a glass electrode (*p*H 6·3–6·8).

In presenting the results of these experiments in Table 1, the model system visualized is essentially a partition chromatogram in which the transpiration water containing the compound under test and other compounds accumulated during passage across the root is continuously partitioned on a column made up of root tissue. It has been shown previously[1] that the early stages of treatment, before the tissues become saturated, are characterized by a constant relation between uptake and transpiration. During this period the amount of compound accumulated in the shoots is directly proportional to the amount of water transpired. Thus the shoot accumulation-rate is essentially a measure of the concentration of the treating compound in the transpiration stream. The concentration of the treating solution was the same in each case (100 µgm./ml.), so that the shoot-rate provides a measure of the partition in the root tissues. If comparable conditions for partition can be established on the paper chromatograms, the ratio of the shoot-rate to the R_F value will be constant for a number of compounds, and Table 1 illustrates an attempt to reproduce these conditions. In this table only the ratios have been included, but the R_F values can be calculated from the appropriate shoot-rates. High ratios indicate poor movement on the chromatograms, and ∞ no movement.

Two main effects have been studied in the experiments illustrated—*p*H and lipoid solubility. The movement of a neutral compound reasonably soluble in both water and lipoids should be little affected by changes in conditions and should, therefore, give rise to a constant ratio in all the systems used. Further, if this constant can be applied to a number of compounds the figure should be generally applicable. The sulphone is a compound which fulfils the required conditions, and it seems that 40–45 : 1 should be the ratio aimed at. Other compounds which might move as the sulphone would be the neutral N^4 acetyl sulphanilamide, sulphaguanidine and possibly sulphanilamide which has a high *pKa* and will, therefore, be largely undissociated under the conditions studied. However, lipoid solubility is also a controlling factor, and sulphanilamide and its N^4 acetyl derivative only move on chromatograms when there is an appreciable aqueous component in the mobile phase. Sulphaguanidine moves readily in systems with a high aqueous content in the mobile phase; but its mobility is reduced with water content and it is possible to devise systems in which the mobility gives the characteristic ratio of the sulphone. The assumption is that with neutral compounds and compounds with a high *pKa*, movement is concerned mainly with the undissociated molecule.

Table 1 contains a further group of compounds which are likely to be in the same state on the chromatogram as they are in plants. These are compounds with a low *pKa* value which are probably highly dissociated in both, namely, *p*-aminobenzoic acid, sulphanilic acid and possibly sulphacetamide. They travel more rapidly in the acetic acid system but give fairly constant ratios in the more alkaline systems, suggesting that in the plant it is the ion that is moving, and this may account for the poor mobility as indicated by the low shoot accumulation-rates. *p*-Aminobenzoic acid provides an anomalous case, and its translocation differs from the other compounds in that there is a very high uptake into the roots and a very low transfer to the shoot.

The remaining four compounds, sulphadiazine, sulphathiazole, sulphapyridine and sulphamezathine, have *pKa* values which lie critically close to those on the papers and probably to those in the plant. Small discrepancies in *p*H might, therefore, be expected to make large differences in the proportion of undissociated molecules present in either system. On the chromatograms, as would be expected, they move more readily when undissociated under acid conditions. With a suitable buffer it has been possible to a great extent to correct the movement of sulphadiazine. The binding of these compounds to proteins has been reported in certain animals[4,5] and it seems likely that the ions are concerned in this binding. Binding of this type may also account for their abnormally low rate of movement in the plant. It has been possible to reduce the R_F values on papers sprayed with albumin, as is shown in Table 2; but the retardation has not been sufficient to give a satisfactory ratio. This is not surprising since the degree of binding will probably depend on the physical state of the protein and the *p*H of the system. Hydrogen bonds and van der Waals' forces may also be involved and their effect will vary with the different compounds.

Further evidence on protein binding was derived from differential extraction of roots of treated broad beans. A large proportion of the sulphathiazole,

Table 2. R_F VALUES OF SULPHONAMIDE-TYPE COMPOUNDS IN AN *n*-BUTANOL–AMMONIA–WATER (4–1–5) SOLVENT SYSTEM ON NORMAL AND PROTEIN-TREATED PAPERS
(10 per cent solution of bovine plasma albumin, Fraction V; Armour Laboratories)

	R_F values Normal paper	Protein-treated paper	Per cent retardation of R_F
4 : 4′-Diaminodiphenyl sulphone	0·87	0·76	12 6
Sulphanilamide	0·57	0·49	14·0
N^4 acetyl sulphanilamide	0·79	0·71	10·1
Sulphadiazine	0·24	0·18	25·0
Sulphathiazole	0·48	0·33	31·2
Sulphapyridine	0·52	0·40	23·1
Sulphamezathine	0·48	0·36	25·0

sulphapyridine and sulphamezathine taken in by the plant was retained in the roots and could not be removed by prolonged washing of root macerates with water and chloroform.

It would thus appear to be possible to adjust the conditions on a chromatogram to show a constant relationship between R_F and movement in the roots of broad beans. The required conditions, which have apparently been achieved for eight of the eleven compounds studied in the system shown in column 6 of Table 1, are a mobile lipoid solvent with a relatively high water content and a pH of the order of 6·8–7·0. The same effect would be produced if the lipoid component was retained on the stationary phase or moved more slowly than the aqueous component. The conditions illustrated in the model system might well exist in the plant since a stream of water passing through the root tissue could accumulate substances such as lipoproteins which would confer a lipoid solubility on the mobile phase, and pH values of root sap are of the right order. The retention of sulphathiazole, sulphapyridine and sulphamezathine in the roots, which is thought to be due to protein binding, has not been reproduced adequately in the model; this can perhaps only be done effectively by using protein material from the roots.

The evidence here presented indicates that most, if not all, of the movement of these compounds through root tissue may be attributed to physical rather than to specific biological processes. Further evidence supporting this conclusion is provided by the observation that the rate of accumulation of griseofulvin in the shoot is unaffected by 2,4-dinitrophenol and sodium azide[6], and the accumulation of sulphanilamide in the shoot is also unaffected by sodium azide[1]. Hylmö[7] claims that the movement of calcium and chloride ions associated with transpiration is unaffected by low temperature, which points to the same conclusion.

Partition will probably play a major part in a physical system of this type and the data presented above suggest a way of assessing its influence.

We are grateful to Mrs. A. Borrow and Mr. B. Langford for technical assistance.

A RARE VARIETY OF THE HUMAN BLOOD GROUP B

By I. DUNSFORD and S. M. STACEY
National Blood Transfusion Service, Sheffield
AND
M. YOKOYAMA
University of Tokyo

IN the blood of adults and children over the age of six months the serum always contains the agglutinin, or agglutinins, corresponding to whichever of the A or B antigens is lacking from the red cells. This was originally enunciated by Landsteiner[1], and many extensive series of tests have been made without the discovery of exceptions. Apparent exceptions to this rule are very rare, and on thorough investigation are usually shown to have feeble antibodies demonstrable only at low temperatures[2]. Recently, a sample of blood from a Japanese male, Mr. K., was investigated which at first appeared to be a true violation of Landsteiner's Law, but subsequent investigations show it to be possibly a rare variety of the human blood group B.

Serological studies :

(1) Routine ABO grouping by a tube technique[3].

	Anti-A	Anti-B	Group O (anti-AB)
Mr. K's cells	—	—	

	A_1 cells	A_2 cells	B cells	O cells	Own cells
Mr. K's serum	*V*	*V*	—	—	—

(2) The cells remained unagglutinated by eight selected high-titre anti-B (group A) sera at 4°, 18° and 37° C.

(3) The cells were not agglutinated by selected high-titre rabbit immune anti-A and anti-B sera.

(4) The cells were not agglutinated by ten selected high-titre group O (anti-AB) sera at 4°, 18° and 37° C., in saline, albumin or anti-human globulin techniques.

(5) The serum gave no reaction with a series of fresh group B cells suspended in saline at 4° C.

(6) There was no evidence of incomplete anti-B in the serum, demonstrable by the anti-globulin test or by albumin.

As we had previously found a group A person completely lacking in anti-B agglutinins and who was shown to be suffering from agammaglobulinæmia, an anti-globulin inhibition test was carried out on Mr. K's serum. The gamma globulin concentration[4] in his serum was normal, or slightly above normal. Having excluded agammaglobulinæmia, we now felt that this was possibly a true violation of Landsteiner's Law and that Mr. K's blood was thus $O\alpha -$.

(7) Based on some observations made on the human blood group chimera[5], which will form the subject of a separate communication[6], we then examined the ability of the person's serum to inhibit anti-A (group B) and anti-B (group A) sera. The results obtained are given in Table 1. This demonstrates the presence of B substance in Mr. K's serum.

(8) The amount of B substance present in the serum was compared with the sera from nine group B donors. This was estimated by mixing serial dilutions of each serum with a standard (1/10) dilution of anti-B (group A) serum, leaving the mixture at 20° C. for 1 hr. and then adding 1 volume of a 2 per cent suspension of B cells in saline. The results (Table 2) show that B substance was present in the serum in moderate amounts as compared with the nine group B donor sera.

(9) Mr. K's serum gave no reactions at 4°, 18° or 37° C. with known A_4 cells[7], suggesting that the serum was not from a group O person.

By the time the investigations reported here were complete, Wiener and Gordon's report[8] was just published of a blood, the red cells of which grouped as O—β, yet the saliva of this person contained A substance. They claim this as a further sub-group of A and propose the name A_m because of serological similarities between the blood they describe and the bloods of certain monkeys[9]. No claim is made that the blood reported here is a new sub-group of B, although indeed it may be. This part of the investigation awaits specimens (blood and saliva) from the relatives of the propositus.

Other possibilities that have to be considered are that this blood is a further example of the type described by Levine *et al.*[10] which was phenotypically *O*, but was proved to be of genotype *BO*, but the gene *B* was suppressed. However, while further investigation is necessary, one major difference between the blood described by Levine *et al.* and the blood here reported is that the former contained anti-H, whereas the blood we have examined did not possess such an antibody. Unfortunately, we did not test Mr. K's cells with anti-H.

An alternative possibility is that this blood is a defective B type in which the alcohol-soluble form of the antigen is lacking while the water-soluble form has developed normally. The defect may conceivably have resulted from the absence of normal complementary genes for the development of the alcohol-soluble antigen system, or from the influence of a modifying gene upon the alcohol-soluble system. This was suggested by Gammelgaard[11] to describe a blood A_x, which had little or no evidence of the A antigen in the red cells and yet the saliva was rich in A substance. Indeed, Gammelgaard's A_x and Wiener's A_m may be identical, and the latter may not be a new form of blood group A as claimed by Wiener.

The blood reported here is not an exception to Landsteiner's Law, providing the presence of the antigens is not confined to the red cells. In further work on the human chimera which will be reported later[6], we have observed that the chimera, although phenotypically *O—A*, possesses no anti-A agglutinins, but possesses A substances in her serum when not pregnant. However, when pregnant her serum possesses no A substances—even though she has A cells in her circulation—and at this time possesses an anti-A agglutinin. It would appear from the observations made on the present blood and on that of the human chimera that the presence or absence of agglutinins in the serum is more dependent upon group-specific substances in the serum than on the group-specific substances in the red cells.

It is hoped to carry out further studies on this blood and on that of members of this person's family, and to give a fuller report elsewhere.

We wish to thank Dr. A. E. Mourant, of the Medical Research Council Blood Group Reference Laboratory, London, for his suggestions.

Note added in proof. Since submitting this report for publication, members of Mr. K's family have been tested and his father and one sister have the identical variety of blood group B.

'LIVING' POLYMERS

By Prof. M. SZWARC

Chemistry Department, State University of New York, College of Forestry, Syracuse 10, New York

POLYMERIC molecules are born in an initiation process, they grow by a propagation process, and finally they 'die' in a termination process. This death is regulated by the conditions prevailing in the polymerization process, and thus, the rate of death, the average molecular weight of the polymer formed, and its molecular weight distribution are all well-determined functions of experimental conditions.

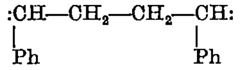
An interesting situation arises when a polymerization process does not involve a termination step. The polymeric molecules then 'live' for an indefinite period of time, and such a system should be profitable in many investigations. A 'living' polymer does not grow indefinitely, nor does its molecular weight increase beyond certain limits. Any growth requires food, and the food for a growing polymer is the monomer. Consequently, if the supply of monomer is exhausted the growth is interrupted, although the living ends are potentially able to grow further if an additional amount of monomer is available.

The exclusion of natural death does not mean immortality either. Reagents may be visualized which convert a living end into an unreactive dead end. Treatment of living polymers with such reagents represents, therefore, a killing process. The difference between the normal termination process—described here as a natural death—and the killing process lies in the unavoidable character of the former reaction, whereas the latter takes place at the time chosen freely by the experimenter. The advantage of such a termination is obvious.

Recently we have succeeded in preparing in our laboratories living polymers by carrying out an anionic polymerization in a non-acidic solvent, such as, for example, tetrahydrofurane. The growing end of an anionic polymer is a carbanion. If the polymerization is proceeding in a solvent which is a proton donor, then the transfer of a proton from the acidic solvent to the carbanionic end of a growing polymer terminates the polymerization. Such a mechanism operates, for example, in polymerization initiated by sodium and carried out in liquid ammonia. However, this termination is impossible in tetrahydrofurane solution.

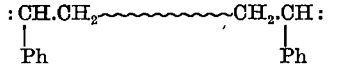
In solvents which solvate poorly the ions formed, the termination may occur by returning an electron from a carbanion to the cation (say Na^+). Such a reaction probably terminates the polymerization initiated by sodium in hydrocarbon solution. However, tetrahydrofurane solvates the ions well, and therefore in this solvent the re-formation of neutral species is energetically unprofitable. Hence, this second termination mechanism does not operate in tetrahydrofurane either.

One assumes finally that the anionic polymerization carried out in tetrahydrofurane solution does not involve any termination step, and in order to examine this assumption the following experiments were carried out with styrene as the monomer. The polymerization was initiated by the intensely green complex naphthalene anion, sodium cation. This initiating catalyst was discovered by Scott[1] and the mechanism of this initiation was elucidated recently in our laboratories[2]; we showed that it involves an electron transfer process from the naphthalene anion to the monomer, for example, styrene. Consequently, negative monomer ions are formed which eventually dimerize into species such as:



$$:\underset{\mathrm{Ph}}{\mathrm{CH}}\text{—}CH_2\text{—}CH_2\text{—}\underset{\mathrm{Ph}}{\mathrm{CH}}:$$

and the latter grow by a carbanionic mechanism until the monomer supply is exhausted. Thus, living polymers of the following structure are formed:



$$:\underset{\mathrm{Ph}}{\mathrm{CH}}.CH_2\sim\sim\sim\sim\sim\sim\sim\sim\sim\sim CH_2.\underset{\mathrm{Ph}}{\mathrm{CH}}:$$

The —Ph.CH: ends of the living polymers are bright red—this is essentially the colour of the negative benzyl ions. Hence, the green colour of the catalyst solution (naphthalene anion) turns red instantaneously when introduced to the styrene solution. In absence of air or moisture the red colour persists for days, without any apparent change of intensity. However, when air or moisture comes in contact with the solution, the red colour disappears —the living ends are killed; for example:

$$\sim\sim\sim\sim\sim\sim Ph.CH:+H_2O \longrightarrow \sim\sim\sim\sim\sim\sim Ph.CH_2+OH^-$$

Hence, the observation of colour is the simplest manifestation of living polymers.

At this juncture one may wonder whether an electron located on a carbanionic end of the polymer may be transferred to the naphthalene molecule. Such a process would be easily recognized. The anionic ends deprived of an electron are transformed into radical ends. The latter undergo an irreversible dimerization process. Consequently, the final result would be the change of the colour from red to green, and an increase in the viscosity of the solution resulting from polymerization of polymers. Neither of these effects was observed, showing that the proposed electron transfer is too slow to be seen. This result reflects, of course, the much higher electron affinity of benzyl radical as compared with, say, naphthalene.

Now, if additional amounts of styrene and of tetrahydrofurane are added to the red solution of a living polymer, further polymerization ensues. If the ratio of styrene to solvent is chosen to be identical to that in the first batch, then the *concentration* of polystyrene formed remains unaltered by the second polymerization. Nevertheless, the viscosity of the solution increases enormously. This increase in viscosity, coupled with the fact that both portions of styrene are converted quantitatively into a polymer, proves that the second batch of monomer polymerized on the living ends of the previously prepared polymer.

This experiment suggests an interesting and novel method for the preparation of block polymers. After completion of the first polymerization process, a second monomer is added to the still living polymers formed from the first monomer. Thus, block polymers of the type *AA...A.B.B...B.A.A...A* are produced. For example, polymerization was initiated in styrene solution. When the reaction was ended, isoprene was added and further polymerization ensued. After killing with water, a polymer was obtained which was shown to contain neither polystyrene nor polyisoprene. Thus, the nature of the block polymer is established.

It is interesting to compare the effect of two killing agents, namely, water and oxygen. If the viscosity of the red solution of living polymers is determined and then a drop of water is introduced, the colour will disappear but the viscosity of the solution remains unaltered. This killing process leads to a transfer of a proton from a water molecule to the carbanionic end of the living polymer, and such a process is not expected to change the molecular weight of the polymer. On the other hand, if oxygen is introduced into the red solution, the colour disappears again, but simultaneously with this effect the viscosity of the solution increases considerably.

It is believed that oxygen represents the class of killing reagents which removes one electron from the carbanionic ends. The high electron affinity of the oxygen molecule favours this reaction:

$$\sim\sim\sim CH_2.Ph.CH:+O_2 \longrightarrow \sim\sim\sim\text{—}CH_2.Ph.CH\cdot+O_2^-$$

Consequently, the living ends are transformed into radicals, and the latter undergo dimerization. (It is possible that the dimerization process involves oxygen bridges due to the action of other oxygen molecules. This, however, does not change the essential characteristic features of the phenomena described here.) Since our living polymers possess two living ends, the dimerization process leads to polymerization of polymers, and consequently, to a considerable increase in the viscosity of the solution.

I hope that these brief comments will show how versatile is the chemistry of living polymers. A detailed description of this work will be published later.

Optical Rotation of the α-Helix in Synthetic Polypeptides

In a communication from this laboratory[1], the belief has been put forward that the polypeptide chains in poly-L-alanine fibres form right-handed rather than left-handed helices; this view is based on the X-ray diffraction pattern. If it is correct, it is to be expected that the same sense of helix will be the stable form in other L-polypeptides. Now the contribution to the optical rotation of an α-polypeptide from the helix alone is considerable; according to Fitts and Kirkwood[2], a right-handed helix of polyglycine should have a specific rotation of about + 130°. In a later communication[3] they have concluded from the change in specific rotation on destruction of the α-helix (in poly-γ-benzyl-L-glutamate and in poly-L-glutamic acid) that in these polymers the helices are right-handed.

The stability and sense of the α-helix can be examined by measuring the optical rotation of a series of polypeptides in which the proportion of D- to L-residues is varied. The addition of a proportion of D-residues, randomly arranged along a chain of L-residues in the α-helix form, will not affect the helix if this has a strongly preferred sense. The optical rotation of a predominantly L-polypeptide should therefore at first move towards higher positive values as the proportion of D-residues is increased, but must ultimately become zero when D- and L- residues are present in equal amounts.

We have measured the optical rotation of a series of D : L-leucine polypeptides in benzene at a concentration of 0·2 per cent (w/v). Films cast from these solutions showed the carbonyl infra-red absorption band in the normal position for the α-form. Since many of these polymers form gels under these conditions (even at 60° C.), small amounts of *m*-cresol (minimum 1 per cent, v/v) were added, and the optical rotation in pure benzene was obtained by extrapolation to zero concentration of *m*-cresol. This procedure was justified by measurements made in pure benzene, when the solubility allowed this. The addition of *m*-cresol lowers the positive rotation of the mainly L-polypeptides. Even with *m*-cresol present, it was found necessary to make measurements at 60° C. to avoid gel formation. It is convenient to express the results in terms of the residue rotation $[R]$

$$[R] = \frac{R}{100}[\alpha]$$

where R is the residue weight and $[\alpha]$ the specific rotation defined in the usual way. The results are shown in Fig. 1.

The expected effect is strikingly apparent, and the increase in rotatory power continues to a lower excess of L over D values than might have been anticipated. The increase in rotatory power is not caused by increasing instability of the α-helix as the proportion of D-residues becomes greater (leading to the formation of a random coil), because conditions which favour a random coil lower the positive rotation[4]. The linear part of the graph is readily accounted for if, over this range, all the polypeptide chains are right-handed, producing a positive rotation from the helix core, with the L- and D-side-chains giving respectively negative and positive contributions. The contribution from the helix core is given by the intercept on the *y*-axis, and corresponds to a residue rotation of + 138°. We may note that the corresponding value for poly-L-leucine in benzene calculated from Fitts and Kirkwood's formula is 70°.

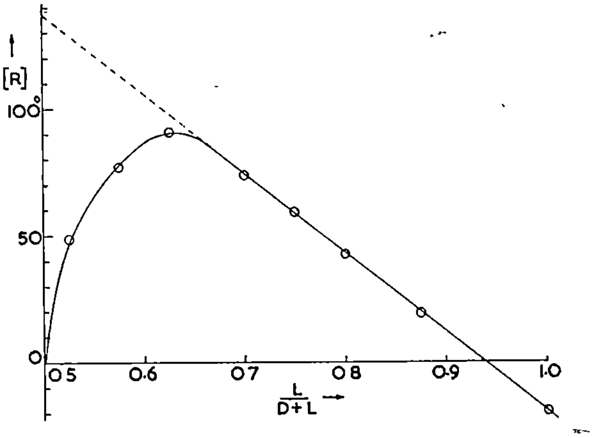

Fig. 1. Residue rotation of poly-leucine plotted against fraction of L-residues in polymer. Concentration 0.2 per cent w/v in benzene at 60° C.; λ = 5893 A.

Our experiments show clearly that, in solution, one sense of helix is significantly more stable than the other for a given enantiomorph. Together with Fitts and Kirkwood's calculation that the form optical rotation is positive for a right-handed helix, the results confirm that L-polypeptides form right-handed helices. The possibility that the optical rotation of an α-polypeptide can be treated as the sum of contributions from the helix core and the asymmetric centres is interesting, and may have applications in the case of proteins such as silks.

Blood-Group Antigens on Human Epidermal Cells

Recently, Coombs, Bedford and Rouillard[1] reported that the A and B blood-group antigens are present on human epidermal cells. A series of skin samples has now been examined for blood-group antigens other than A and B by the method of mixed erythrocyte-epidermal cell agglutination described by these authors.

Suspensions of isolated epidermal cells were prepared by treating small fragments of stored, thin

Table 1. SERA AND NUMBERS OF SKIN SAMPLES TESTED

Blood group system	Sera (heat inactivated)	Titre of sera against red cells	No. of skin samples tested
Rh	anti-D (Pe)	128–256	8
	anti-D (Ba)	320	7
	anti-D (Wo)	2,000	1
	anti-C (Mi)	32–64	5
	anti-c (Ha)	256	5
	anti-E (Du)	128–256	2
MN	anti-M (Sh 1,325 human)	64–128	1
	anti-M (184 rabbit)	256	1
	anti-M (195 rabbit)	256	4
	anti-N (203 rabbit)	4–8	1
	anti-N (205 rabbit)	32	7

	anti-Le^{b} (Ba)	2	2
Lutheran	anti-Lu^{b} (Ro)	4–8	3
P	anti-P (Fl. human)	8–16	2
	anti-Tj^{a} (Pa)	32	3

split skin with crude trypsin[2]. The irregular shapes of the cells in these suspensions make direct agglutination tests unsuitable, and sufficiently large quantities of cells are not easily obtained for absorption tests.

In the tests, the cell suspensions were exposed to an equal volume of a specific grouping serum; the antigen corresponding to this serum was known to be on the skin donor's red cells. After washing to remove uncombined antibody, the epidermal cells were mixed with a 0·5 per cent suspension of red cells possessing the appropriate antigen, and the mixture was centrifuged gently to bring the cells into contact. In this way it was possible to detect the A antigen on epidermal cells, because anti-A formed a specific link between epidermal cells from group A donors and A red cells. No link was formed with B or O red cells. The agglutination is dependent on the theory that antibody molecules are bi- or multivalent, that is, that they have at least two receptors capable of combining with the antigen; in this instance, the antibody receptors combine with an antigen on an epidermal cell and another on a red cell. But, using Rh, MN, Lewis, Lutheran and P antisera and a number of skin samples, as shown in Table 1, it was not possible to demonstrate the presence of the corresponding antigens by means of mixed agglutination.

It should be mentioned that all the skin samples had been exposed to 0·5 per cent crude trypsin solution for one hour, since certain brands of trypsin are reported to be capable of destroying the M and N antigens on red cells[3]. Also, some of the sera available, especially anti-Le^{a} and anti-Le^{b}, were very weak.

Epidermal cell antigens are thought to be concerned in the immunological response to skin homografts; but the evidence suggests that the blood-group antigens may be of little or no importance, since in rabbits, previous injection with red cells failed to affect the response to skin grafts[4]. The inability to detect blood-group antigens, other than A and B, on human epidermal cells strongly suggests that even if surface antigens are involved in the homograft reaction in man, then iso-antigens, other than those common to red blood cells, must be responsible. The recent work of Billingham, Brent and Medawar[5] points to nuclear substances as the source of the antigenic stimulus.

We wish to thank Drs. I. Dunsford, P. L. Mollison, A. E. Mourant, R. R. Race and C. B. V. Walker for the grouping sera used in this work. Also, we would like to record our appreciation to Sister M. J. Davies and the staff of the Ear, Nose and Throat Theatre, Addenbrooke's Hospital, Cambridge, for their most helpful co-operation at all times.

The work was aided by a grant from the Nuffield Foundation and the Agricultural Research Council.

Some Nitrogen-containing Disaccharides isolated from Human Blood-Group A Substance

IN an attempt to learn more of the detailed chemical structure of human blood-group substances and of the relationship of structure to serological specificity, the products of partial acid hydrolysis of these important biological materials are being examined. Preliminary observations on the isolation of five nitrogen-containing disaccharides from group A substance are reported here.

Human blood-group A substance (15 gm. nitrogen 5·4 per cent, fucose 20 per cent, hexosamine 35 per cent, electrophoretically homogeneous at *p*H 8) was prepared from ovarian cyst fluid (No. 203)[1]. The material was divided and heated as 1 per cent w/v solution at 100° in (*a*) 0·1 *N* hydrochloric acid for 3 hr. and (*b*) *N* hydrochloric acid for 30 min. The acid was removed by treatment with 'Deacidite *E*', the solution concentrated and passed through a charcoal - 'Celite' (1 : 1) column using water and water–ethanol mixtures as eluants. The individual fractions were examined by paper chromatography and the substances present distinguished by R_F values and colour reactions with various spray reagents. The fractions containing disaccharides with closely similar properties were combined and passed through cellulose columns using amyl alcohol/dioxan/water (15 : 3 : 2) as eluant. Homogeneity of the effluent was checked by paper chromatography using mainly butanol/pyridine/water (3 : 1 : 1) as solvent. The individual sugars of the disaccharide units were identified by chromatography after hydrolysis with acid.

Of the disaccharides liberated by the partial hydrolysis of A substance, the following nitrogen-containing materials have been recovered and in two instances completely identified with substances of known structure. The structure of the remaining three disaccharides is not yet fully established.

Disaccharide (1) was identical with the O-β-D-galactopyranosyl - (1→3) - N - acetyl - D - glucosamine (lacto-N-biose I) isolated from the 'Bifidus factor' of human milk[3]. Disaccharide (2) was identified with

O-β-D-galactopyranosyl-(1→4)-N-acetyl-D-glucosamine which had been obtained from meconium[3] and from hog gastric mucin[4]. Disaccharide (3) was composed of glucosamine and galactose and contained the latter sugar as a reducing end-unit. The chromatographic behaviour and general properties of (3) indicated that it was most probably identical with 'lacto-N-biose II' isolated from a tetrasaccharide unit in the oligosaccharide mixture of human milk and was therefore O-β-N-acetyl-D-glucosaminoyl-(1→3)-D-galactose[5]. Disaccharide (4) possessed a high dextrorotation, about $[\alpha]_D + 150°$, and contained galactosamine and galactose. After reduction with potassium borohydride and hydrolysis, compound (4) gave galactosamine and dulcitol. Disaccharide (5) contained fucose and glucosamine and was found to be readily split into its component sugars on heating in *N* acetic acid at 100°.

Under the mild conditions recommended by Wallenfels, alkaline triphenyltetrazolium chloride reagent[6] is rapidly reduced by disaccharides (3) and (4), a reactivity which indicates the absence of a substituent from the secondary hydroxyl group adjacent to the reducing group in each material[7].

On treatment with dilute alkali, disaccharides (1), (3) and (4) gave some free N-acetyl amino-sugar and the corresponding free chromogen[8], whereas (2) remained apparently unchanged; and disaccharide (5) and β-D-galactosyl-(1→6)-N-acetyl-D-glucosamine[9] formed chromogens without being decomposed into their component sugars.

When tested under similar conditions with benzidine–trichloroacetic acid reagent, the disaccharides developed different colours. Substances (1), (3) and (4) produced a very dark brown colour, disaccharide (2) gave a golden-yellow spot, while substance (5) and β-D-galactosyl-(1→6)-N-acetylglucosamine[10] yielded a brownish-red spot.

The chromatographic behaviour and certain general properties of disaccharide (4), therefore, point to it being O-α-N-acetyl-D-galactosaminoyl-(1→3)-galactose, and disaccharide (5) as most probably being L-fucosyl-(1→6)-N-acetyl-D-glucosamine.

Evidence that N-acetylgalactosamine plays a definite part in the chemical structure responsible for A specificity was obtained when it was shown[11] that the agglutination of group A cells by extracts of *Vicia cracca* seeds and lima beans was inhibited by that acetylated amino-sugar and even more strongly by α-methyl-N-acetylgalactosaminide (unpublished observation by Dr. W. M. Watkins). Kabat and Leskowitz[12], using a quantitative precipitation technique, likewise demonstrated that N-acetylgalactosamine partially inhibited the precipitation of A substance by human anti-A serum. It was also shown that an enzyme obtained from *Trichomonas foetus* which destroyed A substance was specifically inhibited by N-acetylgalactosamine and its methyl glycoside[13].

The examination of certain of the materials described above in agglutination inhibition tests using human anti-A serum or lima bean extract has shown that disaccharide (4) is considerably more active than is N-acetylgalactosamine or its methyl glycoside when tested under similar conditions. It seems probable, therefore, that O-α-N-acetyl-D-galactosaminoyl-(1→3)-galactose is a structure more closely associated with A specificity than any that has been identified so far.

We wish to thank Prof. R. Kuhn for specimens of lacto-N-biose I and galactosyl-(1→6)-N-acetylglucosamine, and Prof. P. György for a preparation of β-D-galactopyranosyl-(1→4)-N-acetylglucosamine.

Extraction of Thyrotrophic Hormone from Human Pituitaries

So far as we are aware, thyrotrophic hormone has not been extracted from human pituitaries although pituitary tissue has been assayed for thyrotrophic hormone activity[1]. The amount of adrenocorticotrophic hormone stored in human pituitaries has been reported previously[2] and in this communication we present our findings with thyrotrophic hormone.

A total of twelve adult human pituitaries, divided into three batches of 3, 4 and 5 glands (see Table 1 for salient autopsy features), were extracted and assayed for thyrotrophic hormone activity. The pituitaries, none of which was from a case of a primary endocrine disorder, were stored whole in deep freeze until sufficient material had been collected.

The glands were cut into small pieces and triturated in a mortar for 10 min. with 0·9 per cent sodium chloride solution pre-chilled to 0° C. and a little coarse acid-washed sand until a fine pasty suspension resulted (10 ml. saline solution to 1·0 gm. wet weight of gland tissue). The suspension was centrifuged at 3,000 r.p.m. for 15 min. at 0° C. A second 0·9 per cent saline extraction of the residue was made and the two extracts combined. The *p*H was adjusted to 4·0 by addition of *N* hydrochloric acid and the slight precipitate was collected by centrifuging. This precipitate showed no thyrotrophic hormone activity and was discarded. Acetone pre-chilled to − 15° C. was added slowly to the supernatant solution to a final concentration of 75 per cent (v/v). After the mixture had stood for 1 hr. in the cold, it was centrifuged and the precipitated material washed with acetone and ether and dried *in vacuo* over phosphorus pentoxide.

The extracts were tested by the thyroid histology method of Junkmann and Schoeller[3] as modified by Heyl and Laqueur[4]. One Heyl–Laqueur unit of thyrotrophic activity is defined as the daily amount required to produce a definite histological change in the thyroid in 67 per cent of immature guinea pigs

Table 1. SUMMARY OF CASES USED FOR THYROTROPHIC HORMONE EXTRACTION

Batch No.	No. of glands	Sex	Age (years)	Autopsy diagnosis	Time of autopsy after death (hr.)
1	4	F	18	Chronic glomerulo-nephritis : cystitis : uræmia	3
		F	60	Mitral stenosis ; auricular fibrillation : auricular thrombus formation : embolism	2½
		F	49	Mitral stenosis (operation – valvotomy) : embolism : pericarditis	6
		M	74	Silicosis : broncho-pneumonia : cor pulmonale : tuberculous pericarditis and lymphadenitis	3
2	3	F	76	Megaloblastic anæmia : primary benign hypertension : gall-stones : empyema of gall-bladder	1½
		F	61	Bilateral renal calculi : bilateral pyonephrosis : uræmia	4
		F	58	Prolapsed disk : diffuse hepatic fibrosis : chronic pyelonephritis	5
3	5	M	57	Carcinoma bronchus : metastases in liver, lymph nodes, brain : purpura (hæmorrhage from stomach)	5
		M	56	Lobar pneumonia	2
		M	38	Carcinoma colon : metastases in lymph nodes and liver : obstructive jaundice	5
		F	16	Mitral stenosis : mural thrombus (left ventricle) : embolism	3
		M	59	Ulceration of rectum (perforation) : acute generalized peritonitis	6

Table 2. THYROTROPHIC HORMONE CONTENT OF HUMAN PITUITARIES

Batch No.	No. of glands	Total weight (mgm.)	Weight of dry powder extracted (mgm.)	Heyl–Laqueur μ/mgm. (approx.)	Total TSH in batch (Heyl–Laqueur units approx.)	Average Heyl–Laqueur units per gland (approx.)
1	4	2,614	205	0·25–0·5	51·25–102·5	13–26
2	3	2,075	110	0·5	55	18
3	5	2,814	81	1·0	81	16

(120–150 gm.) after 72 hr. (1 Heyl–Laqueur unit is equivalent to 1 Junkmann–Schoeller unit and is approximately equal to 0·1 I.U. thyrotrophic hormone). The intraperitoneal injection is divided into two equal daily doses on the first two days.

The results are presented in Table 2.

It would appear that the 'average' adult pituitary stores approximately 18 Heyl–Laqueur units of thyrotrophic hormone (about 2 I.U.) or about half the amount excreted in the urine *per diem* by some hypothyroid patients[5]. It is believed that in man this hormone and adrenocorticotrophic hormone are produced by the basophil cells of the anterior hypophysis, but the evidence for this is of an indirect nature and conclusive proof is still awaited. If thyrotrophic hormone and adrenocorticotrophic hormone are produced by the same cells, it seems likely that the degranulation of the basophils occurring as a result of stress[6,7] must have some influence on the yield of stored hormones from the gland. This is being investigated at present and the findings should add something to our knowledge of the reaction of the pituitary gland to stress.

Alteration of the Duration of Action of Parathyroid Hormone after Partial Purification

THE earliest methods of assaying parathyroid hormone depended on its ability to cause a rise in the concentration of plasma calcium in normal dogs 16–18 hr. after injection[1]. Recently, Davies *et al.*[2] have described a method of assaying this calcium-mobilizing factor, utilizing the parathyroidectomized rat as the test animal. Following the subcutaneous injection of crude parathyroid extracts (or 'Parathormone', Eli Lilly) into such animals the concentration of plasma calcium begins to increase in 2–3 hr., reaches a peak in 14–18 hr. and remains elevated for a total of 32–40 hr. (Fig. 1). On the basis of these facts, Davies *et al.* suggested that an adequate assay could be achieved by measuring the calcium concentration immediately before, and 18 hr. after, the injection of the test material ; and comparing the change with that occurring in a similar group of animals given a standard preparation.

Using the assay method essentially as they describe, we have been able to confirm their work,

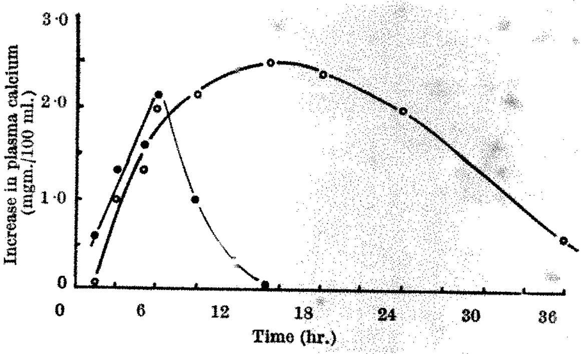

Fig. 1. The changes in plasma concentration of parathyroidectomized rats following the subcutaneous injection of 50 units 'Parathormone', Eli Lilly (○—○), and 0·5 mgm. of a partially purified gland extract (●—●). Each point represents the mean of eight to twelve determinations

and have found it quite adequate for assaying crude extracts prepared in a variety of ways. However, attempts to fractionate these crude extracts by several means resulted in a considerable or total loss of calcium-mobilizing activity when assessed in this manner. These apparently inactive preparations were shown to have considerable calcium-mobilizing activity when the plasma was analysed at 6 hr. rather than 18 hr. after the test injection. An investigation of the time-course of action of such preparations demonstrated that, after their subcutaneous injection, the concentration of plasma calcium begins to rise within 1–1½ hr., reaches a peak at 5–7 hr., and falls to control values in 12–14 hr. (Fig. 1). The duration of action can be prolonged if the material is suspended in arachis oil before injection.

This situation is reminiscent of that encountered in the purification of the corticotropins and is of at least three-fold importance: (1) Assay methods based on the increase in plasma calcium concentration 16–18 hr. after injection are probably unsuitable for assessing the purity of hormonal preparations. (2) The findings of all previous studies based on such an assay method should be critically re-examined since a reported loss of activity may well have been a conversion of a long-acting into a short-acting hormone. (3) Until more is known, comparisons between the calcium-mobilizing to phosphorus-excreting potency of a given preparation are of questionable value, particularly if measured over different intervals of time, as has been the custom in the past.

Our rapidly acting parathyroid extracts have been prepared by several different methods. The most reliable to date has been initial extraction of a fat-free gland powder with 0·2 *N* hydrochloric acid, followed by ultra-filtration through a 'Visking' membrane, and then separation on a 'Dowex' 50 × 4 ion-exchange resin. The activity of such preparations when measured by means of a 6-hr. assay (similar in other details to that of Davies *et al.*) is 75–100 units/mgm. dry powder. The methods of preparation and assay are at present being developed and modified, and a more complete description will be published shortly.

This investigation was supported in part by a grant (*A*.1331) from the U.S. Public Health Service.

Effect of Acetylcholine and Adenosine on Cardiac Cellular Potentials

WE have been impressed by the similarity of the effects of acetylcholine and adenosine on the membrane-resting and action potentials of guinea pig myocardial fibres. There are a number of reports of the effects of acetylcholine on the membrane-resting and action potentials of myocardial fibres[1-4]; but we have seen no report on the effects of adenosine or of their similarity to those of acetylcholine.

Our experimental method and apparatus were similar to those described previously[5]. Experimental error was reduced by recording from one single fibre throughout each experiment. The electrode remained in the one cell for periods up to 4½ hr. with no significant change in the membrane-resting and action potential. It was possible by this method to observe changes in the membrane-resting potential with an accuracy of ± 1·5 mV. (this limit was set by a combination of amplifier drift and spontaneous variations in the resting potential). The preparations were driven at a constant rate of 240 per min.

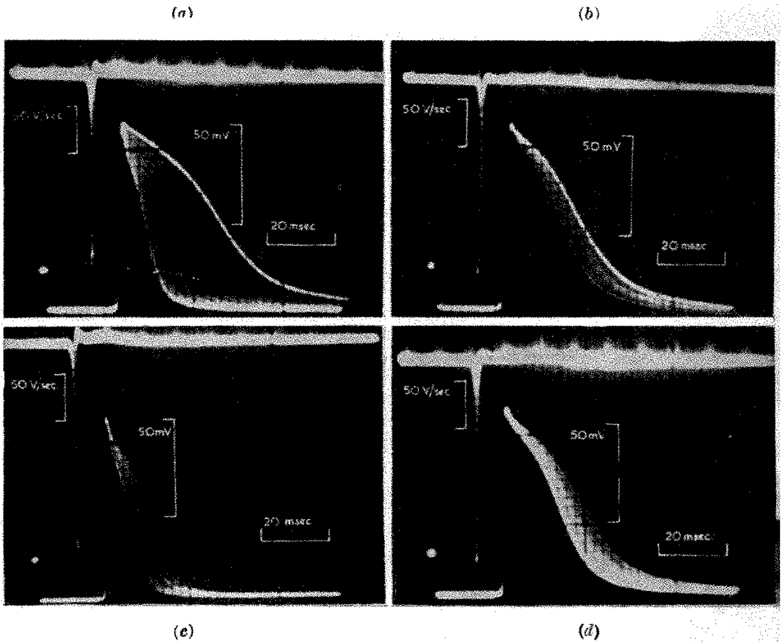

Fig. 1. The effects of acetylcholine and adenosine on the membrane action-potential of a guinea-pig atrial fibre. (*a*) Effect of 0·5 μgm./ml. of acetylcholine; (*b*) effect of 5 μgm./ml. of adenosine; (*c*) effect of 0·5 μgm./ml. of acetylcholine on the action potential already shortened by 50 μgm./ml. of adenosine; (*d*) effect of 50 μgm./ml. of adenosine alone. Upper trace in each illustration: first derivative of the action potential displaced to the left to prevent interference with the lower trace. Lower trace in each illustration: action potential. The above records were obtained from the same fibre and each record is a photograph of several successive action potentials and their first derivatives following the administration of the drug

In the atrium, adenosine (5–50 μgm./ml.) and acetylcholine (0·5–1 μgm./ml.) caused a pronounced increase in the rate of repolarization of the action potential without affecting its maximum rate of depolarization, conduction velocity, or the membrane-resting potential (see Figs. 1*a* and 1*b*). These effects rapidly disappeared after washing out the drugs.

The effects of acetylcholine but not those of adenosine were reversed or prevented by atropine sulphate (1 μgm./ml.). Furthermore, the effects of the two substances did not appear to be additive since the degree of acceleration of repolarization produced by a submaximal dose of acetylcholine was the same whether the acetylcholine acted alone or in conjunction with adenosine. Fig. 1*d* demonstrates the effect of 50 μgm./ml. of adenosine; acetylcholine (0·5 μgm./ml.) further increased the rate of repolarization (Fig. 1*c*) to the same degree as when given alone (Fig. 1*a*). These findings suggest that the two substances have different sites of action on the fundamental mechanisms responsible for the repolarization phase.

In the ventricle, concentrations of adenosine up to 50 μgm./ml. or of acetylcholine up to 2·5 μgm./ml. had no effect on the membrane-resting or action potential.

The effects of acetylcholine that we have found differ from those described by other workers[1,4], who find an increase in the resting potential of atrial fibres, with an increase in the maximum rate of depolarization and a reduction in the conduction velocity[4]. Apart from these exceptions, for which we have no explanation, the effects of acetylcholine which we report are essentially similar to those found by Hoffman and Suckling[2] and Woodbury and Brady[3].

It is of interest to note that Rand and Stafford[6], using the intact guinea pig heart *in situ*, have found a similarity in the effects of acetylcholine and adenosine; both substances block atrioventricular conduction and are potentiated by cardiac glycosides.

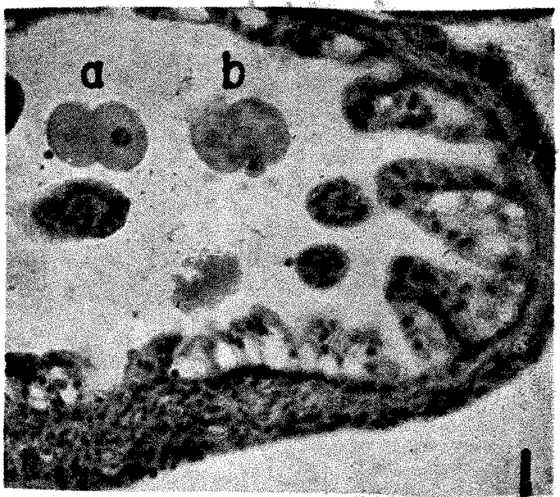
DL-Methionine (Sulphur-35) for labelling Unfertilized Mouse Eggs in Transplantation

IN transplanting mammalian eggs to a fertile female, one can distinguish the fœtuses developed from transplanted eggs among recipient 'native' fœtuses by a genetic marker. The transplanted fœtuses from a brown mouse, *C57BR*, have pigmented eyes, and the fœtuses developed from the native eggs of a Bagg albino (*B4LB/c*) recipient are not pigmented. Such a technique has been used for testing the survival of eggs after various treatments[1]. However, colour of eyes of mouse fœtuses cannot be observed until near the end of gestation. Labelling transplanted eggs with a radioactive isotope would serve as a means of distinguishing these eggs from native ones. The investigator could then determine the effect of any treatment of these eggs *in vitro* upon their fertilizability and early embryonic development after transplantation. Recent results obtained support the application of such a method.

Unfertilized mouse eggs were labelled with DL-methionine (sulphur-35) while they were in the growing follicles. In all instances 30–45-day-old *C57BR* females were donors of eggs. Ovulation was induced by injecting intraperitoneally 2 I.U. of equine gonadotropin 60 hr., and 4 I.U. of human chorionic gonadotropin 13–14 hr. before the eggs were collected. Developing eggs were labelled *in vivo* by an intraperitoneal injection of 25 μc. of DL-methionine (sulphur-35) 4–8 hr. after the female received equine gonadotropin.



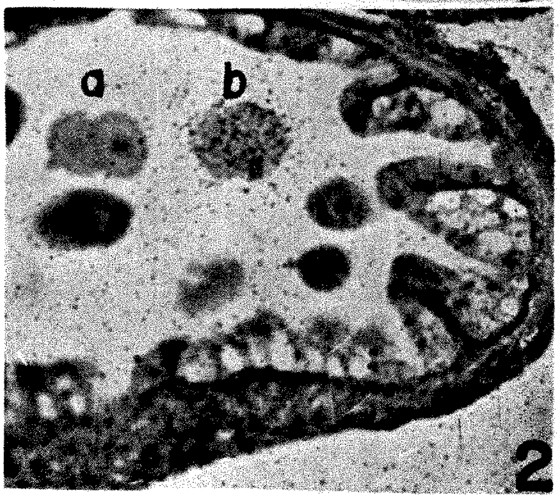


Fig. 1. Section of oviduct of recipient mouse containing two eggs (*a* and *b*) at two-celled stage. (× 185)

Fig. 2. The corresponding autoradiograph. Note radioactivity is present only in transferred egg, *b*. (× 185)

Subsequent to ovulation, tagged, unfertilized eggs were treated as follows: (1) Ampullæ with eggs were excised, fixed and sectioned for autoradiographical examination[2,3]. Radioactivity was found in the cytoplasm of all eggs thus examined and in the granulosa tissue surrounding them. (2) Some eggs were removed from the ampullæ, mounted on a copper planchet, and mixed with a gelatin solution[4] for activity assay in a flowing gas counter. The radioactivity of a dry mount of 35 labelled eggs was 29·1 counts per min. (3) Another group of eggs was recovered from the ampullæ and transferred into the bursa ovarii[5] of fertile Bagg albino females which had been mated 1 hr. earlier. These eggs, fertilized in the recipients, were allowed to develop during the gestation period in order to ascertain whether or not the radioactivity in the tagging technique was detrimental. Such eggs were observed to result in normal progeny. (4) Some eggs were transferred into fertile mated recipients, and their oviducts prepared for autoradiographical examination. Results indicated that, during superovulation, mice can receive 25 μc. DL-methionine (sulphur-35) intraperitoneally with little, if any, effect upon survival of their eggs. Occasionally a radioactive egg was found in a state of degeneration. However, as evidenced by eye colour, nine normal fœtuses resulted from the transplantation of twenty-nine labelled eggs into four recipients. In one case four brown young, which had developed from labelled eggs, were born.

The method described above permits the labelling of unfertilized mouse eggs with DL-methionine (sulphur-35) for their subsequent identification during early embryonic development. Successful application of this method is illustrated in Figs. 1 and 2. Fig. 1 shows a section of the oviduct of a recipient with two eggs at the two-celled stage. One egg, *a*, was natively ovulated and unlabelled, and the other egg, *b*, was radioactive and was transferred from an isotope-treated donor while it was unfertilized. These two eggs can be identified in the corresponding autoradiograph (Fig. 2), in which radioactivity is indicated only in egg *b*.

Precursors of Embryonic Chick Proteins

WE wish to report some preliminary findings obtained in the course of a rather extensive investigation into the nature of precursors of embryonic chick proteins (for some recent reviews, see refs. 1 and 2). In these experiments, amino-acids, chicken serum globulin and ovalbumin, labelled in their sulphur amino-acids with sulphur-35, were prepared. *Torulopsis utilis* was grown on sulphur-35 sulphate (obtained from Oak Ridge National Laboratory), according to Wood and Perkinson[3]; after extracting the yeast protein with organic solvents[4] it was hydrolysed with a 1 : 1 mixture of 6 *N* hydrochloric acid and 90 per cent formic acid. The humin was removed by centrifugation, and a portion of the neutralized hydrolysate corresponding to 50 mc. of the original sulphur-35 sulphate was injected intraperitoneally into a laying White Leghorn hen in two doses, about five hours apart. Eight hours after the second injection the blood was withdrawn by heart puncture, allowed to clot and serum globulin prepared[5]. The oviduct was removed from the hen and ovalbumin prepared essentially as described by Steinberg and Anfinsen[6]. Both proteins were treated with cysteine at a *p*H of 8·0–8·5 to assure removal of all exchangeable sulphur-35, and were afterwards dialysed. Peptides were prepared by peptic hydrolysis[7] of the ovalbumin and of the serum globulin. Aliquots of the radioactive amino-acids, ovalbumin, ovalbumin peptides, serum globulin or serum globulin peptides were counted as described for proteins, peptides and amino-acids[7]. Others were injected into the yolks of unincubated, embryonated White Rock eggs. The eggs were first swabbed with 70 per cent ethanol at the place to be injected; a small hole was made in the side of the egg, and 0·05–0·1 ml. of the radioactive solution containing 0·3–1·8 mgm. and 6,000–25,000 counts per min. was injected into the yolk. The hole was immediately sealed with paraffin, and the eggs were incubated at 38° C. under conditions of controlled humidity. Two to three dozen eggs were normally injected with one of the protein precursors. Starting with the fifth and ending on the ninth day after the injection, embryos were harvested and a number pooled. The mixture was homogenized for about 3 min. in a Potter–Elvehjem homogenizer in Ringer's or isotonic saline solution, made up to either 10 ml. (fifth and sixth days) or 20 ml. (seventh–ninth days) and precipitated by the addition of 40 per cent trichloroacetic acid, to a final concentration of 8 per cent. Dry protein powders were then prepared and counted to within 5 per cent of standard deviation, corrections for self-absorption and decay being made in each case[7].

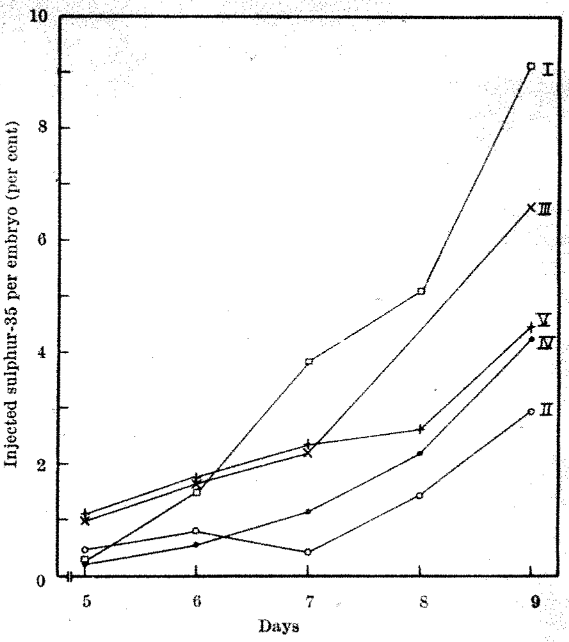

Fig. 1. I, Amino-acids; II, ovalbumin; III, ovalbumin peptides; IV, globulin peptides; V, serum globulin

The results of these experiments are presented in Fig. 1. It is apparent from the curves that over the period investigated there is, within our experimental error, no gross difference (an order of magnitude, or more) in the percentage of the injected protein precursor found per embryo. When one considers, however, that the protein injected is diluted with at least a portion of the yolk protein, approximately 3 gm. total[8], while the amino-acids and peptides are essentially not diluted at all since there are only negligible, if any, amino-acid or peptide pools in the yolk[8], one must conclude that proteins are the preferred precursors of embryonic protein. Furthermore, it is interesting to note that the egg protein ovalbumin is not used to any greater extent than the somewhat more 'foreign' protein serum globulin. This would indicate that these proteins are assimilated by the embryo by pathways having at least some intermediates in common. A similar interpretation might be made with respect to our peptide data.

Free amino-acids, if these were the true intermediates, would be expected to give much higher incorporation values in our experiments with injected sulphur-35 amino-acids than those actually observed. It is therefore tempting to conclude that the intermediates are either 'activated' amino-acids (or small peptides) (which are, on thermodynamic grounds, preferentially derived from protein) or that the processes of breakdown of injected protein and protein synthesis take place at two sites in such close proximity as to preclude any appreciable equilibration with injected amino-acids. The latter interpretation would be in accord with those recently suggested by Lotfield and Harris[9] and by Walter *et al.*[7] for other systems. However, it is not unreasonable to assume that proteolytic activity is largely centred in the yolk[10] and is therefore physically separate from the anabolism taking place in the embryo proper. Thus, our view at present is that the intermediates are activated forms of amino-acids directly derivable from proteins[11] and that added amino-acids and peptides join the common pathways at this junction.

Histochemical Appearances of Cholinesterase in the Submaxillary and Sublingual Salivary Glands of the Rat

DESPITE the researches of Babkin[1] and others, no definite conclusions have been reached with regard to the relative part played by the sympathetic and parasympathetic nerve fibres in the regulation of salivary secretion or the exact mode of termination of the fibres in the vicinity of the secretory units of the glands. It was considered that a histochemical study of the distribution of cholinesterase in the submaxillary and sublingual salivary glands of the rat might shed light on the problem.

Twenty-two mature rats were used for the present investigation. Parts of the submaxillary and sublingual glands were processed at the same time under identical conditions. The glands were fixed in 10 per cent formol saline for 6 hr. Frozen sections 10–25μ thick were then cut and washed in distilled water for 12 hr. These sections were then processed using the histochemical technique described by Koelle[2] and modified by Couteaux and Cöers[3]. The sections were incubated with the substrate for 12, 24, 36, 48 and 96 hr. at *p*H 4·2. The cholinesterase appearances in the salivary glands were assessed by studying the concentration and distribution of the copper sulphide precipitate formed. Hæmatoxylin and eosin or toluidine blue were used as counterstains.

In order to distinguish between the cholinesterase group of enzymes and the other esterases a number of the gland sections were treated with incubating solutions also containing 3×10^{-5} *M* concentrations of eserine. An attempt was made to distinguish between true and pseudo cholinesterase by using acetyl thiocholine iodide and butyl thiocholine chloride as substrates. In addition 10^{-6} *M* concentrations of di-isopropylfluorophosphate and 3×10^{-5} *M* concentration of 1-5-*bis* (4 allyldimethylammonium phenyl) pentan-3-one dibromide were used as inhibitors.

In the submaxillary gland, after 12 hr. incubation with acetyl thiocholine iodide, cholinesterase was found to be present in the nerve trunks accompanying the interlobular ducts. In those sections which were incubated for 24 hr. cholinesterase was present in the form of a fine network around the outside of the acini, which in places united with the nerve trunks. No cholinesterase was seen in the acinar cells; but a small amount was present in the nuclei and cytoplasm of many of the duct cells. No cholinesterase was found in the sections of the submaxillary glands incubated with butyl thiocholine chloride.

The inhibitors gave the following results. Eserine completely inhibited all enzyme activity in the submaxillary salivary gland. The sections treated with 1-5-*bis* (4 allyldimethylammonium phenyl) pentan-3-one dibromide showed complete absence of the cholinesterase network around the acini and the concentration of the enzyme in the nerve trunks was considerably reduced. Cholinesterase was no longer visible in the duct cells. The sections treated with di-isopropylfluorophosphate showed complete absence of cholinesterase, indicating that the concentration used completely inhibited both the true and pseudo cholinesterase activity.

In the sublingual gland, after 12 hr. incubation with acetyl thiocholine iodide, cholinesterase was present in the nerve trunks but was less concentrated than that seen in the nerves of the submaxillary gland. In the sections which were incubated for 48 and 96 hr. cholinesterase was seen to be present as a faint network around the acini, which had a similar appearance to that seen in the submaxillary gland; but the concentration of the enzyme was again very much less. No cholinesterase was found in the acinar cells; but a small amount was present in the nuclei and cytoplasm of many of the duct cells. No cholinesterase was found in the sections of the sublingual gland incubated with butyl thiocholine chloride. The effect produced by the different inhibitors was identical to that seen with the submaxillary gland.

These preliminary observations show that in the submaxillary and sublingual glands a small amount of true cholinesterase is present in the nuclei and cytoplasm of the duct cells but is absent from the acinar cells. In addition, they show that true cholinesterase is present in the form of a fine network around the acini of both glands but is much less evident around the acini of the sublingual gland. The fact that the net unites with the nerve trunks would suggest that it is formed of nerve fibres which contain true cholinesterase. Koelle[4] found in the cat, rabbit and rhesus monkey that the concentration of true cholinesterase was higher in cholinergic neurones than in adrenergic and sensory neurones. The present results indicate that the acini of the submaxillary gland of the rat are supplied with a high proportion of cholinergic nerve fibres whereas those of the sublingual gland are supplied with nerve fibres containing a low concentration of cholinesterase and are thus possibly adrenergic.

Vascular Compartments in the Rat Spleen

INJECTION of radiopaque media either directly into the spleen of the rat or retrogradely into tributaries of the portal venous system, followed by radiography, demonstrates the presence of distinct vascular compartments in the spleen and clarifies certain features of their venous drainage.

Previous evidence for this subdivision in the spleens of other mammals has been based on the following grounds.

(1) *Morphological*—(*a*) the arrangement of the splenic vessels into five or more pedicles which enter the spleen at fairly regular intervals; (*b*) the notched border of the spleen; (*c*) the occasional presence of accessory spleniculi.

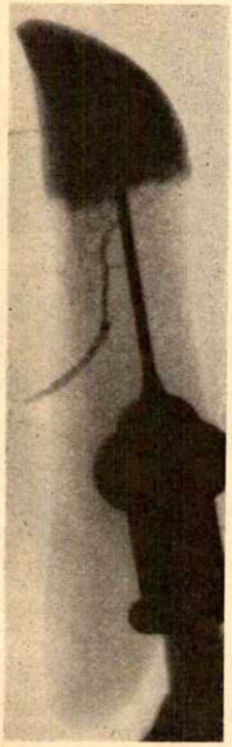

Fig. 1. Radiograph taken immediately after injecting 0·36 ml. 'Thorotrast' into the upper compartment of the rat spleen. (× 2)

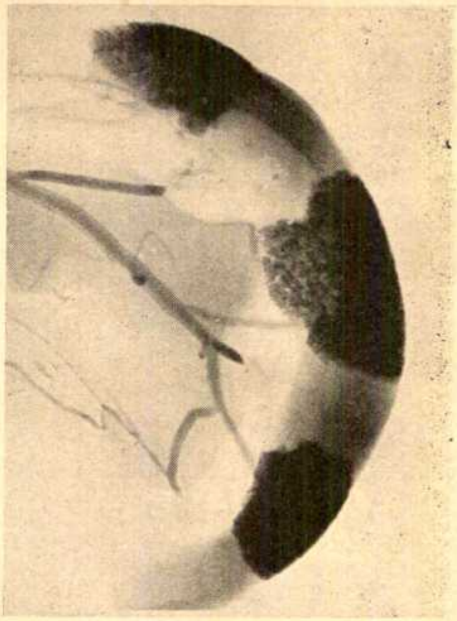

Fig. 2. Radiograph taken 30 sec. after injecting 3 ml. 'Micropaque' into the superior mesenteric vein. Alternate splenic vessels were interrupted before injection. (× 2)

(2) *Embryological*—the fact that the spleen develops from several primordia in the dorsal mesogastrium.

(3) *Stimulation Experiments* (in the dog). Electrode stimulation of one vascular pedicle results in a localized contraction of a single zone.

(4) *Pathological*—the localized areas of infarction following vessel occlusion.

Recently, Dreyer and Budtz-Olsen[1] have suggested that there may be compartments in the human spleen. Their evidence is that a radiopaque medium injected into one zone of the spleen is drained by the nearest vein without diffusion through the splenic parenchyma.

We have studied the passage of media in more than a hundred living rats, taking radiographs during injection and at varying intervals after. To obviate injection artefacts we have also undertaken similar procedures on the spleen of dead animals.

The splenic compartments in the rat vary in number between five and seven, of which the largest is the middle. Each is supplied by a branch of the splenic artery and drained by a tributary of the splenic vein.

Direct injection into the spleen of small amounts (0·06–0·18 ml.) of a radiopaque medium such as 'Thorotrast' or 'Micropaque' (Damancy and Co., Ltd.) is followed immediately by drainage through the vein of that compartment and is complete after 10–15 min. If the compartment becomes overloaded by an excess of injection mass additional drainage is afforded by the intersegmental vein (Fig. 1), which links together the veins of the individual compartments. There is no diffusion between pulp spaces of adjacent compartments for no direct communication exists between them. Obstruction of the compartmental vein is followed by opening up of the intersegmental vein, which constitutes the collateral channel. Interruption of alternate veins followed by retrograde injection into a tributary of the portal vein demonstrates the splenic compartments most effectively (Fig. 2) and indicates their relative sizes.

It is therefore presumed that since each compartment has an independent arterial supply and venous drainage it may be capable of independent activity and only when the blood supply to the spleen is excessive does the organ function as a complete entity. A pre-requisite for such activity is the opening up of the intersegmental vein, which integrates the venous drainage for all compartments.

Preliminary studies on the arterial arrangements strengthen this concept. The results will be published in full elsewhere.

Biochemical Tests for Malignancy applied to a New Strain of Human Cells

TRANSFORMATIONS of normal cells of rats and mice into malignant strains have been reported to occur under tissue culture conditions on a few occasions[1], and in such cases it was possible to demonstrate their malignancy by inoculation into the appropriate animal strains. During tissue-culture experiments with human cells, an abnormal strain appeared in roller-tubes of liver cells from a 20-week embryo. The new strain showed some of the characteristics of malignant cells, and we had to rely on biochemical tests to obtain further evidence of their malignancy.

We used for the comparative tests human embryonic cells from skin, kidney and lung tissues and three carcinoma strains which originated from human tumours: these latter are the *HeLa* strain and strain *HEP* 1, both of which came from cervical epidermoid carcinoma, and strain *HEP* 2, which came from an epidermoid tumour of the larynx of a man. The new strain (designated *HLM*) is distinguished by morphology, cell mass and protein content from the carcinoma strains. All the cells were grown from cell suspensions in a medium consisting of modified Connaught medium 858[2], 5 per cent chick embryo extract and 20 per cent human serum.

Deoxyribonucleic acid phosphorus was determined, and hæmocytometer counts were made on suspensions of nuclei from the skin fibroblasts, the carcinoma strains and strain *HLM*. The deoxyribonucleic acid phosphorus content per nucleus (Table 1) was of the normal diploid value[3] for the skin cells, but gave tetraploid values for the carcinoma cells and strain *HLM*. Chromosome counts and deoxyribonucleic acid determinations made by other investigators indicate that a tetraploid nucleus may be a consistent feature of human and animal carcinoma cells (cf. ref. 4).

Table 2. COMPARISON OF METABOLIC QUOTIENTS IN TERMS OF CELL NUMBER FOR HUMAN LEUCOCYTES, AND EMBRYONIC AND CARCINOMA CELLS

Cells	Reference	µmoles per 10^9 cells per hr.	
		Q (Glucose consumed)	*Q* (Lactic acid produced)
Normal leucocytes	Beck and Valentine (ref. 8)	140	301
Chronic myelocytic leukæmia		52	127
Chronic lymphocytic leukæmia		31	48
Human embryonic cells	Leslie, Fulton and Sinclair	121	187
Human carcinoma cells		77	70

The metabolic quotients (Tables 1 and 2) have been obtained by relating glucose consumption and lactic- and keto-acid production over 72-hr. growth periods to the corresponding average amount of nucleic acid phosphorus or to the average cell number. The latter values were based on measurements of ribonucleic acid phosphorus and deoxyribonucleic acid phosphorus in sets of replicate tubes sampled at the start and finish of the tests.

Although the embryonic cells are widely different in origin and morphology, their quotients for glucose consumption and total acid production (that is, lactic- and keto-acids combined) are closely similar to one another and considerably higher than the group of values for the carcinoma cells and strain *HLM* (Table 1). That high glycolytic activity is common to both these rapidly multiplying embryonic and malignant cells grown under aerobic conditions is in keeping with the views of Weinhouse[5] and runs contrary to those of Warburg[6]. When insulin was present in the medium at a concentration of 0·1 unit per ml., ribonucleic acid phosphorus formation was stimulated in all cell types, but with embryonic cells the metabolic quotients were decreased relative to the control values, while with the carcinoma cells and strain *HLM* they were larger than the control values. In this connexion, Woods *et al.*[7] have shown that insulin stimulated anaerobic glycolysis in mouse melanoma slices but produced no response in brain slices.

The results in Table 1 clearly show that strain *HLM* belongs to the malignant group. The differences in glycolytic activity are features which distinguish other normal and malignant human cells. This is seen in Table 2, where we have compiled, on the same 'per cell' basis, the values obtained by Beck and Valentine[8] for the glycolytic activity of suspensions of normal and leukæmic human leucocytes in mano-

Table 1. DISTINGUISHING FEATURES FOR HUMAN EMBRYONIC AND MALIGNANT CELLS

Distinguishing features	Experiments	Units	Mean values and standard errors for the different cell types		
			Human embryonic cells	Human carcinoma strains	New strain *HLM*
Deoxyribonucleic acid phosphorus per nucleus	Normal medium	µgm. deoxyribonucleic acid phosphorus per million nuclei	0 69 ± 0·03	1·39 ± 0 04	1·43 ± 0 04
Q (Glucose consumed)	All tests Control Insulin	µmoles per mgm nucleic acid phosphorus per hr.	67·2 ± 2·60 61·8 ± 1·98 57·8 ± 1 00	18 4 ± 0 50 19 1 ± 0·19 26 3 ± 0 42	20·2 20·2 24·9
Q (Total acid produced)	All tests Control Insulin	µmoles per mgm. nucleic acid phosphorus per hr.	108·2 ± 3 9 100·0 ± 5·4 86·0 ± 3·6	16·6 ± 1 31 19·0 ± 1·21 27·2 ± 1·72	22·5 22·5 32·9

metric vessels and those we have obtained with embryonic and carcinoma cells by tissue culture procedures. The rates of glucose consumption and lactic acid production are of the same order for embryonic cells and normal leucocytes and are greater in each case than the values for the corresponding malignant cells.

A detailed account of this work is being prepared for publication. We wish to thank Dr. F. W. Sheffield, Department of Bacteriology, University College, London, and Dr. Alice E. Moore, Sloan-Kettering Institute for Cancer Research, New York, for kindly sending us the *HeLa*, and the *HEP* 1 and 2 strains respectively. One of us (W. C. F.) wishes to acknowledge the award of a grant by the Medical Research Council.

Note added in proof. The transformation of tissue culture lines of human epithelial cells to neoplastic forms has recently been established by cytological and inoculation techniques[9].

An Apparatus for eluting and concentrating Chromatogram Spots

A MAJOR problem in toxicological analysis is the separation of the poison from metabolites and body constituents that are co-extracted. This problem is especially acute in cases of poisoning by alkaloids. One technique that is of great use in solving this problem is paper chromatography[1-3]. The next step in the analysis is the identification of the alkaloid by such techniques as ultra-violet spectrophotometry, micro-colour tests and observations of the form of crystals obtained with various reagents. Recently, Clarke and Williams[4] have described a technique whereby 0·05 ml. of a solution containing 50 μgm. of alkaloid provides sufficient material for five hundred separate micro-colour and crystal tests. This quantity of alkaloid (50 μgm.) is about the amount most suited for initial purification by paper chromatography. We have, however, found difficulty in eluting the alkaloid from the chromatogram and concentrating the eluate into 0·05 ml. of solution without loss of alkaloid. A simple and highly efficient apparatus for accomplishing this operation is shown in Fig. 1.

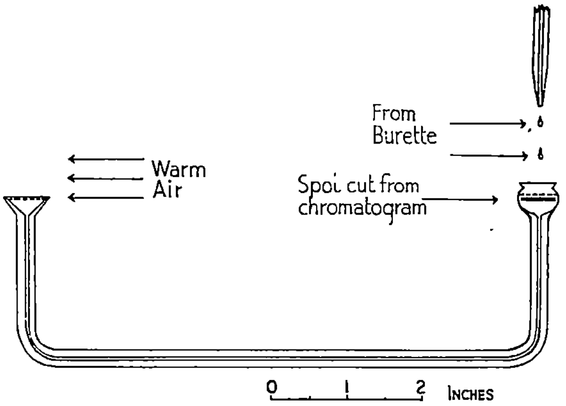

Fig. 1

The apparatus consists of a length of 1-mm. bore capillary tubing the ends of which are blown into small bulbs. The tubing is then bent as shown in the diagram. The spot cut from the paper is put in the larger right-hand cup and alcohol is dropped on to it from a burette, or siphoned on from a constant-head reservoir levelled with the solvent in the apparatus. An electric hair-drier blows a stream of warm air over the left-hand cup and as evaporation proceeds the paper spot is constantly washed by the addition of fresh alcohol. Concentration of eluted alkaloid occurs in the left-hand cup.

Experiments with spirit-soluble dye have shown that back-diffusion is negligible. While 50 μgm. of strychnine from a chromatogram run in butanol–acetic acid was quantitatively recovered and concentrated into 0·1 ml. using this apparatus, only 49 per cent of 50 μgm. of strychnine on a similar spot was recovered by soaking the paper in 5 ml. of alcohol for 5 hr. Quantitative measurements were by ultra-violet spectrophotometry.

Many alkaloids have an extremely low absorption in the ultra-violet. Atropine, for example, has peaks with E (1 per cent, 1 cm.) approximately 5. Nevertheless, if 100 μgm. of atropine can be concentrated into 0·5 ml. then optical density values of 0·1 will be obtained. This apparatus, coupled with paper chromatography and the use of micro cells for ultra-violet spectrophotometry, enables accurate measurements to be made for such alkaloids.

We have found it advantageous to concentrate the eluate in two stages ; first, into a volume of approximately 0·15 ml. and, secondly, using a micro-scale version of the apparatus, into approximately 0·05 ml.

The technique can obviously not be used for alkaloids run on a buffered paper chromatogram[3], but where butanol–acetic acid solvents have been used alcohol is an ideal eluent. The rate of evaporation is such that complete solvent exchange (approximately 1·0 ml.) in the apparatus is achieved in approximately 20 min. The rate of extraction depends on the compound. To achieve complete extraction we find it best to evaporate for approximately three hours, then to allow the paper to soak overnight and to evaporate for a further three hours the following morning.

This technique is obviously applicable to other problems requiring micro-continuous extraction and concentration. We hope to show further uses of it in forensic chemistry.

Pharmacological Inhibition of Acetylcholine Synthesis

SCHUELER[1] has designated as the "hemicholiniums" a series of quaternary bases[2] which exhibit an unusual kind of toxicity. Chemically they are characterized by the incorporation of a choline (or choline-like) moiety into a six-membered ring through hemiacetal formation. Their most striking pharmacological action is respiratory paralysis: this is central in origin and late in onset, and when the dose is not too large can be prevented by the administration of either eserine or choline. Schueler noted that hemicholinium intoxication presents several features reminiscent of poisoning by botulinus or tetanus toxin, and suggested that it might be due to interference with some cholinergic mechanism. We thought that a substance having such effects might be a specific poison of acetylcholine synthesis, and through Dr. Schueler's kindness we have been able to verify this notion with compound No. 3 of his series, here called *HC*3.

*HC*3 (2×10^{-5} *M*), added to the eserinized plasma perfusing a cat's superior cervical ganglion, did not affect the rate at which acetylcholine was released into the perfusion fluid during repetitive stimulation of the preganglionic nerve trunk for 1–2 min. With more prolonged stimulation, however, the rate of acetylcholine release rapidly declined, and coincidentally the ganglion lost its ability to transmit impulses and also most of its store of preformed acetylcholine. The acetylcholine synthesized by a ganglion during an hour's stimulation at 20/sec. was reckoned by comparing its residual acetylcholine content with that of its unperfused fellow and correcting for the acetylcholine discharged into the perfusion fluid. In five experiments with *HC*3 the amount synthesized was $0{\cdot}10 \pm 0{\cdot}09$ μgm. (mean ± S.D.), and in five experiments without the drug it was $1{\cdot}21 \pm 0{\cdot}17$ μgm. The effects of *HC*3 could be antagonized by raising the choline content of the perfused plasma. When the ganglion was stimulated during perfusion with eserinized Locke's solution instead of with plasma, it synthesized acetylcholine much more slowly, and synthesis was still further reduced if *HC*3 was present, or alternatively, if the concentration of eserine was increased. Evidence that eserine may interfere with acetylcholine synthesis has already been presented by Perry[3] and by Shelley[4].

Analogous results were obtained with *HC*3 in experiments on mouse brain, minced and incubated in eserinized bicarbonate–Locke as described by Mann *et al.*[5]. Under our experimental conditions this preparation synthesized acetylcholine at the rate of about 11 μgm./gm. (wet weight) in 4 hr.; *HC*3 (10^{-4} *M*) diminished the synthesis by at least 75 per cent; choline increased the synthesis and partly (2×10^{-5} *M*) or wholly (10^{-3} *M*) reversed the inhibitory effect of *HC*3. The release of acetylcholine from tissue to medium, which proceeded slowly throughout the period of incubation, appeared to be unaffected by *HC*3 or by choline, except in so far as the level of bound acetylcholine was altered.

*HC*3 was tested for its ability to inhibit the synthesis of acetylcholine by an extract of acetone-dried rat brain powder in a medium containing choline (10^{-2}–10^{-5} *M*), acetyl–coenzyme *A* (2×10^{-4} *M*) and cysteine (2×10^{-4} *M*). In this system it also acted as an inhibitor and its effect was again antagonized by choline; but its action was here so weak (for example, about 50 per cent inhibition by 10^{-3} *M* *HC*3 in the presence of 10^{-4} or 10^{-5} *M* choline) as to seem unrelated to its pharmacological activity. It is unlikely, furthermore, that *HC*3 acts by preventing the acetylation of coenzyme *A*: for (*a*) such an action might be expected to interfere with many essential metabolic processes, whereas the toxic effect of *HC*3 appears to be highly specific; and (*b*) we have found that the ability of homogenized pigeon liver to acetylate sulphanilamide, which depends on coenzyme *A*[6], is well maintained in the presence of 10^{-2} *M* *HC*3. It is conceivable that *HC*3 acts on intact nervous tissue by poisoning choline acetylase (that is, the enzyme that transfers acetyl groups from acetyl-coenzyme *A* to choline), but that the enzyme on being extracted from tissue becomes less susceptible to poisoning by *HC*3. An alternative explanation would be that *HC*3, and other hemicholiniums, may compete with choline for transport by a specific carrier system to intraneuronal sites of acetylation.

Chromatography and Spectrophotometry of Fused Salts

WE have recently observed chromatographic adsorption on alumina (Merck's reagent grade aluminium oxide) of transition metal cations dissolved in fused salts.

Solutions of Fe^{+++}, Co^{++}, Ni^{++}, Cu^{++}, UO_2^{++} in lithium-potassium nitrate eutectic mixture (lithium-potassium nitrate, 43 mol. per cent lithium nitrate, m.p. 132° C.) were placed in a jacketed 'Pyrex' tube (10 mm. internal diameter, 20 cm. long) filled to a height of 10 cm. with alumina. The temperature of the tube was maintained at 150° C. by circulating silicone oil ('Dow-Corning 710') through the jacket. The solutions were all approximately 0·01 *M* with respect to the transition metals and had been prepared by dissolving appropriate amounts of the anhydrous chlorides in lithium-potassium nitrate. All the transition metal cations listed are adsorbed on the column. They may be eluted with lithium-potassium nitrate containing the complex-forming anions Cl^-, $SO_2^{=}$, or CN^-. We are investigating the elution properties as a function of the particular complexing anion, its concentration and the temperature of operation of the column.

Essentially similar observations have been made using anhydrous ammonium formate (m.p. 118° C.) as a solvent.

In order to gain a better understanding of the nature and stability of the complexes formed, we are carrying out studies with a Beckman spectrophotometer which has been adapted for use at elevated temperatures in the following way: the usual Beckman compartment has been replaced by one through which cooling water may be circulated. The cell holder consists of a brass block with internal channels through which hot silicone oil is circulated from a constant-temperature bath. The usual 1-cm. 'Corex' absorption cells are used for containing the lithium-potassium nitrate solutions, care being taken not to allow the solutions to solidify in the cells to prevent cracking.

Marked changes have been observed in the spectra of the transition metal ions on addition of Cl^-, $SO_2^=$, or CN^-. The interpretation of these data in terms of stability constants for the various complexes formed will be published in detail elsewhere. These studies are being carried out over a range of temperatures to yield information on heats and entropies of formation of the complexes.

Barbulation induced in Silky Plumage by Thyroxine

A PECULIARITY of 'Silky' plumage in poultry is the absence of barbules in the main vane of the body feathers so that adjacent barbs lie free instead of interlocked, as is the case in the usual breeds. The trait behaves as a simple recessive, occurring only occasionally in other fowl[1]. However, a fairly comparable state of feathering is developed in the common fowl when these are thyroidectomized[2], or if they are treated with one of the goitrogens[3]. In such experimental fowl, the barbules are undeveloped and the individually separate barbs tend to become gradually more delicate and soft. These similarities suggest that the site of effect of the Silky gene is the feather itself, which will not respond at all to the thyroid hormone; or that in the presence of the Silky gene, the thyroid output is inadequate for full control of a possible normal differentiation.

Administrations of thyroxine (thyroxine crystals, Squibb, in distilled water) were made to Silky fowl of both sexes during enforced feather regeneration in test of these questions. Three male and three female Silkies were deplumed regionally and, upon evidence of new feather growth, injected subcutaneously with 0·5, 0·75 and 1·5 mgm. thyroxine, given as a single dose. The first two levels were ineffective; the third gave an evident, although peculiar, response. The barb segments showing an effect were swollen, sometimes forked and barbulated. Some attempts of sporadic barbules to differentiate hooklets were seen; these were atypical, ribbon-like formations. Several difficulties were encountered in the first series of experiments, the regeneration was extremely spotty and slow, and the new plumage was very delicate and readily injured. A later series of tests were made using the same birds and after allowing a rest period of six months. Here a single injection of 0·5 mgm. thyroxine was given to all birds at the time of defeathering; it was followed one week later with a second single dose of 2·0 mgm. With this treatment, regeneration was very prompt and fairly regular, and a good response to the 2·0-mgm. dose was everywhere encountered. The zone of feather barbs growing at the time of the second injection formed barbules that were distally modified in the usual manner. The body feather of the Silky fowl is accordingly capable of a differentiation beyond that characteristically achieved, and it will do so in presence of elevated thyroxine titres.

The male Silkies gave a somewhat better structural feather reaction than did the females; the general condition of all the birds was wholly unaffected to casual inspection and continued good. On a body-weight basis, the Silky fowl, the male especially, seems more tolerant of thyroxine than is the Brown Leghorn; this may be a general condition of which the resistance of the feather is a special instance. However, we know little of the normal thyroid performance in Silkies; it is hoped some observations in this respect may be available when the present material is submitted elsewhere in expanded, illustrated form.

I am indebted to Dr. Mary E. Rawles for a gift of the Silkies, and to Mr. Paul C. Harris for much kind assistance.

Astaxanthin in the Muscle of Cod

ASTAXANTHIN is probably the most common pigment of marine organisms. It has been found in a variety of species from unicellular algae to fish; it is particularly the typical pigment of the crustaceans.

In fish it is fairly widely distributed in the chromatophores in the skin, but normally occurs in the flesh only of the salmon and related species. It is therefore of considerable interest to report for the first time the occurrence of astaxanthin in the flesh of one specimen of cod (*Gadus callarias* L.). When the number of 'normal' cod caught and distributed for human consumption is considered, the occurrence of pink-fleshed cod must be a rarity.

This particular specimen was bought on the fish market in the town of Drammen, Norway, last September, to be used in a cooking course. It was noted for the bright red colour of the flesh, which resembled the colour of salmon flesh. The fish was taken to the State Research Institute of Home Economics, Stabekk, which submitted it to this laboratory for investigation of the pigment. It has been verified by several zoologists that the fish was a true cod. The pigment was extracted with acetone, and the absorption spectrum of the solution was measured directly in a recording spectrophotometer. The absorption curve is shown in Fig. 1. It agrees well with previous values reported for astaxanthin. The pigment was transferred to ether and washed with a solution of sodium bicarbonate. As no detect-

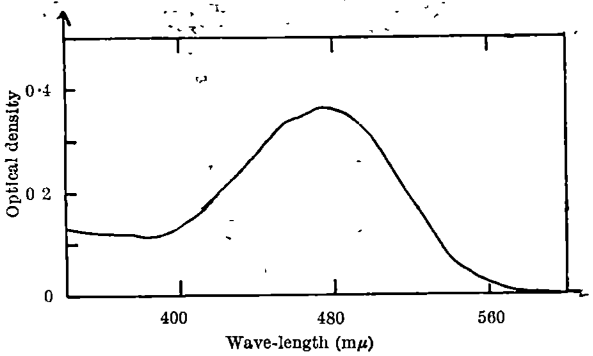

Fig. 1. Absorption spectrum of pigment from a specimen of *Gadus callarias* L. 21 gm. of muscle was extracted with 100 ml. acetone and the absorption measured in a 2-cm. cuvette

able amount of the pigment was removed with the water phase, it was concluded that the astaxanthin was mainly present in the esterified form.

A chemical analysis (performed at Stabekk) of the muscle has given the following results :

Dry matter	21·7	gm./100 gm. wet muscle
Protein	19·9	" " " "
Fat	0·4	" " " "

The data are representative of cod flesh which has lost a little water due to freezing and thawing.

There was nothing else exceptional about this cod than its peculiar pigmentation. The flesh had a good taste.

There is as yet no obvious explanation for this sporadic appearance of astaxanthin in cod flesh, but somewhat similar observations have been made on whales. Occasionally red (astaxanthin-containing) whale-body oils and whale-liver oils are encountered ; in this case pigmentation is taken to indicate an unspecified pathological condition[1,2].

Bacteriologically Sterile Planarians for Tissue Culture

ADULT individuals of *Planaria lugubris* O. Schm. of 0·7 cm. or more in length have been rendered bacteriologically sterile by treating for 2–3 days at room temperature in the dark with a mixture of 100 mgm. aureomycin hydrochloride, 100 mgm. chloramphenicol crist. and 25 mgm. trypaflavin (the latter against fungi, especially yeasts) suspended in 250 ml. tap-water. If not more than a few animals are treated in one flask (six animals to a 50-ml. Erlenmeyer flask with about 10 ml. fluid), and the trypaflavin concentration of 100 γ/ml. is not exceeded and the animals are shielded from light, the mortality caused by the sterilization procedure itself is negligible. Treated animals transferred to sterile tap-water and shielded from light have not been observed to die. A varying mortality occurred, however, during the test for sterility.

To test the animals for sterility they were transferred singly to flasks with sterile peptone–yeast water (5 gm. peptone B.D.H. and 250 gm. baker's yeast autoclaved in 1,000 ml. tap-water, cleared by centrifugation, adjusted to *p*H 7·2 with 0·1 *N* sodium hydroxide, diluted with tap-water 1 : 1 and autoclaved again for 20 min. at 121° C.). The transfer was performed in subdued artificial light. The flasks were stored away in the dark at room temperature. Animals surviving after five days in clear medium were used for tissue culture. So far not a single infection has occurred in tissue-culture experiments with animals thus tested.

Sterile nylon brushes were used for the transfer of the animals. These brushes were obtained by fastening bundles of short lengths of nylon bristle or fishing line between the jaws of inoculation needle holders.

A few series of tissue culture experiments have already been performed with the hanging-drop technique. Fragments of the lateral regions, 0·3–0·5 mm. in diameter, have been explanted on various mixtures of human blood plasma, human fœtal brain extract and 1 per cent solution of 'Titro-Salz' (Nordmark-Werke, Hamburg) at room temperature. Survival of at least six days has been obtained, but no active outgrowth. However, cell movements and cell migration have been observed. Histological examination of the cultures has shown loss of the original organization, presumably by haphazard movements of the different cell types. On the other hand, there was a certain tendency to form cyst-like structures, notably of epidermal tissue.

Previous attempts by Murray[1] to culture planarian tissue *in vitro* have been made with *Planaria dorotocephala* sterilized by ultra-violet irradiation. The osmotic value of the body fluids of *Planaria dorotocephala* must be considerably lower than that of the body fluids of *Planaria lugubris*, as indicated by the survival of small fragments of the latter species in media with the osmotic value of human blood plasma.

Sterilization of *Planaria gonocephala* Dugès and *Dendrocoelum lacteum* (O.F.M.) by the above mixture has resulted in the death of the animals, perhaps because of the lack of intense pigmentation, which may counteract the photodynamic action of the trypaflavin. Sterilization with the aid of hexachlorophene, 'Bradosol' (Ciba), 'Entero-Vioform' (Ciba), mercurochrome or methylparaben failed also with *Planaria lugubris*. All these substances proved to be lethal in bactericidal (fungicidal) and even bacteriostatic (fungistatic) concentrations.

The tissue culture trials took place in the Laboratory of Cytology and Experimental Histology of the University of Leyden. I am obliged to Prof. P. J. Gaillard, who prepared the first tissue cultures.

Splenic Hypertrophy in Voles

ENLARGEMENT of the spleen, induced by social stress, has been recorded in *Microtus agrestis*[1] and *M. orcadensis*[2]. Splenic hypertrophy also occurs in natural populations of *M. agrestis* at certain stages of their population-cycle (H. Chitty, personal communication).

The data reported here were obtained from a mixed group of *M. agrestis* which included both stressed and unstressed laboratory-bred animals, and also some from the field. In this group the range of body-weight was 11–40 gm., and of spleen weight 10–660 mgm. It was known from data previously accumulated in the Bureau that in normal unstressed animals, with a similar body-weight range, the spleen weight very rarely exceeded 80 mgm.

Spleens from more than thirty animals have been examined histologically. Enlarged ones are characterized by great congestion, the presence of extramedullary erythropoietic tissue, and large numbers of megakaryocytes. Some erythropoiesis occurs in the small spleens. With increasing spleen size the lymphoid tissue becomes less distinct, and in the largest spleens the Malpighian corpuscles are virtually obliterated. This decrease in the amount of lymphoid tissue in the spleen is consistent with the involution of the thymus reported in stressed animals[1,2].

It was clear from the beginning that the red cell picture was abnormal, and so this has been the main feature studied. The proportion of reticulocytes in the blood has been measured, and for the eighty animals examined, the range was 2–36 per cent. It appeared that a high reticulocyte count was associated with an enlarged spleen, indicating an increased rate of release of immature erythrocytes into the circulation. A preliminary statistical analysis, kindly carried out by Mr. P. H. Leslie, showed that, for a given body-weight, this association between a high reticulocyte count and an enlarged spleen was highly significant.

Hæmoglobin determinations on venous blood ranged from 64 to 115 per cent (100 per cent = 14·8 gm./100 c.c. with oxyhæmoglobin). Low hæmoglobin-levels were in the majority of cases associated with enlarged spleens and high reticulocyte counts.

More than thirty spleens were tested for hæmosiderin; significant amounts were present in only three of the enlarged spleens and in two of the small ones. There was no evidence that any of these animals were suffering from wounds or parasitic infestations sufficient to cause an abnormal blood picture.

There is thus clear evidence of a hæmolytic process in those animals with splenic hypertrophy. This condition is indicated by the large amounts of accessory erythropoietic tissue in the spleen; the high reticulocyte counts, and the low hæmoglobin-levels. However, the exact relationship between spleen size, reticulocyte count, and hæmoglobin content appears to be complex, and depends on the body-weight and sex of the animal, and probably on the particular stage of the condition reached. The ætiology of the hæmolytic process is as yet unknown.

This work would not have been possible without the advice and training facilities kindly provided by Dr. R. G. Macfarlane, Department of Hæmatology, Radcliffe Infirmary, Oxford; in particular I wish to thank Dr. A. A. Sharp for his suggestions and ready help. This is the first part of a fuller study being made in conjunction with Dr. D. Chitty.

Paromola cuvieri (Risso), a Crab new to the Orkneys, Shetlands and Norway

On June 25, Prof. O. Nybelin brought me for identification some photographs of a large 'spider' crab, four specimens of which had been received by the Natural History Museum, Gothenburg, Sweden, between July 1955 and February 1956. The local fishermen, who had trawled the specimens at four separate localities off the Shetlands and Norway, recognized that they were quite new to fishing grounds with which their families had been familiar for generations. I was not altogether surprised to find that they belonged to a species first recorded from the Mediterranean, namely, *Paromola cuvieri* (Risso), since I knew of another unpublished recent record from the Orkneys. Prof. Nybelin informed me that they had also taken several Mediterranean species of fish in the same waters in recent months. *Paromola*, with a span of 3–4 ft. and a shell 6–8·5 in. long, is not a true spider-crab but a relative of the sponge-crab *Dromia*. It may be recognized by its club-like eyes set on slender stalks and the short last pair of legs, each ending in a curious subchela. It exhibits marked sexual dimorphism of the chelipeds which in the female are very slender and not much longer than the shell; in the male about three times as long as the shell and stouter than the walking legs. The Portuguese call it *aranha do mar*, Algerian fishermen *diable* because of its reddish colour and bizarre appearance.

The distribution of *Paromola cuvieri* is generally given as: Mediterranean (excluding the Adriatic) and the adjacent North Atlantic waters from Cape Bojador and the Azores to Cork; and the maximum depth as 640 m. (about 350 fathoms)[1,2]. Apparently certain British records have been overlooked; Halbert[3] states that specimens were taken by the Irish Fisheries Investigations in September 1907 at a depth of from 627 to 728 fathoms (1,150–1,320 m.), in association with the deep-water coral *Lophohelia*, at 50° 42′ N., 11° 18′ W. He also mentions a shell and two chelipeds found long ago on the shore of Mull (B.M. Reg. No. 1877.1). Halbert was right in thinking that the crab was indigenous to deep water to the south-west of Ireland, and four males and two females were sent to the British Museum from this region between 1911 and 1948 (depth, 130–160 fathoms). He also predicted that *Paromola* would eventually be found in deep water off the west coast of Scotland, and two years later Ritchie[4] recorded a specimen trawled between the Flannan Islands and the Butt of Lewis (depth not given). On January 5, 1951, a female was taken off Stromness, Orkney (depth not stated; specimen in Royal Scottish Museum).

The recent northern records sent to me by Prof. Nybelin are as follows: (1) 150 nautical miles west to north of Sumburgh Head, Shetlands, about 150 fathoms, July 1, 1955. (2) North-west part of fishing ground 'Tampen' to north of Shetlands, 140 fathoms, about end of August 1955. (3) North-west of Utsire, on the west coast of Norway, 135 fathoms, February 1956. (4) On 'Egersundsbanken' off west coast of Norway, 82 fathoms, February 1956. The photographs are of male specimens, which are more often captured than females. That specimens sometimes wander into coastal waters is evident from various records; Orton[5] recorded a male from 15 fathoms off the Cornish coast, and in 1919 another male, now exhibited in the public gallery of the British Museum (Natural History), was taken four miles west of the Lizard in 27 fathoms. The large male found alive in only 2 ft. of water on the Cork coast probably strayed from much deeper water, because Halbert mentions that one of the epizoic organisms, the hydroid *Sertularella gayi* (Lamouroux), is found in fairly deep water. In recent years *Paromola* has extended its range, via the west coast of Scotland, to the waters around the Orkneys, Shetlands and the southern part of the Norwegian west coast.

Naphthaquinone Pigments in the Tropical Sea Urchin *Diadema antillarum* (Philippi)

In addition to black pigment[1], the sea urchin, *Diadema antillarum*, contains abundant red and purplish pigments.

Extracts of spines, test, peristome, periproct, podia, gut wall, radial water vascular canals and nerve cords, axial complex and amœbocytes of the cœlomic fluid, made by dilute hydrochloric acid under diethyl ther, yielded bright red ethereal solutions showing absorption maxima, when acidified, at 259–62 mμ, 337–42 mμ and 460–70 mμ. Solutions deposited dark red, somewhat unstable, needle-like crystals soluble in benzene, chloroform, acetone, methanol, ethanol, and concentrated sulphuric acid, less soluble in carbon disulphide and light petroleum and slightly soluble in water and hexane. They give a bright reen colour with ferric chloride, and in acid solution re unaffected by hydrogen peroxide, but are rapidly and reversibly decolorized by hydrosulphite. If partitioned between diethyl ether and water, the igment is red and epiphasic when acidified, purplish and hypophasic in the presence of alkali. Neutral or lkaline solutions are unstable. These properties indicate naphthaquinones.

Chromatography is difficult; most of the pigment tered on columns of calcium carbonate, magnesium licate, and to a lesser extent on silica gel, yielding urplish, brownish or black products and eluates with varying absorption characteristics. On powdered ellulose columns (tried at the suggestion of Prof. C. H. Hassall[2]), slow development with light petroleum or enzene produced chromatograms with three or more zones, yielding unstable eluates showing one or more of the above absorption bands, sometimes with varying number of additional maxima between 30 mμ and 400 mμ. Eluates which showed no additional maxima on the first chromatographing usually d when re-chromatographed. The additional maxima disappeared when the solutions were warmed. More rapid development with diethyl ether usually produced chromatograms with a single homogeneous orange zone showing three absorption maxima close to those of the crude extract. Sometimes two zones ppeared, the main one similar to the last, and a much smaller purple zone, which left the column in cid ethanol as an orange solution. Paper chromatography of a crude extract from an individual provided by the Zoological Society of London, recently performed by Dr. T. W. Goodwin, confirmed the instability of the main orange pigment and showed that it changed on the chromatogram to a purple pigment with an absorption maximum in the visible, at about 480 mμ. The latter is eluted from the paper with acid ethanol only with difficulty, while the original pigment is easily eluted with diethyl ether.

The main pigment, purified by chromatography and re-crystallization, shows absorption maxima in acidified diethyl ether at 263–64, 337–39, and 462–63 mμ. It melts at 223° C., sublimes at about 200° C., and does not fluoresce in the ultra-violet in ethereal solution.

Pigment is present in the form of spheroids in the podia, radial water vascular canals, gut wall, axial complex and cœlomic fluid. Some are enclosed in amœbocytes[3], others are free in the tissues, suggesting an origin from amœbocytes. Some pigment is present in the gut wall, in the form of much more minute granules or droplets. The gonads, at least during the summer, contained none of this pigment except in amœbocytes. In the amœbocytes of the cœlomic fluid a reduced precursor of the pigment appears to exist[3].

Much of this work was done in the Zoology Department of the University College of the West Indies, the spectrophotometer being provided by the Rockefeller Foundation. A full account is being prepared.

An Ecdysial Membrane in the Locust Cuticle

Passonneau and Williams[1] have described in the developing cecropia silkworm an 'ecdysial membrane' situated between pupal and adult cuticles. Richards[2] has studied the fine structure of this membrane, but was unable to demonstrate clearly its nature and origin.

A similar membrane has been found between new and old cuticles of the locust *Schistocerca gregaria* at the time of moulting from nymph to adult and at all the preceding nymphal moults. Its origin has been studied in successive stages of the nymphal-adult moult. No trace of the membrane is seen until after the retraction of the epidermis from the nymphal cuticle, when a few of the innermost laminæ of the endocuticle show properties different from those of the outer laminæ. They are sudanophil, and become detached from the dissolving endocuticle. They do not dissolve, and although at first separate from each other, later become adherent to form a discrete compact membrane. There seems no reason to doubt that the ecdysial membrane represents an innermost sheet of endocuticle which is in some way protected from the action of the moulting fluid.

This conclusion has been verified by subjecting, at different developmental stages, pieces of the last nymphal cuticle to the action of extracted moulting fluid. In the earlier stages, in which the endocuticle has not reached its full thickness, the entire endocuticle dissolved. But in later stages, including those before as well as after retraction of the epidermis, a discrete ecdysial membrane became visible after solution of the remainder of the endocuticle.

The isolated ecdysial membrane is resistant to the action of cold concentrated mineral acids, but dissolves in them readily after treatment with diaphanol. Tests on frozen sections indicate the presence of sterols and of protein, and the isoelectric point of the membrane, about *p*H 5·8, is not changed by the action of the moulting fluid. As a result of experience with the cuticle of *Periplaneta*[3], these observations suggest that the endocuticular laminæ constituting the ecdysial membrane are stabilized, like the outer layers of the cuticle, by impregnation with a lipoprotein complex. The protein moiety is protected by its association with the sterol, and is therefore not removed by the action of the moulting fluid.

Whether the ecdysial membrane has any functional significance is not clear; but its formation may be dependent on the fact that at the time when endocuticle secretion is declining preparatory to ecdysis the epidermis is already in a state of preparation for the formation of the sterol-containing outer part of the new cuticle, so that the last-formed portion of the endocuticle comes to contain material destined primarily for the new cuticle.

This work forms part of an investigation into the locust cuticle carried out while holding a senior research award of the Anti-Locust Research Centre. A full account will be given in due course.

A Technique for measuring Structural Features of Plant Epidermis using Cellulose Acetate Films

IT is often difficult to peel off areas of plant epidermis which are large enough for accurate determinations of mean cell size and stomatal distribution. Buscalioni and Pollacci[1], and Long and Clements[2] have described a method for counting stomata using collodion films; but these were found to be sometimes difficult to remove from a treated leaf, and to tend to give poor images of epidermal cells because they become opaque in the presence of water. Recently, Bennett and Furmidge[3] have recommended a technique for the study of the distribution of deposits and organisms on plant surfaces using impressions on cellulose acetate or gelatin; structural features of epidermis from some curved surfaces and 'savoyed' leaves, however, cannot readily be observed by this method. An additional technique devised here for the measurement of epidermal cells appears to overcome the disadvantages of the above-mentioned methods for this purpose.

A quick-drying coloured solution of cellulose acetat is applied to the plant organ from which measurements are required. When the dry film is removed i bears an impression of the sculpturing of the epidermis so that areas which were above lateral cel walls are thicker, and thus appear darker, than th rest of the film when viewed by transmitted light The cellulose acetate film seen through a microscop therefore closely resembles the structural features o peeled epidermis.

2 gm. of cellulose acetate and 0·7 gm. night blu or crystal violet are dissolved in 100 ml. acetone The solution is painted on the epidermis with a camel hair brush which is kept immersed in acetone whe not in use. The film dries in a few seconds, and, afte flooding with a strong solution of detergent, can b lifted from the plant. Films are more easily remove from large areas and whole leaves if treated materia is placed in an oven and allowed to wilt before applying detergent. The stripped film is mounted on slide with the surface which faced the plant uppermost, and dried by dabbing with filter paper; it i then immediately ready for viewing dry. Larg areas of film should be stuck to the slide. Whe observed with an orange light source, films coloure with night blue give almost black images which ar very suitable for photographing on panchromati film.

A cellulose acetate film takes a few seconds t prepare, and gives a permanent record from whic measurements can be made at leisure (Fig. 1). Ther is no risk that the cells will shrink during the preparation, or that the picture will be confused by th presence of underlying mesophyll cells—two faults c the 'peeling' method. The technique is suitable f leaves, petals and other organs of many plants excep those which are densely covered with hairs. Not a plants that were tested gave equally well-define films; but satisfactory records of cell size an

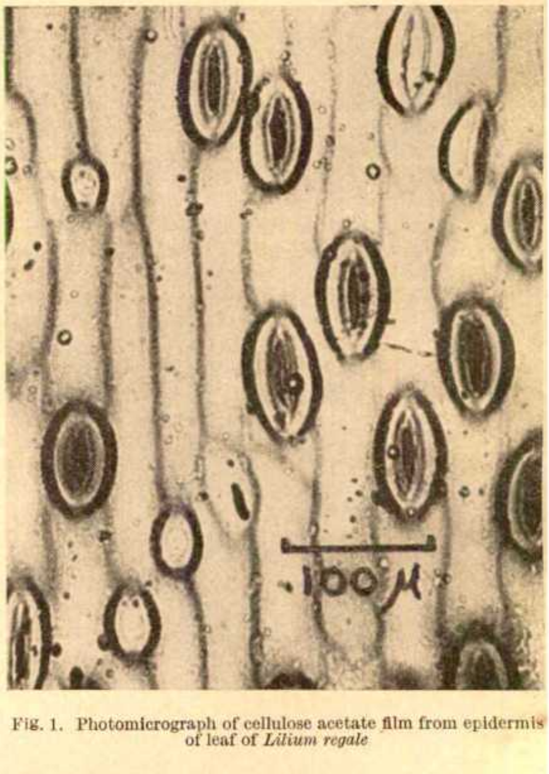

Fig. 1. Photomicrograph of cellulose acetate film from epidermis of leaf of *Lilium regale*

stomatal number were obtained from many species hat were unsuited to the 'peeling' method.

Possible Use of Sorbic Acid as a Preservative for Corn Silage

MANY types of preservatives such as ground ereals, sugar beet pulp and molasses are employed to reserve silage in the best possible condition. These reservatives are high in fermentable carbohydrates which help to stimulate lactic acid fermentation. Some armers have been using hydrochloric and sulphuric acids to control the protein breakdown which gives an unpleasant smell to silage. The use of ground ereals is uneconomical. Beet pulp and molasses are vailable only in certain places and usually in limited upply. Inorganic acids like hydrochloric or sulphuric re strong acids, and, from the point of view of armers, they have been difficult to handle and distribute in the silo. Likewise, such acids produce deleterious effects on the digestive system of farm nimals. Virtanen[1] reported that there is a need or a suitable and cheap organic acid for silage-naking with acids.

In recent years sorbic acid, a mild organic acid, as been used extensively as a fungistatic agent in he food-processing industries. In cucumber fer-nentation, 0·1 per cent sorbic acid controlled yeast cum formation without interfering with the normal nd desired fermentation by bacteria which produces actic acid[2]. It has also been shown that the sorbic cid is less toxic and a better preservative than odium benzoate[3,4].

Wide-mouth glass jars were used as the experi-nental silos. The corn silage was prepared in them s it would have been in the regular silos. Prior to nsilage, corn plants were chopped into small pieces nd were 'pitched' in the 'silos'. Each layer was acked well. Water was sprinkled on the top of each ayer in the case of untreated (control) silos which vere again packed to remove the air pockets. In the ase of treated silos, sorbic acid solutions were prinkled instead of water. Concentrations of 0·3, ·2, 0·1, 0·05 and 0·025 per cent of sorbic acid on an bsolute weight basis were prepared in tap-water nd were sprinkled on the top of each layer of the nsilage material. Sorbic acid was kindly furnished y the Carbide and Carbon Chemicals Co., New York. ome of the silos thus prepared were covered with ir-tight lids and the remainder were uncovered. The xperiment was conducted in triplicate. Following nsilage and treatments, the silos were stored in card-oard boxes at room temperature for a period of five nonths. After five months, they were weighed to etermine the percentage loss in weight and were pened to inspect the microbial growth on the urface.

It was noticed that the silage was less affected y mould than untreated silage. Higher concentra-ons of sorbic acid were more effective in controlling the mouldy growth than the lower concentrations. However, the concentration 0·1 per cent was quite as effective as that of 0·3 per cent.

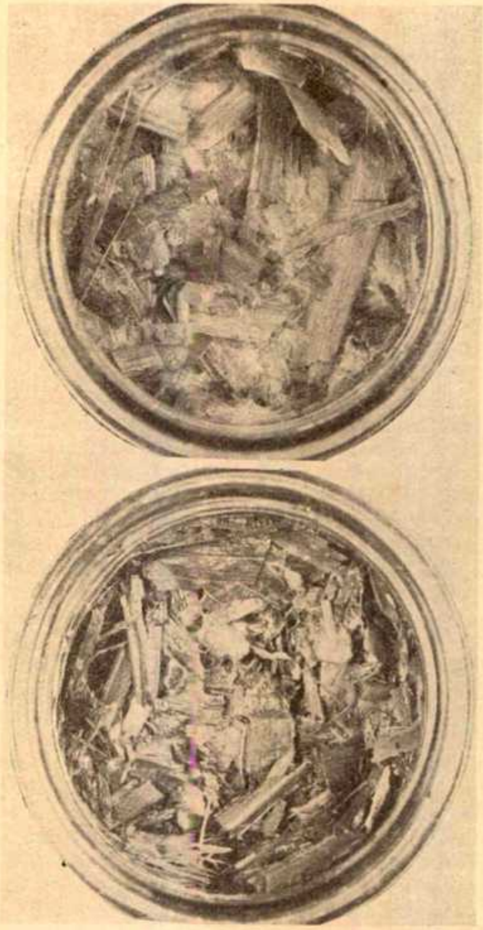

Fig. 1. Top, Growth of mould in profusion on the surface of silage sprinkled with water; bottom, very slight growth of mould on the surface of silage sprinkled with 0·1 per cent sorbic acid solution

Fig. 1 (top) shows the profused growth of mould on the top layer of the silo which was sprinkled with water and Fig. 1 (bottom) shows very little or no growth on the top layer of the silo which was sprinkled with sorbic acid solution at the concentration of 0·1 per cent. Mouldy growth on the silage gives bad odour and flavour.

The occasional spraying of the silage material with harmless sorbic acid solution (0·1 per cent) while the silo is being filled will preserve silage in good physical condition. At the same time a larger percentage of proteins will be preserved which ultimately will be recovered in milk and in meat. The *p*H of sorbic acid (0·1 per cent) solution is 3·6. The preservation of the silage material at such low *p*H produces silage of high quality.

Growth-promoting Effects of Ethylenediamine Tetra-acetic Acid

THE recent communication by Heath and Clark[1] prompts us to present some of our observations of presumed plant hormone effects of the chelating agent ethylenediamine tetra-acetic acid. Reference to these observations was made in a review on the application of chelation to agriculture[2]. Our interest in this problem developed from observations, made in the summer of 1953, on massive growth response to ethylenediamine tetra-acetic acid by sunflower plants in water culture; metal complexing effects in the nutrient medium were involved, but there was also evidence of a direct effect of ethylenediamine tetra-acetic acid itself on growth.

To investigate possible growth-regulator effects of ethylenediamine tetra-acetic acid, a series of experiments on straight growth of hypocotyl sections of etiolated white lupin seedlings was undertaken late in 1953. Sections 2 cm. long were cut from central portions of hypocotyls 6–7 cm. in length (one section per seedling) from seedlings germinated in the dark at 24°–26° C. under a continuous tap-water spray. For each treatment twenty-five sections were floated on the appropriate solution in a large Petri dish which was then stored in the dark at 25° C. All solutions were made up with de-ionized water without added nutrients. Measurements were made after 24 hr. In preliminary experiments, all treatments included indole acetic acid at $1 \times 10^{-5} M$. It was found that either indole acetic acid at this concentration or disodium ethylenediamine tetra-acetate at $5 \times 10^{-5} M$, or both in combination, caused increases in elongation and water uptake of about the same magnitude, 30–50 per cent. In contrast with the studies using the wheat coleoptile[1], in which growth of controls on water alone gave elongations of about 80 per cent in 19 hr. at 25° C., the lupin hypocotyl sections elongated only about 10 per cent in 24 hr. at the same temperature. The relative magnitude of effects attributable to these compounds thus appears greater with the lupin material than with wheat, presumably because of a lower content of native hormone in this tissue.

When hypocotyl sections were floated on solutions of disodium ethylenediamine tetra-acetate substantial increases in both length and water uptake were observed at concentrations of 3×10^{-4}, 1×10^{-4} and $5 \times 10^{-5} M$, with maximum increases of more than 50 per cent occurring at either 5×10^{-5} or $1 \times 10^{-4} M$. Addition of pH 5 phosphate buffer to the solutions did not influence these results. With disodium ethylenediamine tetra-acetate at $5 \times 10^{-5} M$, respiration was stimulated to the extent of a 50 per cent increase in oxygen uptake.

The experiments with disodium ethylenediamine tetra-acetate are presumed to demonstrate effects of exposure of the plant part to uncomplexed chelating agent, so that responses observed are attributed to its action within the tissues. To study the response to complexed chelating agent in the medium, experiments were carried out with the iron chelate, ferric disodium ethylenediamine tetra-acetate, which at most physiological hydrogen-ion concentrations is the most stable known chelate of ethylenediamine tetra-acetic acid. At $10^{-4} M$ ferric disodium ethylenediamine tetra-acetate, there was a 10 per cent decrease in length and 15 per cent loss of water from the tissues, and more gradual but continued decreases at higher concentrations. Respiration was stimulated about 10 per cent by $5 \times 10^{-5} M$ of the ferric disodium compound, as contrasted with 50 per cent stimulation by the disodium compound at this same molar concentration. It seems evident from these results that growth-stimulating effects of ethylenediamine tetra-acetic acid are associated only with the addition of uncomplexed chelating agent to the growing medium.

The association of growth-promoting effects with uncomplexed ethylenediamine tetra-acetic acid in the medium, but not with the iron chelate, can be interpreted as supporting the concept of growth promotion by removal of calcium from the cell-wall structure. This would presume that uncomplexed ethylenediamine tetra-acetic acid, in passing through the cell wall, forms a chelate with calcium removed from the wall structure, which is thereby enabled to expand.

A further observation of hormone effects exerted by ethylenediamine tetra-acetic acid has been seen in epinastic response of soybean leaves on plants in solution cultures supplied with disodium ethylenediamine tetra-acetate at concentrations of $6 \cdot 7 \times 10^{-5} M$ or higher. The response characteristically took the form of an opening of the angle between petiole and stem and twisting of the leaflets through angles ranging from 90° to 270°.

This investigation will be presented for publication in more detail in a subsequent issue of the *Contributions from Boyce Thompson Institute*. It was supported by grants from the Refined Products Corp., Lyndhurst, N.J., and by Versenes Inc., Dow Chemica Co., Framingham, Mass.

Seed-coat Structure of Ethiopian 'Rape'

SAMPLES have been obtained of seed described a Ethiopian 'rape', imported into Europe for oil extraction. Plants grown from the seed corresponded with specimens in the Kew Herbarium named *Brassica integrifolia* (West) O. E. Schulz var. *carinat* (A.Br.). This plant is cultivated in Ethiopia and adjacent north-east African territories. Most taxonomists regard this species as a mustard, and som include it in the *B. juncea* complex which contain a number of mustards of commercial importance.

Fig. 1 is a drawing of a cross-section of the testa All layers characteristic of the cruciferous seed-coat are present. The uneven height of the palisade cells i responsible for a distinct reticulation which is show by the whole seed and, also, by surface preparation of the palisade layer. The subepidermal layer although not so distinct as that of *B. nigra*, is ofte quite obvious. So far as the mustards of commercia

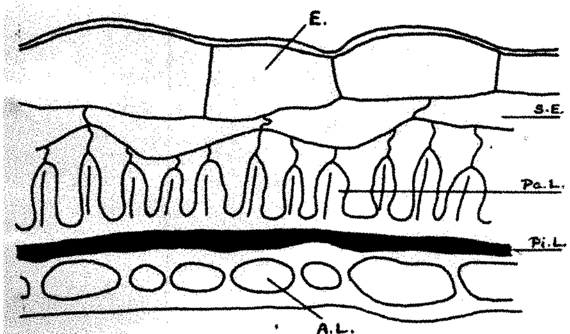

Fig. 1. Drawing of cross-section of testa of Ethiopian 'rape' (× 380). *E*, Epidermis; *S.E.*, subepidermis; *Pa.L.*, palisade layer; *Pi.L*, pigment layer; and *A.L.*, aleurone layer

mportance are concerned, the seed-coat structure of this Ethiopian plant would seem to correspond most closely to that of sarepta or brown mustard *B. besseriana* Andrz). In this connexion, it is interesting to note that, like the Ethiopian species, sarepta mustard is often placed in the *B. juncea* complex.

Although it may not be possible to identify this Ethiopian plant on testa structure alone, the presence of a well-defined epidermis, subepidermis and palisade ayer, consisting of comparatively large cells and with well-marked reticulations, serves to place it in he *B. juncea* complex. Identification on seed-coat tructure is useful in cattle cake analysis, and cattle ake described as Ethiopian 'rape' has been found o contain testa fragments with a structure similar o that described in the previous paragraph.

It is intended to publish the details of this investigaion elsewhere. I am indebted to the Incorporated Oil eed Association and Salamon and Seaber (consulting nalytical chemists) for the supply of material and lso the Central Research Fund of the University of London for the loan of certain apparatus used in this work.

Nitrogenous Compounds in Plant Xylem Sap

THE predominance of organic nitrogenous compounds in the tracheal sap of apple trees[1] implies hat incoming inorganic nitrogen is largely converted to organic form in the root system. The transpiraon stream then carries to the shoot a mixture of mino-acids and amides among which aspartic acid, sparagine and glutamine are quantitatively the ost important.

That these phenomena are not unique to apples as been shown by chromatographic examination of ylem sap extracted from shoots of a range of cotyledons, monocotyledons and gymnosperms. he plants used were all selected as capable of yielding xylem sap[2]. However, not all species examined ere woody shrubs or trees, as extension[3] of the sap traction technique rendered possible the sampling a considerable number of herbaceous species.

Nitrate was present in saps of less than half the species tested and usually in only trace amounts. In all cases, however, whether nitrate was detectable or not, a range of organic nitrogenous compounds was present. Though no quantitative measurements of individual compounds were made, it was clear that the substances detected in each case would have largely accounted for all the nitrogen in each sap sample.

With most species, either asparagine or glutamine was quantitatively the most important individual compound, glutamine occupying this role in 75 per cent of the species tested. Usually, however, both amides as well as aspartic and glutamic acids were present as well as a range of other amino-acids in lesser amount. In this category, alanine, serine, threonine, methionine and/or valine, and leucine were most commonly present. Examination of some hydrolysed sap samples has revealed the appearance of further compounds, mainly glycine, cystine and cysteic acid, implying the presence of a peptide-like substance in the sap. There was thus in the composition of many samples a striking similarity to the range of compounds already described as present in apple sap[1].

Citrulline was present in the xylem sap from species of twenty-nine families. This compound has not previously been widely recorded in plants; but it has been found in *Alnus*[4] and members of the Betulaceae[5]. While this compound was not widely distributed among the species studied in the present work it was of considerable importance in a number of species of the following genera: *Juglans, Alnus, Nothofagus, Annora, Persea, Diospyros* and *Chamaecyparis*. Citrulline was not detected in any monocotyledon.

Allantoin and/or allantoic acid were present in xylem sap from members of twenty-three families. These compounds have long been recognized[6] as plant constituents; but interest in them as storage and translocatory compounds has arisen only lately[5,7]. In some of the species studied in the present work these compounds were present in low concentration; but in some species of the genera *Persea, Acer, Aesculus, Alectryon* and *Cobaea* allantoic acid was a major constituent of the xylem sap. Neither of these compounds was detected in any gymnosperm and in only one monocotyledon (*Arundinaria*).

It is apparent that the xylem translocation of organic nitrogen is not a phenomenon peculiar to apples. Partial or complete assimilation of inorganic nitrogen must occur before it passes into the transpiration stream. It is of interest that the presence of organic phosphorus compounds has recently[8] been detected in a plant xylem sap.

The course of assimilation of nitrogen in the root must vary just as the compounds in the sap vary, and any description of this process must account for the importance of glutamine and/or asparagine as well as the importance in some species of citrulline or allantoic acid. It is not clear whether the compounds present in tracheal sap are early products from the incorporation of inorganic nitrogen into organic compounds or are products of breakdown of storage proteins. It may be that they result from both processes.

Whatever their origin, it is in the form of these organic nitrogenous compounds that the shoot receives nitrogen from the root system and it is these which are available to the shoot for its further metabolism.

Attention has recently been directed[9] to the metabolic interrelations of root and shoot, but little is known concerning any specific requirement of the shoot for nitrogenous compounds. It may be that all the shoot requres is a bulk supply of inorganic or organic nitrogen, or it may be that all or some of the specific compounds present in xylem sap are essential for shoot development.

Alloploid Nature of Okra, *Abelmoschus esculentus* (L.) Monech.

Abelmoschus esculentus (L.) Moench. (= *Hibiscus esculentus* L.[1]), commonly known as lady's fingers, okra or bhindi, is an important vegetable crop cultivated in the different countries of the world. The chromosome number of this species has been variously reported as $2n = 130$ [2] and $2n = 72$ [3]; in a number of varieties examined by us[4], the chromosome number was invariably found to be $2n = 130$.

Pal, Singh and Vishnu Swarup[5] described from India a new species, *Abelmoschus tuberculatus* Pal et Singh, related to okra. The chromosome number of this wild species was determined by us[4] to be $2n = 58$.

Meiosis and seed setting in *A. esculentus* ($2n = 130$) and *A. tuberculatus* ($2n = 58$) were normal. The F_1 hybrids ($2n = 94$) obtained from reciprocal crosses between these two species were totally sterile. Chromosome pairing in these hybrids appeared to be interesting from the phylogenetic point of view. Out of 122 pollen mother cells which could be very clearly analysed, 105 showed the chromosomal association, $29^{II} + 36^{I}$, 13 showed $28^{II} + 38^{I}$ and 4 cells showed $27^{II} + 40^{I}$. The most frequent association, $29^{II} + 36^{I}$, strongly suggests that the 65-chromosome cultivated okra is an alloploid comprising two genoms, one with 29 and the other with 36 chromosomes. The former genom is homologous with that of *A. tuberculatus*; the latter genom may be related to any among the species of *Abelmoschus* having $n = 36$ chromosomes.

Among the *Abelmoschus* species of which chromosome numbers have so far been reported in the literature, three have $n = 36$ chromosomes: *A. ficulneus* (L.) Wt. and Arn.[6] (= *Hibiscus ficulneus* L.), *A. moschatus* Medik. (= *Hibiscus abelmoschus* L.[2]), and *Hibiscus esculentus* var. Blue Long *A* [3]. *A. tuberculatus* seems to be the only species so far for which the chromosome number, $2n = 58$, is certain.

A chromosome number approaching that of *A. tuberculatus* was reported for *Hibiscus manihot* ($2n = 60$)[3,7]; however, Skovsted[2] reported $2n = 66$ and Kuwada[8] $2n = 68$ chromosomes for this species. Teshima[3] observed all the chromosomes as univalents, during meiosis, in the F_1 hybrid (*H. esculentus* var. Blue Long *A*, $n = 36$ × *H. manihot*, $n = 30$), and in the F_1 hybrid (*H. esculentus* var. Dwarf Prolific, $2n = 126$–134, × *H. manihot*, $2n = 60$) Chizaki[7] reported the formation of 0–7 pairs during meiosis. Recently, Prof. Kuwada of the Kagawa University, Japan, observed at meiosis in the F_1 hybrid of *A. esculentus*, $2n = 124$, with *A. manihot*, $2n = 68$, the formation of 0–7 bivalents (personal communication). The cytological features of these hybrids are thus distinct from those of the present one, namely, *A. esculentus* × *A. tuberculatus*.

We have so far not met with a form of *A. esculentus* with $2n = 72$ chromosomes, the number reported for the variety Blue Long *A* of this species by Teshima[3]. Should Teshima's observations be confirmed, *A. esculentus* would appear to comprise two chromosomal races, $2n = 72$ and $2n = 130$. While it would then be interesting to study the evolutionary origin of the form with $2n = 72$ chromosomes, it would appear from the present results that cultivated okra (*A. esculentus*, $2n = 130$) may have originated through hybridization between a 29-chromosome and a 36-chromosome species of *Abelmoschus* followed by chromosome doubling in the resulting hybrid.

In this context, it is interesting to note that the F_1 hybrid, *A. ficulneus* ($n = 36$) × *A. tuberculatus* ($n = 29$), studied by us was totally sterile and formed on an average, 1·63 chromosome pairs per pollen mother cell, the frequency being as follows:

No. of pairs per pollen mother cells	0	1	2	3	4	5	6	7	
No. of pollen mother cells	27	14	18	7	8	1	2	1	(= 78

Experiments are under way to synthesize an $n = 65$ chromosome form through chromosome doubling in this hybrid.

Vavilov[9] has suggested, on the basis of phytogeographical studies, an Abyssinian origin for *A. esculentus*. Further studies on the world distribution of *Abelmoschus* species, especially in the Abyssinian region and on their cytogenetic affinities would be helpfu in elucidating the problem.

We are grateful to Dr. B. P. Pal and Dr. S. M Sikka for encouragement and helpful criticism durin the course of these investigations.

Protective Coloration and Animal Behaviour

Procryptically coloured insects may resemb objects occurring in their environment very closely[1] thus leaf-mimicking butterflies may bear markin resembling veins, holes eaten by phytophagou insects, mildew, etc. This has been held by son authors to invalidate the theory of natural selectic as applied to the phenomena of mimetic protective coloration, since it is argued that avian predators are unlikely to achieve the refinements of discrimination possible for human observers, who are themselves often deceived.

Carter[2] has supported the latter part of this criticism, and has proposed an alternative view. He nterprets the work of Lorenz[3] as showing that birds respond to only a few of the available visual characters of the objects which they perceive: "The conclusion of recent studies of bird behaviour is that very generally, at any rate in those situations . . . in which recognition of the object leads to some course of action, a bird recognizes an object not by its general appearance, as we do, but by some simple and usually single feature possessed by the type of object to which it belongs. This feature may have very little to do with the general appearance of the object". Carter admits that simplicity is not found in studies of problem-solving behaviour, but dismisses such situations as artificial. He proposes that the refinements of imitation found in Nature may have been achieved through selection pressures mediated by a number of different species of predator, each responding nnately to distinct, individual features of the model objects. Such an accumulated selection pressure, contributed by a diversity of sources, would be capable of mediating the production of accurate facsimiles of the superficial appearances of the model objects to which the predator's responses were originally directed. This suggestion has been incorporated nto at least one general discussion of allæsthetic characters[4].

Carter's proposal involves three assumptions: 1) responses of birds to prey-objects are inborn and igidly determined; (2) inborn responses are given o releasing stimuli which commonly possess only one or a very few valent features; (3) different features f the same releasing object may be valent for different pecies of passerine.

It is likely that avian responses to prey-objects are primarily inborn; but the fine details of the orientation of attack[5], and the choice of object[6], may be rapidly modified by learning processes, and it is certain that many features of a variety of edible objects must acquire valence for an experienced predator. The releasing stimuli for some intraspecific responses are simple[7], and possess a few valent features only; but many characters of an object, or class of objects, may be valent for the release of a single unconditioned nterspecific response[8]. The third assumption has not been specifically tested; but experiments comparing the releasing value for passerines in three different families (Fringillidae, Emberizidae and Paridae) of three characters present in a two-dimensional eye-like pattern have not supported it, though they offer no positive disproof[5].

An experienced bird, searching a habitat containing cryptic prey, or confronted with a Batesian or Mullerian mimic, gives a response which may have been appropriately modified as the result of a previous learning process[6,9]. To explain the accuracy of a particular cryptic or mimetic resemblance it is necessary to show that at least one species of predator can achieve discrimination learning of an equivalent refinement. This ability has been demonstrated by de Ruiter in the avian predators of stick-like caterpillars[10], and its converse, for the case of wasp-mimicry, by Mostler[9]. If the responses of the birds are susceptible to learning processes, the nature of the original unconditioned releasing mechanisms in inexperienced predators is largely irrelevant to the selection process.

Certain protective resemblances have been shown to utilize the inborn responses of predators. The eyespot patterns of many insects are exhibited by special displays (Blest, A. D., in preparation) and they release escape behaviour from small passerines. The responses of the latter are almost certainly independent of previous experience of eye-like objects, and are quite certainly wholly independent of previous experience of the birds' own predators[5]. Repeated encounters with a spotted and displaying insect may either reinforce avoidance behaviour, or cause it to wane to extinction. At no point would discrimination learning appear to enter into the situation. It is possible that the hypothesis proposed by Carter might apply to cases of this type, but the existing work on animal behaviour fails to indicate any necessity for such special postulates, either to account for the evolution of intimidating patterns, or procryptic resemblances and orthodox Batesian and Mullerian mimicry.

It remains to re-emphasize that statements concerning the sensory capacities of animals, or their power to achieve sensory discriminations, based on experiments involving the elicitation and measurement of responses from whole organisms, are only meaningful in terms of the precise experimental situations employed[7]. This qualification is often ignored in the more general literature.

Fossil Frogs from a Lower Cretaceous Bed in Southern Israel (Central Negev)

THE presence of fossil frogs in Israel was discovered in January 1954, when several specimens were found in the Ramon erosion cirque, in the central Negev, about 80 km. south of Beer-Sheba.

The geological formations exposed in the cirque cover the periods from Middle Triassic up to Cenomanian. The fossil frogs were found in a lacustrine continental deposit. The profile of the place is as follows:

Formations	Depth (m.)
Upper basaltic flow	10·00
Lacustrine deposit (Varvy silt containing the fossil frogs together with plant remains)	1·50
Laterite, red-purple	10·00
Tufa, greyish-green	10·00
Lower basaltic flow	5·00
Basal Lower Cretaceous conglomerate	0·50

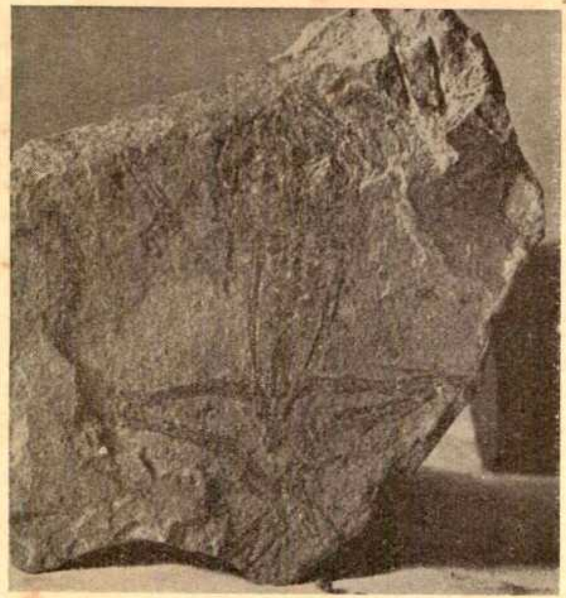

Fig. 1

The age of the formation containing the frogs was determined as Lower Cretaceous, the many plant remains, among them *Weichselia reticulata*, furnishing a fairly safe clue to the period of fossilization. Additional evidence points to an age ranging between Aptian and Albian. In 1955 and 1956, two more visits to the site were made and so far several dozens of fossil frogs and one tadpole have been discovered.

The fossil material underwent various stages of limonitization. This process brings out the whole skeleton of the frogs preserved as an imprint in the soft rock which is secondarily filled with limonite, or as petrified osseous matter.

A first survey revealed the occurrence of three types of frogs. Among them one exhibits some pelobatid features (Fig. 1), such as a distally enlarged sacral transverse process. A second type of fossil frog does not show this enlargement and has a rather pointed head, and teeth on the maxillary bone.

The tadpole (Fig. 2) shows the caudal fin fold preserved as a fairly distinct imprint, and, strangely enough, a series of about twenty free vertebral elements extending through body and tail up to its tip. This state of matters fits nicely with the recent discovery of I. Griffiths[1], who mentions the differentiation of free vertebræ in the larval tail of the recent pelobatid *Megophrys major*. The fossil tadpole found here seems to be the earliest one known so far, since adults only have been described from earlier formations, as, for example, the well-known specimens from the Jurassic of Lerida in Spain and from the United States.

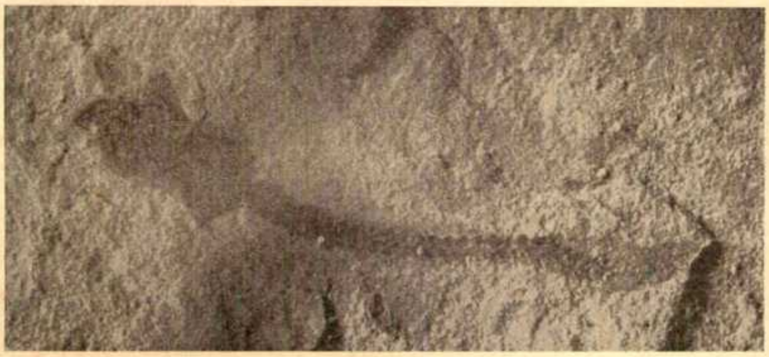

Fig. 2

The presence of free vertebræ in this tadpole contrasts sharply with the differentiation of a typical urostyle in all the adult specimens found, which possess, on the whole, modern anuran features. The presence of free caudal vertebræ in the tadpole seems to indicate that the formation of the adult urostyle differed from that of recent frogs.

The material is under study at the Department of Zoology of the Hebrew University in Jerusalem, under the supervision of Prof. G. Haas. A detailed study will be published elsewhere.

Structure of Cupric Salts of Monocarboxylic Fatty Acids

IN a previous communication[1] on the structure o cupric formate, acetate and propionate, we concluded that the latter two compounds, both i organic solvents and in crystalline state, consist o dimeric molecules, $\mathrm{Cu}_2(R\mathrm{COO})_2.X_2$, X being a solvent molecule, in which the copper-to-copper linkage might be expected. The following facts were then assume to support the above conclusion : (1) the acetate an propionate show an absorption band of a special kin at about 80×10^{13} c./s., which was ascribed to th possible copper-to-copper linkage ; (2) the absorptio of the special kind is greatly polarized along the direction binding the two copper atoms within a molecule This is the reverse of the polarization property wit the band at 43×10^{13} c./s.

Using the above criteria, we have recently examine the structure of cupric butyrate monohydrate an non-hydrate, valerianate monohydrate, capronate an caprylate. All these in chloroform or ethyl alcoh are found to show absorption spectra which are closel similar to those of cupric acetate and propionate i solution, showing an absorption band of the specia kind at about 80×10^{13} c./s. The dichroism in th visible and ultra-violet of the salts has been determined quantitatively by the microscopic method[1] The crystals of the above compounds show absorption bands a 43 and 80×10^{13} c./s. beside strong absorption in the shorte wave-length regions. The polarization of the band at abou 80×10^{13} c./s. is found to b the reverse of the polarization the band at about 43×10^{13} c./ These relationships bear a clos resemblance to those of cupri acetate and propionate, suggestin the existence of similar dimeri molecules.

It was also found that th water of crystallization does n cause any essential discrepancy i the dichroism. It is most likely, therefore, that the linkage, if any, of the water molecules to the copper atom is not strong in the above type of compounds.

Determination has also been made of infra-red spectra in 'Nujol' of the above compounds, including the cupric formate, acetate and propionate. All of them except the formate show in the region between 1,500 and 2,000 cm.$^{-1}$ and only one absorption at about 1,600 cm.$^{-1}$, which is rather sharp and due to the anti-symmetrical vibration of the COO^- group[2]. This is believed to be further evidence for the existence of the dimeric molecules in the above compounds. The formate tetrahydrate, which was found to involve no dimeric molecules[1], does not show the absorption at the above frequency, although the formate ions are linked to the copper atom. Instead, cupric formate shows a corresponding COO^- absorption at lower frequency, which is considerably broader than the sharp band with the other cupric salts.

Cupric palmitate and stearate in acetic anhydride have been found to show ultra-violet absorption spectra which are closely similar to that of cupric acetate. The infra-red spectra in 'Nujol' have also been measured with the two compounds ; they show one sharp absorption at about 1,600 cm.$^{-1}$. This is identical with the frequency shown by cupric acetate. These facts suggest that the two compounds may also contain the dimeric molecules.

All the above facts lead us to the conclusion that cupric acetate, propionate, butyrate, valerianate, capronate, caprylate, palmitate and stearate contain the dimeric molecules both in their crystalline state and in organic solvents. It is suggested further that the cupric compounds with the homologues of monocarboxylic acids from acetic up to stearic acid consist of dimeric molecules.

Preparation of Tritium-labelled Derivatives of Benzoic Acid

ISOTOPE exchange methods have long been employed for the study of the reactions of hydrogen atoms attached to aromatic ring-systems, and also, o a limited extent, for preparative purposes[1,2]. Most of the preparations described in the literature were carried out with water of a comparatively low deuterium content. While these methods are not suitable for the preparation of compounds having a high D : H ratio in the labelled groups, they are apart from questions of economy in the use of ritium), in principle applicable to the preparation f tritium-labelled materials, since the tritium content of the starting material (water) is normally much less than 1 per cent. The present communication describes a simple, rapid and direct method for the labelling of *p*-nitro benzoic acid at very high specific activity, with considerable economy in the use of radioactive material. It is also suitable for use with deuterium at high abundance. The two isotopes can, with advantage, be combined in the same preparation : analytical procedures (for example, infra-red spectroscopy) are thereby considerably facilitated.

Tritiated water at specific activities in excess of 220 mc./ml. being a relatively expensive material, it is essential to introduce as little hydrogen as possible from reagents. Unfortunately, the nitro-group has a very marked inhibiting action on the exchange, necessitating the use of very concentrated sulphuric acid (over 85 w per cent)[3]. Other acids, for example, phosphoric, are ineffective[4] or otherwise unsuitable, for example, perchloric. This difficulty is overcome by the use of vapour-phase exchanges in a three-legged vessel (Fig. 1). Into one leg is placed the *p*-nitro benzoic acid (1 gm.), with about 0·1 gm. of concentrated sulphuric acid. Into the second leg is placed 0·6 gm. of fresh phosphorus pentoxide. These legs are then rapidly sealed off. The ampoule of tritiated heavy water (1 curie in 0·2 ml.) is opened, and dropped rapidly into the third leg, which is then sealed off. The pumping-off tube is stoppered to prevent access of atmospheric water vapour. When all the liquid water has disappeared, the vessel is partially evacuated and sealed off. The whole is then heated to 250° C. in an oven for an hour (m.p. of *p*-nitro benzoic acid, 242° C. : b.p. of 88 w per cent sulphuric acid, 250° C.). The phosphorus pentoxide acts as a reservoir for the water (moist phosphorus pentoxide exchanges its hydrogen freely with water vapour and maintains the concentration of the sulphuric acid at the right level). Infra-red analysis (via the pumping-off stem, without breaking the ampoule) indicates that, at this time, the exchange extends to about two of the four ring hydrogen atoms. Very prolonged treatment is needed to cause the remaining two to be exchanged. Published data[5] suggest that these two groups of hydrogen atoms correspond to those which are ortho and meta with regard to the carboxyl group respectively.

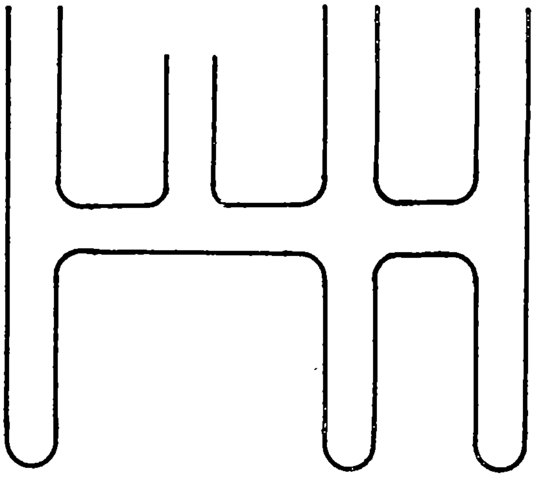

Fig. 1. Reaction vessel for the preparation of radioactive *p*-nitro benzoic acid

Neglecting isotope effects on the exchange equilibria, the radioactive yield $\left(= \frac{\text{useful activity}}{\text{total activity}}\right)$ is about 28 per cent, in the absence of chemical losses, if two ring positions are exchanged, and would be 44 per cent if all four positions came to equilibrium. Since, however, degradation and sulphonation increase with duration of the heating, the radioactive yield into purified p-nitro benzoic acid is likely to be much less than 44 per cent in the second case.

After purification, and removal of the activity from the carboxyl group, the overall yield was about 70 per cent by weight (17 per cent by activity), the specific activity being 230 mc./gm.

Further studies on the use of this material are in progress. A detailed account of the method will be published elsewhere.

A Surface Contact Microscope for the study of Cell Movements

The importance of the contacts formed by moving cells in controlling their behaviour has been clearly shown in the phenomenon of contact guidance described by Weiss[1] and in contact inhibition described by Abercrombie and Heaysman[2].

In order to study the contacts formed between cells and solid surfaces, it is possible to make use of the slight penetration of light waves into the less dense medium when totally internally reflected at a glass/water interface. The apparatus used for these studies is illustrated in Fig. 1. Light from an intense source S (compact-source mercury arc) passes through the slit T and strikes the upper surface A of the 60°-prism. A cell suspension in water is mounted between an ordinary microscope slide and a coverslip and is sealed with immersion oil on the upper face of the prism (Fig. 2). The incident light now strikes the upper surface of the glass slide at an angle greater than the critical angle and is totally internally reflected at the glass/water interface. In reality the beam penetrates the less dense medium slightly, as shown diagrammatically in Fig. 3(a). If a cell of refractive index greater than water is moving on the surface (Fig. 3(b)), those portions which make close contact with the surface of the glass will enter the penetrating beam and will scatter the light, owing to the presence of minute inhomogeneities in their structure.

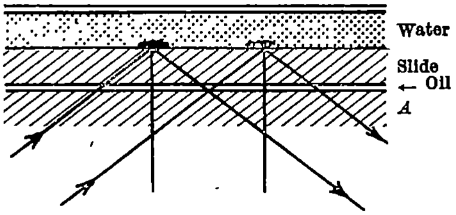

Fig. 2

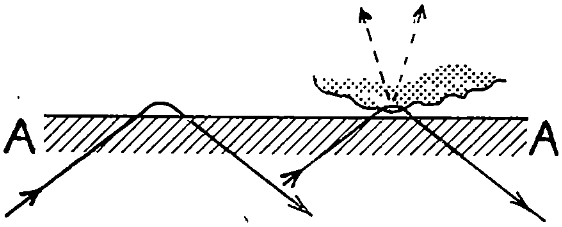

(a) (b)

Fig. 3

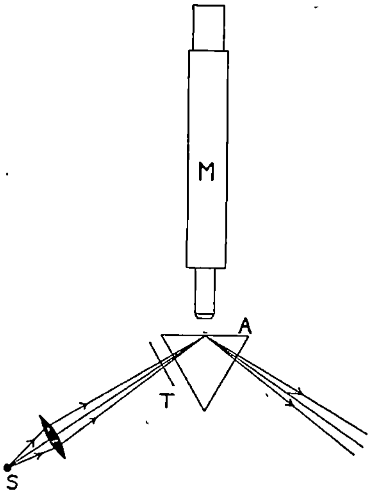

Fig. 1

When seen from above, through the microscope M, the field appears completely dark, provided that the incident light beam has been carefully shielded and the prism faces are clean. But those regions of the moving cells which are in close contact with the glass are brightly illuminated. In addition, the actual contours of the cell surface can be explored by changing the angle of the incident beam. With increasing angle, the degree of penetration of the incident beam is decreased so that the areas of the cell which are illuminated are reduced, eventually to those regions which are almost in molecular contact with the glass surface.

The effect is particularly well illustrated in the case of a filamentous mould kindly provided by Dr. R. J. Goldacre. As the mould moves forward along the glass, bright waves of light can be seen to move rapidly along its length, which are due to continuous changes in the points of adhesion between the lower surface of the mould and the glass surface. Apart from its biological application, the microscope may prove to be generally useful for the study of a number of phenomena, particularly those connected with the forces of cohesion between surfaces.

I am grateful to Prof. A. Haddow for his interest and encouragement in this work. This investigation has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the British Empire Cancer Campaign, Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

Adsorption of Uranium on Clay Minerals

In the conventional sulphuric acid leaching of low-grade uranium ores, using 50–200 lb. acid per ton of ore, considerable amounts of uranium may remain in the leach residues, especially with secondary ores where the uranium is in the hexavalent form and should be readily soluble. We have recently been studying the absorption of uranium on clay-like minerals (for example, montmorillonite, vermiculite and halloysite) to investigate the possibility that dissolved uranium may be reabsorbed by an ion exchange mechanism on the clay minerals in an ore, thereby leaving a residue relatively high in uranium despite the usual filtration and washing procedures.

In synthetic mixtures of clay, sand and a uranium mineral, simulating ores containing 0·1–0·2 per cent uranium oxide, we have been able to demonstrate that up to 0·02 m.eq. of uranium can be absorbed on 1 gm. of the above-mentioned air-dry clays under conventional leaching conditions. The results, however, are not consistent with the known cation exchange capacities of montmorillonite, etc., which may be as high as 1 m.eq. per gm. of clay, and are quite different from the values reported by Goldstaub and Wey[1], who found that 0·5–0·6 m.eq. of uranium could be absorbed per gm. of air-dried hydrogen montmorillonite from uranyl nitrate or acetate solutions. As our work was done with a sodium montmorillonite (Wyoming bentonite) in sulphate solutions, and at concentrations and clay–liquor ratios quite different from those used by Goldstaub and Wey, it was not surprising that different results were obtained; but the magnitude of the difference nevertheless seemed excessive. We therefore repeated some of Goldstaub and Wey's experiments with sodium montmorillonite, using both nitrate and sulphate media (0·57 and 0·53 per cent uranium oxide respectively), and leaving 20 ml. of solution at *p*H 1·7–1·8 in contact with 1 gm. clay for 1 hr. in each test. The results, which represented equilibrium conditions, showed a loading of 0·33 m.eq. per gm. clay with nitrate solution, in substantial agreement with the values of Goldstaub and Wey, while the figures for sulphate solution were 0·07 m.eq., being more in line with the lower values obtained in our earlier work.

Confirmation of the unusual properties of sulphate solutions was obtained by repeating the above experiments with the strongly acidic cation exchange resin, *I.R.* 120, instead of clay. The results (Table 1) are expressed for convenience in terms of an arbitrary distribution ratio, namely, uranium oxide per gm. moist resin/uranium oxide per ml. solution.

It is evident that, in sulphate solutions, the ion-exchange capacity of clay for uranium is limited to a value much below that accepted for cation exchange. This phenomenon is consistent with the use of anion exchange resins for recovery of uranium from solution on an industrial scale and suggests that some of the uranium retained in ore residues may be absorbed by anion exchange instead of, or in addition to, cation exchange. Our current interest in the matter lies in devising simple methods for the desorption of uranium from clay-like minerals, in the light of the results reported here.

Table 1. Absorption of Uranium on Cationic Resin

gm. resin / ml solution	Distribution ratio	
	in sulphate solution	in nitrate solution
0·025	16	64
0·25	15	100

A Method for analysing Mechanical Motion

In the particular frequency-range of 10,000–50,000 cycles per second and peak-to-peak amplitudes of the order of 0·002 in. there are several methods, for example, optical, electrical, magnetic, etc., for measuring mechanical vibration. However, in this high-acceleration region of approximately $10^4 g$, certain effects which take place can lead to useful information concerning resonant vibrating members which could not be obtained by other means.

To be specific, assume a right circular cylinder of aluminium of ¼ in. diameter symmetrically driven in fundamental longitudinal resonance at 22,000 cycles per second. Under these conditions there is a loop of motion at either end of the rod, the amplitude being 180° out of phase at one end from that at the other end. There is a node of motion at the centre of the bar. Placing one's fingers lightly along the resonating bar no definite sensation is experienced until a broad threshold of the order of 0·0005–0·001 in. amplitude (peak to peak) is attained at the loops of motion. At 0·001 in. a very definite force acts on the fingers, pushing them toward the node from both loops. It appears as if the static friction between the fingers and the surface of the bar has been reduced considerably since the experience is that of a very smooth feeling. Conversely one experiences resistance, though not of the static friction variety, as the fingers are pushed from node to loop. At the loops of motion the reduced friction effect is greatest, whereas at the node the static friction one observes below 0·0005 in. is in effect.

In order to investigate this phenomenon thoroughly a more quantitative criterion than touch sensation was necessary. Since the surfaces of the metallic cylinder are circular and relatively smooth, a viscous substance, which however has some mass, was required, and a jewellers' abrasive lapping paste mixed with water was used. To specify completely the forces and amplitudes in a vibrating bar one must know the radial amplitude U, which by simple theory is related to the longitudinal amplitude $W = A \cos kx$ by the expression $U = r\sigma W$ [1] (where r is the radius of the bar, σ is Poisson's ratio, and $k = \omega/c = 2\pi/\lambda$). For bars the radii of which are small compared to wavelength, as in the case here, these equations for all practical purposes are borne out by more rigorous theory[1].

The ratio of the maximum radial amplitude to the maximum longitudinal amplitude in a straight bar is $\frac{U}{W} = \frac{r\sigma\omega}{c}$ and for the aluminium bar at hand amounts to 0·207 r. For the same amplitude at the loop the only way to increase the radial amplitude is to increase the frequency or the radius.

Application of the paste in very small quantities to the surface of a bar ⅛ in. radius shows no action below 0·001 in. amplitude at the loop. At about 0·002 in. consistency of a kind is attained. Between 0·001 and 0·002 in. the action is erratic. At roughly 0·002 in. the paste motion is towards the node of vibration from either side of the node although there is a tendency for the gravitational forces to take effect on the paste and roll the paste to the bottom side of the bar, which was held in an attitude parallel to the work table. Increasing the amplitude on this bar to 0·003 in. did not cause any noticeable change in paste motion. By doubling the radius of the bar to ¼ in. the paste motion seemed to be enhanced and a definite change took place by the tripling of the radius to ⅜ in. At this radius the paste moved independent of the attitude of the vibrating element with respect to the work-table. In other words the forces causing the paste motion were higher than the gravitational forces. The velocity of the paste motion was also considerably enhanced.

Since a resonant drive system was used the frequency could not be changed while maintaining the same amplitude of vibration. With the present equipment larger diameter rods could not be driven at sufficient amplitudes to compare with the work done on the three bars, because of the loading effect, since the total kinetic energy of the bar contains two terms, one depending on the cross-section of the bar and the other on the square of the cross-section. In new equipment tests several points will be checked: the effect of frequency, larger amplitudes, temperature, paste, smoothness of surface of bar, etc. Aluminium was chosen as the vibrating member because the alternating stresses involved for 0·002 in. (about 13,700 lb./sq. in.) would be sufficient to generate considerable heat in rod the damping capacity of which is higher than aluminium, the heat affecting the surface tension.

It appears from this work that the ratio U/W above a certain threshold W is a quantity which determines the ability of a paste to respond to certain forces generated in a bar which are sufficiently great in magnitude to compete against surface tension and gravitational forces acting on the paste. At the same time the forces are such that paste tends to be driven from loops of motion and to pile up at the nodes, leading to the belief that this technique may be applied to more intricate shapes and to asymmetrical driving to give information which cannot be derived from theory as yet.

A Magneto-resistance Displacement Gauge

THE very large Hall and magneto-resistance effects in indium antimonide (InSb) have led to a number of suggested practical applications[1–3]. We report here, briefly, some details of the use of the transverse magneto-resistance effect for the detection and measurement of small displacements.

The principle of the method is that the displacement to be measured causes a small strip of indium antimonide crystal to change its position relative to a permanent magnet, the poles of which are shaped in such a way that there is a strong field gradient in the direction of movement. The mean field over th crystal and hence its resistance are then a function o position.

This simple arrangement would be liable to a larg temperature error, to overcome which it is preferabl to use two crystals rigidly connected together and so disposed that as the field in one increases that in th other decreases. This is shown schematically i Fig. 1. The two crystals form two arms of a Wheatstone bridge, the remaining arms of which consist o equivalent resistances. By adjusting one of these th bridge is balanced in the position of zero displacement

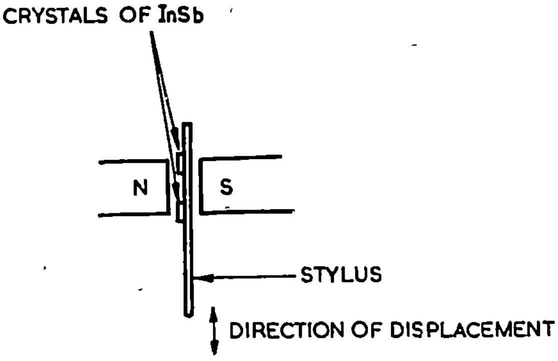

Fig. 1. Schematic arrangement of the specimens relative to the magnetic field

With such an arrangement, fed from a 2-volt cel and using crystals of size $2 \times 2 \times 0{\cdot}25$ mm., we hav been able to obtain a deflexion of 5 mm. directly o a galvanometer (⅛ m.amp. full scale, 6 ohm resistance for 1μ movement of the stylus, that is, a magnification of 5,000 times. The short-term zero stability i better than 0·25μ.

If the bridge is fed with a.c. it is possible to ampli the signal, with a considerable increase in sensitivit the limit to which is set by perfection in the mechan cal mounting and residual temperature effects, rathe than by intrinsic response. It is believed that a increase of 10–100 times should be attainable in th way.

The gauge in its direct form is particularly simp where remote reading, or recording, of results required. For example, it could be used for the co tinuous monitoring of foil thickness. The sensitivit can be quickly altered by switching the feed curren or by inserting shunts across the meter.

Acknowledgment is made to the Admiralty f permission to publish this communication.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, November 26

Institute of Neurology (in the Lecture Theatre, The National Hospital, Queen Square, London, W.C. 1), at 5 p.m.—Prof. S. T. Bok Amsterdam). "The Structure of the Cerebral Cortex as Studied y Quantitative Methods—1".* (Further lecture on November 30.)

Royal Geographical Society (at 1 Kensington Gore, London, .W.7), at 5 p.m.—Mr. B. W. Sparks: "Evolution of the Relief of the Cam Valley".

British Society for the History of Science (in the Lecture Theatre of the Science Museum, Exhibition Road, South Kensington, London, S.W.7), at 5.30 p.m.—Mr. John Fisher: "Electricity in Germany in the Eighteenth Century".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p m.—Dr. L. E. C. Hughes: First of Three Cantor Lectures on "Engineering Electronics". (Further lectures on December 3 nd 10.)

Tuesday, November 27

University of London (at Bedford College, Regent's Park, London, N.W.1), at 5.15 p.m.—Prof. Harold Richardson: "The Growth of Physical Ideas"* (Inaugural Lecture).

Cement and Concrete Association (at the Institution of Civil ngineers, Great George Street, London, S.W.1). at 5.30 p.m.—Dr. . B. Morice: "The Analysis of Prestressed Concrete Structural Members and the Application of Recent Research".

Institute of Marine Engineers (at 85–88 The Minories, London, .C.3), at 5.30 p.m.—Mr. C. D. Boadle: "Some Safety Considerations of Nuclear Power Reactors".

Research Defence Society (in the Physiology Lecture Theatre, niversity College, Gower Street, London, W.C.1), at 5.30 p.m.—rof. A. A. Miles: "Resistance to Infection—The Experimental pproach". (Twenty-fifth Stephen Paget Memorial Lecture"); followed by the Annual General Meeting.

Royal Institute of Chemistry (joint meeting with the Sir John ass College Chemical Society, at the Sir John Cass College, wry Street, London, E.C.3), at 6.30 p.m.—Prof. R. S. Nyholm: Magnetism and Inorganic Molecules".

Society of Instrument Technology (at Manson House, Portland Place, London, W.1), at 7 p.m.—Prof. J. D. McGee: "Television Technique applied to Observation and Control".

Wednesday, November 28

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Prof. R. H. S. Thompson: "The Biochemistry of Nervous Diseases".*

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m —Mr. J. S. Hales: "Air Conditioning of Buildings" Alfred Bossom Lecture).

Institute of Fuel (at the Institution of Civil Engineers, Great eorge Street, London, S.W.1). at 5.30 p m.—Dr. R. S. Scorer: "The Cost in Britain of Air Pollution from Different Types of Source".*

University of London (at King's College, Strand, London, W.C.2), 5.30 p.m.—Dr. A. B. Wardrop: "Structural Aspects of Surface rowth in Plant Cells".*

British Institution of Radio Engineers (at the London School Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Dr. G. N. Patchett: "Colour Telesion".

Society for Analytical Chemistry, Physical Methods Group t the Chemical Society, Burlington House, Piccadilly, London, W.1), 6.30 p.m.—Twelfth Annual General Meeting.

Institution of Mechanical Engineers, Automobile Division t 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—ebate on the motion that "There is no Future for Laminated Plastics Automobile Body Construction".

Society of Chemical Industry, Food Group (at 14 Belgrave quare, London, S.W.1), at 6.45 p m —Mr. G. Clewlow and Mr. W. ixon: "New Aspects of the Evaluation of Biscuit Flour"; Dr. . E. Bender: "The Stability of Vitamin C in a Commercial Fruit Squash".

Royal Institute of Chemistry (joint meeting with the South-West Essex Technical College Chemical Society, at the South-West Essex Technical College, Forest Road, Walthamstow, London, 17), at 7 p.m.—Dr. A. T. James: "Gas-Liquid Chromatography".

Thursday, November 29

University of London (in the Anatomy Theatre, University ollege, Gower Street, London, W.C.1), at 1.15 p.m,—Mr. K. M. arbour: "A New Approach to the Nile Waters Dispute".*

Physical Society, Optical Group (in the Lecture Hall of the ational Physical Laboratory, Teddington), at 2.30 p.m.—Mr. J. W. tes: "Polarimetry: Present Use and Future Aims"; Mr. E. J. llham: "A Precision Photoelectric Polarimeter and Automatic ccharimeters for Industrial Use"; Mr. R. Stanley: "The Belling-m and Stanley Photoelectric Polarimeter".

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Prof. G. F. Marrian: "Some Recent Progress in the Biochemistry of the Œstrogenic Hormones".*

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Dr. W. H. J. Vernon: "Metallic Corrosion and Conservation".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. R. O. Kapp: "Differences of Opinion about Dimensions".

Society of Chemical Industry, Plastics and Polymer Group (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 6.30 p.m.—Prof. H. F. Mark: "Recent Progress in Heterogeneous Polymerization of Olefines".

Friday November 30

Textile Institute (at 10 Blackfriars Street, Manchester 3)—Dr. F. C. Toy: "The Impact of New Ideas on an Old Craft" (Emsley Lecture).

Royal Society (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Anniversary Meeting.

Physical Society (in the Lecture Theatre of the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Prof G. D. Rochester and Dr. C. C. Butler: "The Discovery of V-particles and the Properties of Hyperons".*

Institution of Mechanical Engineers, Education Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Dr. H. S. Arms: "The American System of Education and Training of Mechanical Engineers"; Prof. S. J Davies: "The Education of Engineers in European Countries".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 30 p.m.—Dr. W. G. Thompson: "Technologies in the Electrical Engineering Industry".* (Eighth of ten University Extension Lectures on "Technology and Industry". Further lectures on December 7 and 14.)

Royal Institution (at 2[illegible] Albemarle Street, London, W.1), at 9 p.m.—Dr. W. H. Glanville: "Speed on the Road and Related Effects".

Saturday, December 1

Association of Agriculture, and the British Agricultural History Society (at the Institute of Education, University of London, Malet Street, London, W.C.1), at 11 a.m.—Conference.

Mammal Society of the British Isles (at the offices of the Zoological Society of London, Regent's Park, London, N.W.1), at 2 p.m.—Symposium on "Deer".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Sir John Forsdyke: "The Origins of Coinage".*

British Interplanetary Society (in the York Hall, Caxton Hall, Caxton Street, London, S.W.1), at 6 p.m.—Mr. C. A. Cross: "The Use of Probe Rockets".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Graduate to assist in the Electron Microscopy Section of the Cavendish Laboratory on work in X-ray microscopy and related aspects of electron physics—The Secretary to the Department of Physics, Cavendish Laboratory, Free School Lane, Cambridge (December 1).

Senior Lecturer/Lecturer in Animal Nutrition or Animal Physiology in the School of Wool Technology, New South Wales University of Technology, Sydney, Australia—The Agent General for New South Wales, 56 Strand, London, W.C.2 (Australia, December 14).

Chair of Chemistry—The Secretary, The University, Exeter (December 15).

Farm Demonstrator (with a degree in agriculture, or an honours degree in pure science, followed by an adequate postgraduate qualification in agriculture, together with farming experience) at Cambridge University School of Agriculture—The Secretary, School of Agriculture, Cambridge (December 15).

Lecturer (preferably with a degree in chemical engineering, chemistry or engineering) in Chemical Engineering—The Registrar, King's College, Newcastle-upon-Tyne (December 17).

Senior Lecturer in Psychiatry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 18).

Lecturer in Agriculture (Animal Husbandry) at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 21).

Scientific Officer, Grade I (with a first-class honours degree with chemistry as a major subject) in the Defence Standards Laboratory, Department of Supply, Alexandria, New South Wales, Australia, for research into problems associated with the production of protective coatings on metals by electrochemical means and with the evaluation of such coatings for effectiveness and serviceability as corrosion barriers—The Senior Representative (AP.70), Department of Supply, Australia House, Strand, London, W.C.2 (December 22).

PROFESSOR OF GEOGRAPHY at the University of Ceylon—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Ceylon, December 28).

LECTURERS (2) IN VETERINARY PATHOLOGY, and a LECTURER IN CLINICAL VETERINARY PATHOLOGY—The Registrar, The University, Liverpool (December 29).

CHAIR OF APPLIED MATHEMATICS in the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 31).

LECTURER IN SOCIAL ANTHROPOLOGY at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 31).

PHYSICS TECHNICIAN (with a good technical background and able to undertake instrumental designs) IN THE RADIOTHERAPY DEPARTMENT, Auckland Hospital, for work which will include the construction of devices of a precision nature in addition to general duties in maintaining deep X-ray therapy units—The High Commissioner for New Zealand, New Zealand House, 415 Strand, London, W.C.2 (New Zealand, December 31).

SENIOR LECTURER IN BIOCHEMISTRY at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 31).

SENIOR LECTURER or LECTURER IN GEOLOGY at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 31).

SENIOR LECTURER or LECTURER (preferably with a special knowledge of mineralogy, economic geology, or similar subjects) IN GEOLOGY at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 31).

SENIOR TECHNICIAN IN THE FACULTY OF AGRICULTURE, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 31).

POSTDOCTORAL FELLOW (with a Ph.D. in physical chemistry, and experience either in high polymer chemistry or in reaction kinetics) IN THE DEPARTMENT OF PHYSICAL CHEMISTRY—Prof. F. S. Dainton, School of Chemistry, The University, Leeds 2 (January 1).

TURNER AND NEWALL FELLOW for research in engineering, inorganic chemistry or physics, at Durham or Newcastle—The Registrar, University Office, 46 North Bailey, Durham (January 5).

ASSISTANT or ASSOCIATE PROFESSOR (with graduate training in physics, and also research and practical experience in the field) OF GEOPHYSICS—The Head of the Department of Physics, University of British Columbia, Vancouver 8, B.C., Canada.

FIELD OFFICER (AGRICULTURE) (aged 30–40, with sound tropical experience of experimental farm management and a knowledge of preparing and recording experiments) IN THE TANGANYIKA GOVERNMENT AGRICULTURAL DEPARTMENT—The Crown Agents, 4 Millbank, London, S.W.1, quoting M.3A/43540/TA.

GEOLOGISTS (with a first- or upper division second-class honours degree in geology) IN THE MINES AND GEOLOGICAL DEPARTMENT, Government of Kenya, for geological mapping, examination of mines and prospects, and the preparation of geological maps and reports suitable for publication—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.99/7/02.

LECTURER (with a university degree in physics or electrical engineering, together with experience in telecommunications, radar, microwave techniques, or allied subjects, and preferably with a knowledge of aeronautical applications) IN THE DEPARTMENT OF AIRCRAFT ELECTRICAL ENGINEERING—The Recorder, College of Aeronautics, Cranfield, Bletchley, Bucks, quoting Ref. ER/L.

LECTURER (with an honours degree or equivalent qualification, and able to teach inorganic and analytical chemistry to Grad.R.I.C. standard) IN THE DEPARTMENT OF CHEMISTRY AND BIOLOGY, College of Technology, Liverpool—The Director of Education, 14 Sir Thomas Street, Liverpool 1.

RESEARCH OFFICER (with an honours degree in bacteriology, and preferably postgraduate experience in virology) mainly for tissue culture work—The Secretary, Research Institute (Animal Virus Diseases), Pirbright, Surrey.

SENIOR LECTURER (with a degree in engineering or in physics and experience in the refrigeration industry) IN REFRIGERATION at the National College for Heating, Ventilating, Refrigeration and Fan Engineering—The Clerk to the Governors, Borough Polytechnic, London, S.E.1

SENIOR SCIENTIFIC OFFICER (with a first- or second-class honours degree or equivalent in engineering, mathematics or physics, and at least three years postgraduate research experience) with the Ministry of Supply at Boscombe Down, near Amesbury, Wilts, for helicopter research—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.293/6A.

PERGAMON PRESS

LONDON & NEW YORK

A SELECTION OF NEW AND RECENTLY PUBLISHED BOOKS

Hypotensive Drugs

Edited by M. Harington. The proceedings of a symposium on hypotensive drugs and the control of vascular tone in hypertension held in London in April 1956 at the Wellcome Foundation. An authoritative statement of this medical problem, and the advances in the discovery of drugs with real clinical value in the control of hypertension.

Approx. 228 pp. 50/- net ($8.00)

Science and Human Life

By J. A. V. Butler. An examination of the advances of scientific knowledge and the relating influence it has on human conduct. This book also gives a fresh treatment to the controversy so often thought about and discussed —whether the principles or laws that govern human society are similar to those laws which govern the physical world.

75 pp. 35/- net

Vistas in Astronomy, Volume II

Edited by Arthur Beer. This book is the second of two which comprise a complete survey of astronomy and its allied sciences. Very broad in scope, this book is also valuable to those whose interest lies in adjacent fields, such as physics, mathematics and geophysics.

Approx. 980 pp. Illustrated £15/15/- net ($44.00)

The Second International Seaweed Symposium

Edited by Trygve Braarud and N. A. Sorensen. An important and well co-ordinated study by scientists and representatives f the seaweed industry which promotes scientifically the explorations of seaweed resources and clarifies problems rising in the application of available knowledge and experimental results.

40 pp. Illustrated 60/- net ($9.00)

The Airglow and the Aurorae

Edited by A. Dalgarno and E. B. Armstrong. Published as a special supplement to "Journal of Atmospheric and Terrestrial Physics." Papers include the latest observational and theoretical work on these subjects. Even the non-expert will find these papers easily readable. A few of the papers are of a review character, but the majority are original contributions which have not appeared elsewhere in the literature.

429 pp. Illustrated £7/10/- ($22.50)

Solar Eclipses and the Ionosphere

Edited by N. J. G. Beynon and G. M. Brown. This volume consists of a collection of 50 papers presented at a symposium held in London, August 1955. People interested in understanding and interpreting geophysical appearances will find these observations made during solar eclipses and their influence on ionospheric phenomena of great value.

339 pp. Illustrated £7 net ($21.00)

Atomic Structure and the Strength of Metals

By Professor N. M. Mott, Cambridge. A series of lectures designed for the university students of the humanities to encourage interest and clearer understanding of particular fields of scientific research. It explains in non-scientific terms the properties of atoms and their relationship with the properties of metals.

64 pp. Illustrated 15/- net ($2.75)

Progress in Nuclear Physics, Vol. 5

A valuable work of reference in nuclear physics where both technical and theoretical advances are represented, and are treated at a level which is unquestionably valuable to the scientist as well as bringing to the informed reader a clear understanding of the subject.

328 pp. Illustrated Approx. 70/- net

LECTURES AND COURSES

UNIVERSITY OF LONDON

A course of two lectures on "Nuclear Magnetic Resonance Spectroscopy and Applications to Organic Chemistry" will be given by Professor J. D. Roberts (California) at 5.30 p m on December 3 and 5 at Queen Mary College, Mile End Road, E 1.

Admission free, without ticket.

JAMES HENDERSON,
Academic Registrar.

UNIVERSITY OF LONDON

A lecture on "Structural Aspects of Surface Growth in Plant Cells" will be given by Dr. A. B. Wardrop (Division of Forest Products, C S.I.R.O.) at 5.30 p m, on November 28, at King's College, Strand, W.C.2.

Admission free, without ticket.

JAMES HENDERSON,
Academic Registrar

NORTHERN POLYTECHNIC

DEPARTMENT OF PHYSICS

SHORT LECTURE COURSES

TRANSISTOR CIRCUITS

Part I. Tuesdays at 7.15 p.m Four lectures beginning January 15, 1957.

Part II Tuesdays at 7.15 p.m. Six lectures beginning February 12, 1957.

RADIO-FREQUENCY NOISE TECHNIQUES

Mondays at 7.15 p.m Six lectures beginning February 25, 1957.

TECHNOLOGY OF COLD CATHODE VALVES

Thursdays at 7.15 p.m Six lectures beginning February 28, 1957.

Inquiries should be addressed to the Head of Department of Physics, Northern Polytechnic, Holloway, N.7. (Telephone NORth 1686).

OFFICIAL APPOINTMENTS

NEW ZEALAND DEPARTMENT OF AGRICULTURE

Vacancy No. 1715. Biochemist, Wallaceville Animal Research Station. Salary up to £1,250, as merited This is the ultimate maximum for an average officer but an outstanding officer may advance to £1,500 per annum. Qualifications desired. B.Sc. Duties: The study of trace elements and their relation to disease in farm animals. Generous travelling allowance for successful candidate and his family.

Application forms and conditions of appointment may be obtained on request from: High Commissioner for New Zealand, 415 Strand, London, W.C.2, mentioning this paper and quoting reference number A3/4/59. Completed applications to be lodged in London not later than November 30, 1956

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Lecturer in Engineering (Mechanical). Preference will be given to candidates with a major interest in heat transfer. A knowledge of some aspect of nuclear engineering would be an advantage. University regulations permit teaching staff to read for the degree of M.Sc. and Ph.D. Applications will also be considered from engineers who would be interested in a temporary appointment of two or more years. Salary scale: £650 to £1,350 per annum. Membership of F.S.S.U. and children's allowance scheme. Initial salary according to qualifications and experience.

Applications should be sent not later than December 3, 1956, to the Registrar, The University, Manchester, 13, from whom further particulars and forms of application may be obtained. Applications by airmail (no forms) will be considered from overseas candidates

LONDON COUNTY COUNCIL INVITES applications for appointment in Scientific Branch of Public Health Department as Laboratory Assistant for duty at Central Laboratory. Inclusive weekly rate 167s 6d rising by annual increments to 215s. Post pensionable.—Details and application forms from Medical Officer of Health (PH/D. 1/2226), County Hall, S.E.1, last date December 14.

NOTTINGHAM NO. 1 HOSPITAL MANAGEMENT COMMITTEE

Applications are invited for a post as Assistant Physicist (Basic Grade) in the Physics Department of the Hogarth Radiotherapeutic Centre at the General Hospital, Nottingham. Candidates should have a good honours degree in physics. Experience in hospital physics is not essential, but experience in electronics would be an advantage. Work in the Centre includes radioactive isotopes, deep, superficial, and rotation therapy and radium and radon treatment. Salary according to Whitley Council scales For first- and second-class honours £525 by £25 to £625 (others £475 by £25 to £575) for probationary period. Subsequent salary in basic grade £650 by £30 to £740 by £35 to £845 Starting salary will depend on post-graduate experience.

Applications, with names of two referees, to be sent to the undersigned, from whom further particulars may be obtained.

HENRY M. STANLEY,
Group Secretary.

LONDON COUNTY COUNCIL

Paddington Technical College, Assistant, Grade B, mainly for C and G intermediate and final science laboratory technician's courses Must be able to offer at least two of the following subjects, chemistry, physics, biology, calculations, drawing, workshop practice, and have had good laboratory experience (industrial or educational). Burnham F.E. salary scale £650 by £25 to £1,025 plus London allowance and additions for qualifications, training and experience.

Application forms from Secretary at College, Saltram Crescent, W.9, returnable December 14, 1956. (2222).

COLLEGE OF AERONAUTICS

Applications are invited for the appointment of Demonstrator in the Department of Aircraft Electrical Engineering to take charge of the everyday running and maintenance of a teaching and research laboratory devoted to work in the telecommunications, radio navigational, radar and microwave fields Preference will be given to candidates holding a university degree or professional qualification. Experience in aeronautical applications of any of the above fields is an added qualification but candidates without such experience will be considered. Salary dependent on qualifications and experience within a range rising to £1,050 per annum with family allowance. Successful candidate would be considered for promotion to a lectureship appointment at a later date.

Applications (quoting reference ER/D), giving full particulars and the names of three referees, should be forwarded to the Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks, from whom further particulars may be obtained.

CENTRAL ELECTRICITY AUTHORITY RESEARCH LABORATORIES, LEATHERHEAD, Surrey, require ENGINEERS in the Generation Section. Investigations cover a wide range of problems associated with conventional and nuclear power stations, including electrostatic precipitation, cooling towers, and heat transfer in the nuclear fuel elements and heat exchangers. Experience desirable but not essential. Ability to apply fundamental knowledge to a wide range of problems important. Candidates for Second and Third Assistant Engineer vacancies should preferably have honours degree with previous research experience. For others a pass degree or H.N.C. is acceptable.

Second Assistant Engineer, £995 to £1,345
Third Assistant Engineer, £930 to £1,140
Fourth Assistant Engineer, £735 to £910
General Assistant Engineer, £520 to £695

according to qualifications and experience

Applications, stating age, qualifications, experience, present position and salary, to D. Moffat, Director of Establishments, Winsley Street, W.1, by December 12, 1956. Quote Ref. N/927.

EXPERIMENTAL OFFICER REQUIRED BY the Atomic Weapons Research Establishment, Aldermaston, Berks, to be responsible for a small team engaged on general chemical analysis and the analysis of rare metals Applicants should be at least 26 years of age and possess higher school certificate (science), Inter.B Sc. or equivalent, but possession of H.N.C. (chemistry) or a general degree would be an advantage Experience in the handling of radioactive materials is desirable. Salary: £940 to £1,155 per annum (male). Contributory superannuation scheme. A house or assistance towards legal expenses on house purchase will be available for married officers living beyond daily travelling distance.—Requests for application forms by postcard to the Senior Recruitment Officer at the above address. Please quote Ref. 1324/34.

LOCAL APPOINTMENTS COMMISSION

DUBLIN

POSITION VACANT:—BIOCHEMIST
ST. KEVIN'S HOSPITAL, DUBLIN

Essential qualifications include (i) at least th
years' experience in the procedures of
chemistry or chemical pathology, (ii) a higher
gree in biochemistry or physiological chemi
such as the M.Sc., Ph.D., or equivalent. Sal
scale: £1,182 to £1,608. Upper age limit:
years, with extensions in certain cases.

Application forms and particulars from the S
retary, Local Appointments Commission, 45 Up
O'Connell Street, Dublin. Latest time for
ceiving completed application forms: 5 p.m.
December 7, 1956.

ATOMIC ENERGY RESEARCH ESTABLISHMENT

HARWELL

requires a

HISTOLOGIST/PATHOLOGIST

at the

WANTAGE RADIATION LABORATORY

Duties will include microscopical examination of the tissues of animals, which have been maintained on artificial diets containing a proportion of irradiated foodstuff

Applicants should possess a first- or
second-class honours degree and have a
knowledge of the normal histological pictur
of rat tissues

Salary The post will be graded as
Senior Scientific Officer, £1,155 to £1,35
per annum; or Scientific Officer, £615 t
£1,065 per annum, according to age, experience and qualifications.

Send postcard for further details and application form, which must be returned by
December 4, to Establishment Officer
A.E.R.E., Harwell, Didcot, Berks, quoting
reference 676/34.

Applications (six copies), giving age, quali
tions, experience and the names of three refe
should be sent to the Secretary, Advisory C
mittee on Colonial Colleges, 1 Woburn Sq
London, W.C 1. Closing date December
1956.

CRUMPSALL HOSPITAL

MANCHESTER, 8

HOSPITAL BIOCHEMIST

Applications are invited for the post of As
ant Biochemist (basic grade) in the Group Lab
tory, Crumpsall Hospital, Manchester, 8. Ap
cants should hold a B.Sc. in chemistry or
chemistry, or the A.R.I.C. This post offers
cellent training facilities in a wide field of
pital laboratory biochemical techniques. S
range £475 to £845 according to experience
qualifications.

Applications should be sent as soon as pos
to the Hospital Administrator, Crumpsall Hos
Manchester, 8.

INTRODUCTION TO

SOLID STATE PHYSICS

by

Charles Kittel

(Professor of Physics, University of California)

SECOND EDITION

Size: 9¼ in. by 6 in. *617 pages* *Illustrated* *96s. net*

One of the objects of this work is to emphasise those areas of active research in solids which may be discussed in terms of simple physical models. The second edition includes fuller explanations of the basic concepts than did its predecessor, particularly in the areas of crystal symmetry and energy band theory.

STERIC EFFECTS IN ORGANIC CHEMISTRY

Edited by

Melvin S. Newman

WITH TWELVE CONTRIBUTORS

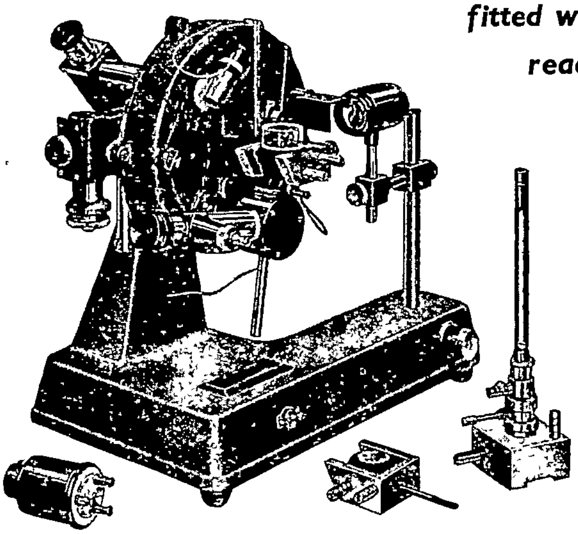
Size: 9¼ in. by 6 in. *710 pages* *Illustrated* *100s. net*

This book provides enough data to enable the reader to interpret for himself reactions and phenomena involving a wide range of steric effects. Laboratory workers and theoretical chemists will find in it the first thorough discussion of an area of growing importance in modern organic chemistry.

37 ESSEX STREET, LONDON, W.C.2

PRECISION BS INSTRUMENTS

Pulfrich Refractometer



fitted with circle divided on glass and giving readings on opposite sides of the circle to 5 seconds, by double microscope

This instrument possesses many advantages ov the older type of Pulfrich refractometer and is us in all parts of the world for testing oils, opti glass, chemicals, drugs, etc.

We shall be pleased to demonstrate this instrument and give any advice as to its use, by appointment at our Works.

COST AND PRICE OF *NATURE*

T has been decided that at the beginning of 1957 the price of *Nature* is to be raised from 2*s*. to 2*s*. 6*d*. -an increase of 25 per cent. The decision was taken ith reluctance, and not without considerable eliberation. Certain obvious economic factors have ontributed towards enforcing this step. For example, credible though it may seem, the great increases in aper and printing charges, especially over the past n years, and more especially during the past two three years, have now brought us to the stage when e cost of producing a copy of *Nature* is higher than e price charged. It therefore follows that, with ich a journal as this which has no outside financial ipport or subsidies, those who use it as an advering medium are its strongest supporters financially, at is, apart from the publishers who, throughout e years, have done everything they can to encoure its growth and development. It is not irrelevant point out that though in 1957 *Nature* will cost 0 per cent more to the buyer than it did in 1939, e rates charged to the advertisers have been raised uch more than that mainly owing, of course, to creased costs of production.

There are few scientists to-day who know that at inception and for about the thirty ensuing ars *Nature* was published at a financial loss—a s which was sustained entirely by the publishers io then, as now, willingly undertook certainculiar responsibilities for the advancement of ence.

Other journals, both scientific and otherwise, and newspapers have, since the beginning of the cond World War, found it necessary to increase eir prices (in some cases quite drastically). A large mber, even during the past two years, have raised eir subscriptions from 10 to as much as 50 per it. In many cases (and this applies especially to wspapers, due mainly to paper rationing) the rise price has been gradually accompanied by a luction in the number of pages and consequent ount of text. This has not been the case with *ture* ; in fact, the reverse is true for the amount of t in an issue of *Nature* to-day is well-nigh double it of an issue of 1939 and even more than that of l earlier issues.

In this connexion, Table 1 is of interest. There set out the total number of pages of text matter pearing in twenty-six issues (equivalent to one ume extending over a period of six months) of the irs 1939, 1947, 1955 and 1956. These years are of vious significance. It will be noted that the actual mber of pages in 1947 are less than the corrending six months in 1939 ; yet the amount of t in 1947 was much more, for by then there had n an accumulation of war-time economies, such smaller type, more economic (though essentially attractive) lay-out, and so forth. These economic asures still hold ; therefore, to the figure 1,446 (for 1956) about another 400 pages could justifiably be added for comparison with the figure for 1939. This indicates that in 1956 almost twice as much text is offered per volume as compared with 1939. (We are glad to announce that one war-time economy is to be jettisoned in 1957 in that we shall be returning to the wider page margin though the type-area will remain the same. This will not only add dignity to the journal but also offer a utilitarian advantage to the inveterate note-maker.)

Table 1

Period (June-Nov. ; 6 months)	No. of letters and special articles	No. of columns of letters and special articles	Total No. of pages
1939	313	484	1,086
1947	497	644	904
1955	627	1,071	1,194
1956	833	1,323	1,446

Also in Table 1 are indicated the number of actual letters and special articles and the number of columns devoted to these for the same periods covered. The term 'special articles' here applies to those contributions which are really extended research communications in contradistinction to the general articles, reports of scientific meetings, etc., which are not included in Table 1. These special articles are invariably inserted just before the letters (one to four articles per issue).

The distribution of *Nature* is not without interest in this connexion, though it cannot be too strongly emphasized that circulation figures of a journal such as *Nature* are meaningless, at any rate, to the many readers who bear no financial responsibility in connexion with the journal. So widely known and read is *Nature* throughout the world that it is understandable when a person suggests that its *numerical* circulation must be enormous. But this is not the case. The head of one of our leading scientific institutes once said that he and his colleagues had estimated the numerical circulation from various data which he did not at the time disclose. We wish their estimate had been right ; but they were 800 per cent out in their calculations. At any rate, the estimate did indicate how much *Nature* is used, if not purchased.

Bound up with distribution is contribution, and Table 2 shows those countries from which letters and

special articles were published during the immediate past *six months* (a period corresponding to the 1956 period in Table 1)

The countries in Table 2 are arranged in order of number of communications published from them over the six-month period: for example, United States, 162; Canada, 35; Japan, 17; Czechoslovakia, 12; Hungary, 7; Germany, 7; Israel, 5; Denmark, 4; Egypt, 4; Kenya, 3; U.S.S.R., 1. The complete figures are not given, for they would be misleading, because only a short period is covered. Had this period been extended to, say, one year, more countries would have appeared in the list. In fact, over a longer period it would be seen that most countries throughout the world where scientific research is being carried out use *Nature* for recording and discussing their results.

If time and space allowed comparisons of this (1956) period with similar periods during selected years over the past twenty years, other items of interest would emerge. Table 2 alone, for example, if compared with certain previous years, would stress the great scientific advancement which has taken place in Colonial areas during the post-war years due mainly to government and otherwise sponsored research, and also the commendable efforts being made by the newly established Colonial university and other scientific centres. Moreover, there is an indication that the U.S.S.R. is returning to the fold where she used to play a prominent part before sinking into a period of silence behind the Iron Curtain.

At present, however, we are concerned with Table 2 only so far as it is an indicator of the *geographical* distribution of contributors to *Nature*. This distribution is entirely world-wide, and the same applies to the readers and subscribers, though certainly not numerically; for, by and large, there must be very few working scientists in the world who are unable conveniently to read or refer to any copy of *Nature* they require, no matter whether they be subscribers or not. But geographical distribution is not the same as numerical distribution, in that probably *Nature* is more widely distributed geographically than even some metropolitan daily newspapers. For every issue of *Nature* published there are many more readers. It is fair to emphasize this especially since the advertisers, whose rates have been increased much more than the published price, are in a practical way much stronger supporters of the journal than its readers. There are many and various reasons for this. For example, up to as recently as three years ago, more than two hundred copies of each week's issue of *Nature* were subscribed for from within the U.S.S.R. Then this number was suddenly reduced to about a dozen; yet scientists who have recently visited that country can tell us that they saw photocopies of *Nature* at every scientific centre they visited. Elsewhere, especially in Britain and the United States, it is common to hear quite an active and even outstanding scientific worker state, or maybe even complain, that he is unable to get hold of a copy of *Nature* for ten days to three weeks after it has been published because his colleagues must have their turn first with the one issue for which they subscribe. Comparisons are sometimes misleading, sometimes even odious; but the fact cannot be refuted that at present an issue of *Nature* costs, in Britain, about half the price of a packet of twenty cigarettes and much less than most readers would expect to pay for one seat for one performance at a theatre.

There are, of course, especially among the younger scientists, many who cannot be expected to subscribe personally to a general journal such as *Nature* particularly those who must, or prefer to, subscribe to other journals. But *all* contributors, whether they be also subscribers or not, and especially authors o special articles and letters, can do much more than they are doing towards keeping the costs of production down. For example, there is still too much rushing into print, and this does not apply solely to the younger enthusiasts. It is sometimes even followed by a request to cancel a contribution which has most probably already cost several pounds sterling in setting of type and maybe even making of blocks for illustrations. Other contributors all too readily make corrections in their proofs—and such corrections are nowadays very expensive to make For example, it costs about 1*s*. 6*d*. to insert on comma in a proof.

The average weekly authors' corrections, includin cancelled matter owing to articles being withdrawn or revised copies submitted after type has been set up amount to seven columns, or in other words th equivalent of two complete weekly issues is wasted eac half-yearly volume (26 *numbers*). *The entire cost o this is borne by the publishers; the time waste by editors, compositors and readers needs n emphasis.*

In many cases, more care at the initial stages o preparing a manuscript would obviate such expensiv corrections. Moreover, corrections are often made in a wasteful and sometimes futile attempt to improv style. The costs of blocks for illustrations also hav soared, yet on occasions we are asked to discard block in favour of a new one. As one editor of *Natu* pointed out in a lecture before the Royal Society o Edinburgh, it would perhaps be a good idea if ever contributor to *Nature* asked himself the three fo lowing questions before submitting his contribution (1) Have I said exactly what I want to say? (2) Have I said it in the minimum number of words? (3) Is worth saying at all? It should here be emphasize that no charge is ever made to authors for correction or cancellations.

The demand for space in the "Letters to th Editors" section is continually on the increase By and large, of course, this is a very welcom trend; but contributors are asked to keep their communications down to the absolute minimum length.

All this is a matter of economics. *Nature* ha geographically and personally, an almost 100 p cent distribution throughout the scientific world, subscribers are being asked to contribute no mor than their fair share of the costs. This share is comparatively, indeed surprisingly, low.

CHINESE THOUGHT AND SCIENCE

cience and Civilization in China

By Dr. Joseph Needham. With the research assistance of Dr. Wang Ling. Vol. 2: History of Scientific Thought. Pp. xxiv+696+plates 14–20. (Cambridge: At the University Press, 1956.) 80*s.* net.

DR. JOSEPH NEEDHAM devotes this second volume of his monumental work to a survey of hinese thought with an eye to its relevance to cience. According to the author, the philosophy of rganism together with the Hegelian dialectic is more onsonant with modern science than the non-organic hilosophy of the past. (Whether this is so or not is question we cannot enter into here.) Further, such view of the universe can dispense with the notion f a creator by positing a spontaneous inner drive in ll things enabling them to develop with a Leibnizian pre-established harmony'. Dr. Needham's main hesis in this volume is that Chinese thought, with he exception of certain schools, was of this organic ype. From this he concludes that the outlook of ne Chinese was scientific, and, in some sense, nore scientific than that of their European conemporaries.

It is not clear why this should be so. Philosophic-ly, there is a good deal to be said for the thesis that view of the universe is a purely metaphysical natter and has no relevance for science. Even if we ere to eschew this extreme position, the most we an say is that a metaphysical view may have some ractical bearing on science. For example, given the ecessary conditions for the development of twentieth entury science, a metaphysical view—in this case he philosophy of organism—which is consonant with may, through suggesting a new point of view, help bring about this development. On the other hand, is same metaphysical view, coming at a different ncture, might inhibit the original emergence of ience. For, in order to arrive at a scientific explanaon of any natural phenomenon, it is essential, at east in the early stages of science, to be able to treat chain of events as isolable. But on the holistic ew of Nature, this is impossible, as everything is ganically bound up with everything else, and, in der to explain a particular bit of Nature, we would ave to concern ourselves with Nature in its totality. r. Needham seems, at times, not unaware of this. is, therefore, puzzling that he should think that e Chinese world view which did not lead to the nergence of science was more scientific than the ntemporaneous European view which did give rise science. Can it be that when Dr. Needham says at a metaphysical view is scientific, what he really eans is that it is true ? And this, because twentieth ntury science not only necessarily implies the ilosophy of organism but also constitutes the st word in human knowledge ? If that were e case, the Chinese should indeed be given credit r arriving independently and without the aid of odern science at a 'true' metaphysical view of the iverse.

When one takes a closer look at Dr. Needham's erpretation of Chinese thought, one finds a good al which leaves room for disagreement.

In his treatment of the early Taoist philosophers, ich is one of the least satisfactory parts of the ok, he tries to show that they took a scientific erest in Nature. Admitting that they did take a certain interest in Nature, need it necessarily be scientific ? Wordsworth, for example, was not necessarily a scientist because he took an interest in Nature. The interest the Taoist philosophers took in Nature was not scientific but philosophical, or, to be more precise, ethical. They were interested, that is to say, only in the lesson implicit in the Way (*tao*) of Nature for man as to how he should lead his life. Here, as elsewhere, Dr. Needham has not sufficiently stressed the central part played by ethics in all Chinese thought.

Again, Dr. Needham produces little evidence for his re-interpretation of the Taoist advocacy of the abolition of knowledge as confined to Confucian scholastic knowledge. There are no good grounds for departing from the generally accepted view that when the Taoist philosophers advised the rulers to "empty the minds of the people and fill their bellies" they meant exactly what they said.

In the section under discussion, one often gets the impression that the evidence Dr. Needham adduces does not quite support his conclusion—an impression that is to return again and again throughout the book.

In the section on "Fundamental Ideas of Chinese Science", one is surprised that although Dr. Needham dismisses the system of the Book of Changes as detrimental to science, he takes a much more favourable view of the Five Elements theory. This is due, perhaps, to his failure to see the full significance of the underlying similarity between the two theories: both exemplify what he calls "correlative thinking". Under each element, as under each *kua* (diagram) of the Book of Changes, is grouped a large number of things. The explanation of any given thing depends on which element it comes under. What makes this kind of explanation so different from the scientific is this: in any situation that requires explanation, there are bound to be a number of factors which most likely come under different elements, and the choice of the significant factor, and with it the element under which it comes, is arbitrary. Thus this system of explanation can never be shown to be unsound, for, whenever an explanation turns out to be false, one can always say that this is because the wrong factor was chosen as significant. Correlative thinking must have constituted one of the major obstacles to the emergence of science, as it was an ingredient to be found in a good deal of Chinese thought.

The section on Neo-Confucianism is probably the most important, as well as the most successful, part of the book. But even here one feels that Dr. Needham has overlooked certain aspects. Neo-Confucianism was both eclectic and 'scriptural'. It accepted as canonical the Confucian Classics—a haphazard collection of works differing widely in origin and point of view. Thus a multiplicity of 'scriptural' sayings, each of which can be used uncritically as authority, have to be accommodated in an uneasy system of thought. Further, according to Dr. Needham, in the Neo-Confucian system morals emerge only when organisms of a sufficiently complex nature appear on the scene. One would have thought that the starting point of the Neo-Confucians was the moral order of human society, and this they took as a pattern for the explanation of the universe. *Li* are principles which are moral as well as natural. If the Neo-Confucian philosophy is to be interpreted as a philosophy of organism, it is misleading to think exclusively of natural organisms. In fact, the Neo-

Confucian vision of the universe was constructed on a moral basis.

In a work of this length, with so many quotations from Chinese works, it is to be expected that one often feels unable to accept the author's translations. But one cannot pass without comment the section on Mohist logic. Dr. Needham has not given sufficient warning to the reader that, in the majority of cases, the text has been so radically and so extensively emended that the translation is of an exceedingly tentative nature. There are, for example, no good grounds for thinking that proposition Cs 14 (p. 179) is concerned with whether evidence is independent of morals, or that Cs 51 (p. 180) approximates to Hegelian dialectical logic.

Incidentally, there are fairly frequent mistakes in the Romanized readings of Chinese characters.

Although I have dwelt mainly on parts of the book which are more open to criticism, I should like to make it quite clear that this is the most significant work in English that has appeared in this field for many a long year. In fact, it is because the book is so full of stimulating ideas that it inevitably provokes disagreement.

THE PHYSICS OF MODERN RADIOLOGY

Radiology Physics

An Introductory Course for Radiologists, Radiographers and Medical Students. By Prof. John Kellock Robertson. Third edition. Pp. xvi+329. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1956.) 36*s*. net.

IONIZING radiations, in the form of X-rays and nuclear radiations, have been used in medicine for some sixty years, and lately the scope and intensity of their application have been immensely increased. In this time, however, comparatively few text-books have been available which both present to the student the basic radiation physics and show how it is applied to radiological practice. Among them is Prof. J. K. Robertson's "Radiology Physics", first published in 1940 and now in its third edition. The author has extensively revised the earlier editions and has added much new material. The result is an up-to-date book written to the standard required for an introductory course for radiologists, radiographers and medical students.

The first six chapters cover the subjects of alternating currents, production of high voltage, cathode rays, positive rays and isotopes, Roentgen tubes, rectification and diode and triode valves, discussing broadly the physical phenomena leading to, and underlying, the production of X-rays. The next five chapters describe the physical properties of X-rays and their measurement, including the dosimetry of X-rays in radiotherapy and including also a new chapter on the physical principles of X-ray diagnosis. Of the remaining five chapters, one is devoted to natural radioactivity, one to super-voltage tubes and particle accelerators, two to the transmutation of matter and artificial radioactivity, and the last, a new chapter, to uranium fission and nuclear reactors. Radiation protection is dealt with somewhat briefly in an appendix.

Most of the chapters have been revised and contain new material. The substance of two chapters in the earlier editions has been omitted. There i now no chapter on infra-red, visible and ultra-violet radiations, and the material on high-frequency currents has been reduced to two short sections a the end of Chapter 6. Although the omission of thes subjects leaves the book free from material strictl extraneous to radiological physics, I am sorry tha they have gone for, hitherto, "Radiology Physics" ha been one of the few books to which the medica student could turn for simple relevant informatio on infra-red and ultra-violet rays and on so-calle short-wave therapy. The value of the chapter o dosimetry would have been appreciably enhanced if in addition to the detailed description of a well known make of condenser dose meter, more consideration had been given to electronic methods Extension of the section on valve amplification t include an elementary explanation of the principle o negative feed-back could have led to a discussio of modern dose and dose-rate meters using stabl valve amplification.

Prof. Robertson's style is lucid and direct, an physical principles are presented clearly with th necessary mathematical expression where this i required. The many numerical examples worked ou in the text are valuable both as an aid to the student' understanding and as a constant reminder that numerical approach is imperative in the medical us of radiations which must always be regarded a potentially harmful and which possibly can be lethal

The book is well designed to give the basic understanding of radiation and nuclear physics to th student radiologist. It is perhaps more detailed an more quantitative than is required by the othe readers named specifically on the title page; but bot radiographers and medical students will find the ne edition helpful. Physicists teaching the elements radiation and nuclear physics to the increasin numbers of those who use ionizing radiations wi welcome this book as an aid to their work.

F. W. Spiers

PHYSICS FOR NON-PHYSICISTS

Descriptive College Physics

By Prof. Harvey E. White. Pp. x+485. (Princeton N.J.: D. Van Nostrand Company, Inc.; London Macmillan and Co., Ltd., 1955.) 42*s*.

The World of Atoms

An Introduction to Physical Science. By Pro J. J. G. McCue, with the assistance of Prof. Kennet W. Sherk. Pp. xiii+659. (New York: The Ronal Press Company, 1956.) 6.50 dollars.

EXPERIENCE alone can determine whether th needs of a group of non-specialists are bett satisfied by a conventional course in physics adjuste to their capacity, or by a more general approac attuned to their outlook; but one would feel tha either method, if only it can arouse and hold the interest, can achieve success. These two books, eac the work of an enthusiastic and resourceful teache seem admirably suited to the needs of the no scientist students for whom they are intended.

Prof. Harvey White, in selecting material for short physics course for arts students at the Universit of California, Los Angeles, appeals to the spectacul experiment and uses very little mathematics. Neve theless, the elementary mechanics is presente thoroughly and rigorously, and the reader is led on to the later chapters on atomic and nuclear physics with a good grounding in the conservation laws. There are excellently illustrated chapters on colour and spectra, introducing the important part played by the spectroscopist, particularly in the early days of modern physics. The book is a most valuable interpretation of the experimental side of physics, and manages in this way to make the subject attractive and intelligible to the non-mathematician.

Prof. J. J. G. McCue's book, which is written at the same level for the same type of student, takes a wide survey of the whole of physical science and lays more emphasis on the historical and human aspects. Why do we believe in the existence of atoms and sub-atomic particles, and how do their properties determine those of the materials in the world around us? These are the questions he asks and discusses in seventy-one chapters, each centred on a single topic. The book would probably be harder reading but for the author's foresight in concentrating attention on one thing at a time, pausing at intervals to recapitulate and consolidate the material of several chapters. The chemists' contribution to the history of atomic physics is fully described, as is also the impact of modern physics on theoretical chemistry. The closing chapters have the inevitable good account of nuclear physics, but without the usual dramatic emphasis; rather more space is, in fact, devoted a little earlier to organic chemistry. A catholic selection of suggestions for further reading ranges from original papers to biographies and popular lectures; readers interested in Anderson's first report of the positive electron, Fred Hoyle's views on the origin of the cosmos, or Sir J. J. Thomson's descriptions of baseball and American football, are directed with equal precision to the source. This is a well-written book which, in spite of its wealth of detail, holds the reader's attention to the end.

G. R. Noakes

ANTIBIOTICS IN AGRICULTURE

Proceedings First Conference on the Use of Antibiotics in Agriculture

Pp. xx+278. Publication 397, National Academy of Sciences, National Research Council, Washington 25, D.C., 1956. 2.50 dollars.

IT was an excellent idea of the National Research Council of the U.S. National Academy of Sciences to convene an international Conference on Antibiotics n Agriculture (held during October 19–21, 1955, in Washington, D.C.), and so provide an authoritative forum for discussing the many achievements, problems and expectations in the rapidly growing field of application of antibiotics in agriculture. The publication of the full report on the proceedings of this Conference is the culmination of an enterprise which was well worth while.

The leading experts of the United States and twelve other countries touched in their papers and discussion on every aspect of this fascinating topic. The scope f application of antibiotics is continuously widening. Their usefulness as therapeutic agents and as growth-promoting supplements to feeding-stuffs has been stablished beyond doubt, and newer developments oint ot considerable benefits which may be obtained from application in agronomy (promoting growth and combating infection in plants) and food preservation. Our knowledge and experience in these new fields are still very limited, but the potentialities appear to be enormous.

In 1954 about a quarter of the total production of antibiotics in the United States, namely, nearly half a million pounds, was used as supplements to feeds. All species of agricultural animals appear to have benefited from inclusion of antibiotics in their rations, the magnitude of the positive response depending on many factors. The latter were discussed by many of the contributors.

The mode of action of antibiotics as growth promoters was a subject of a very lively controversy, dominated by the general admission that the available scientific evidence does not allow the exponents of the many hypotheses to be too dogmatic. The exponents of the theme that antibiotics promote growth by virtue of their effect on the bacterial population of the digestive tract discussed the many biological pathways which could lead to an explanation of the phenomenon. The antibiotics could act as prophylactic agents guarding against 'sub-clinical' or obvious infections or as therapeutic agents in combating disease. They could function by modifying the nutritional requirements of the animals, or by specific effects on some of the essential nutrients. The experimental evidence with germ-free animals was by no means conclusive, and it added an impetus to some of the hypotheses which postulate that the antibacterial properties are not sufficient by themselves to elicit the growth-promoting effect. One of the hypotheses postulated a direct effect of the antibiotic upon intermediate metabolism of the host, others implicated hormonal systems, and still others the possible changes in the metabolic properties of the flora of the digestive tract. One feels rather sympathetic to the view expressed by one of the contributors: "Certainly there is not just one mechanism of action, but several".

The last section of the report deals with the public health aspects involved. In reviewing this part of the proceedings, one cannot do better than quote a paragraph from the summarizing talk of Dr. S. C. Keefer, director of the School of Medicine, Boston University. "It is important to assess the risk of sensitization or of sensitive reactions from antibiotic residues, and also to assess the significance of altering the oral or gastro-intestinal flora, and the emergence of resistant microorganisms as it is related to public health. Certainly the evidence to date would not lead one to believe that the risks outweigh the great benefits which have flowed from the use of antibiotics in animals, to improve nutrition or to prevent or treat diseases, or for that matter from their use as crop sprays in combating plant diseases or in the preservation of food. In any event, this area of antibiotic residues needs continuing study and research, and a fixed and rigid posture should not be taken without a sound basis of evidence. One must weigh the great advantages against the slight risks or the disadvantages."

The report is very well produced and no doubt will serve as a valuable reference book on this very important subject. There are a few mistakes, which could have been avoided by more careful editing, especially of the parts which report the general discussions. The reviewer cannot help feeling that a verbatim report was not the best way of dealing adequately with the discussion.

R. Braude

Gas Chromatography

By Courtenay Phillips. Pp. x+105. (London: Butterworths Scientific Publications; New York: Academic Books, Inc., 1956.) 25*s*.

INTEREST in gas chromatography has become widespread in the few years which have elapsed since the development of gas–liquid partition chromatography by James and Martin, and it is already a major undertaking to read all the papers which have been published in this field. With this book, the first monograph on gas chromatography to appear, Mr. Phillips has done a great deal to lighten the task of anyone intending to make use of gas chromatography. There is a valuable theoretical treatment of the subject, a carefully documented survey of most of the recent work in the field, and a useful list of references.

An important feature of the book is the wide range of techniques discussed. Although there is understandable emphasis on gas–liquid partition chromatography, there is also a section on gas-adsorption chromatography, and the use of gas chromatography in the determination of distribution functions is discussed. The short section in which the uses of adsorption and partition methods are compared might, with advantage, have been expanded; and the inclusion of some practical examples would have been helpful. All the diagrams are clear, and carefully chosen; it would have been very helpful to have included a diagram of the Martin gas-density balance, however, for it is difficult to follow a purely verbal description of this instrument without a picture.

The book is confidently recommended to all who are interested in the applications of gas chromatography. N. H. RAY

Kant's First Critique

An Appraisal of the Permanent Significance of Kant's Critique of Pure Reason. By H. W. Cassirer. (Muirhead Library of Philosophy.) Pp. 368. (New York: The Macmillan Company, 1954.) 30*s*. net.

THIS book is evidently a very able commentary upon one of the greatest philosophical works of all time. The sub-title is worthy of note, namely, the permanent significance which Kant's masterpiece has for posterity. In the light of his secluded existence at Königsberg and the rigour of his general outlook, it is scarcely to be expected that his successors would find nothing about which to differ. Perhaps to a scientist, the most important point is the justification which the present author finds for the logical dichotomy between the dual aspects of sense-givenness and the impact of the intellect upon what may be presented to it. Kant never thought of them as having a 'really' separate existence. This particular machinery was only introduced in order that some grasp of the nature of perceptual knowledge might follow.

Closely allied to this is the strong case made out by Kant that *a priori* thinking is a pre-requisite for 'knowledge proper'. Dr. Cassirer believes that much is to be gained by an approach of this kind to current problems, rather than by invoking a flood of empiricism. That a fair balance is maintained is illustrated by the writer's rejection of Kant's metaphysical deduction of the categories; but there is probably little need to stress the inacceptable character of his 'supersensible' *Ding-an-sich*, when the mind meets common objects of experience. F. I. G. RAWLINS

The Eighth Plague

By Denys Rhodes. Pp. vii+280. (London and New York: Longmans, Green and Co., Ltd., 1956.) 13*s*. 6*d*. net.

ALTHOUGH described by the author as "essentially a work of fiction", this book includes descriptions of locust swarms and hopper bands, of control operations against them with modern methods and, to a lesser extent, of field research, which must be based on first-hand knowledge, as they are extremely vivid and technically correct. The atmosphere in which this minor war between man and insect is waged in "an anonymous African territory" is effectively conveyed, and the personages —locust control officers, research workers and administrative officials—are very much alive and natural. An applied scientist reading the book will be interested in the attitude of practical field-workers to research workers, which is a mixture of amused contempt and carefully concealed respect. Less clearly brought out is the team-spirit during urgent operations; on such occasions, the author over-stresses individual leadership and makes the personages concerned exhibit heroics out of character. The not unusual conflict between scientists attempting to put their cherished ideas into practice and politicians and administrators who regard a particular approach to a problem mainly in the light of its immediate expediency is well presented. The book deserves attention, as it brings to the notice of a wide public, in a very readable form, a striking example of the kind of human problems arising in the application of science to the development of tropical countries.

Extrasensory Perception

Edited by G. E. W. Wolstenholme and Elaine C. P. Millar. (Ciba Foundation Symposia.) Pp. ix+240. (London: J. and A. Churchill, Ltd., 1956.) 27*s*. 6*d*. net.

THE sceptics are justified in ascribing much of the most interesting evidence in favour of telepathy and clairvoyance to chance; but this explanation cannot be applied to some of the experiments on card guessing, which have given results that would not have occurred by chance even if the whole human race had done nothing but guess cards from the dawn of history to the present day Well-known statisticians have found no flaw in the calculations and the results present a challenge to scientists. In May 1955 the Ciba Foundation collected a number of people who might be able to explain the facts or suggest the next step. Parapsychology and psychiatry, magic and mathematics zoology and the basic medical sciences were all wel represented at the discussions, which lasted three days and have now been published. The resulting book contains much interesting information, not only about extrasensory perception, but also about bird navigation and the homing of bees. Many marvellous things can be done by conjuring, and some remarkable performances have been shown to be due to the subconscious interpretation of sensory clues; bu the experts at this meeting were convinced tha there are some things which cannot be explained in such ways. The main impediment to progress in thi field is the fact that it is difficult to find percipient who can give statistically significant results, and much time is inevitably wasted on negative experiments. J. H. GADDUM

THEORETICAL CHEMISTRY OF METALS

By Prof. N. F. MOTT, F.R.S.
Cavendish Laboratory, Cambridge

THE use of electronic computers has made it possible to calculate the electronic wave functions of simple molecules with any degree of accuracy desired. The wave function may be taken as a series of Slater determinants; the one-electron functions contain adjustable parameters which can be found by minimizing the energy. With the increase in the speed of the computers, theoretical chemistry is approaching the point where it can, for example, rival experiment in the determination of the force constants of these molecules.

The study of solids and particularly of metals has not advanced so far. Given unlimited time on the electronic computer, we would not yet know how to set up the wave functions in the form of a series which would converge to the true one as the number of terms increased. There remain unsolved problems in the study of metals, quite apart from those like superconductivity which depend on interaction between the electrons and the lattice vibrations. Even when the nuclei are treated as being at rest, we do not know how to set up an exact wave function. This article is a description of some advances that have been made recently towards a solution of these problems and of some of the difficulties which remain.

Most attempts to set up a wave function for a metal start from the model of Bloch, which is similar to the method of molecular orbitals in chemistry. In this, each electron is treated as moving independently of all the others in a static field due to the nuclei and to the other electrons, the latter averaged in the sense of the Hartree – Fock method. To each wave function is ascribed a wave vector **k**. The determination of these one-electron wave functions is by no means an easy matter, both because of the complicated considerations of symmetry and the labour of setting up the self-consistent field. But there is no difficulty of principle here which cannot be solved, given time and effort, and much progress has been made. The question to be discussed in this article is where we go from there. One needs a wave function to describe the whole system and predict its properties. This wave function in terms of the Bloch model is a single Slater determinant of the one-electron wave functions already described, each with its appropriate spin. However, this is not a very adequate model for quantitative work, neglecting as it does the tendency of electrons of opposite spin to keep away from each other. In early work, particularly that of Wigner[1], a term was introduced into the wave function to describe this tendency, the so-called 'hole' around each electron where another electron would be unikely to be. More recently Bohm and Pines[2] showed how the size of this hole could be deduced from the existence of co-ordinates describing plasma vibrations in metals.

These methods contrast with that usual in theoretial chemistry and described as configurational interaction. In this one adds further Slater determinants in which some of the one-electron wave functions orrespond to excited states, the amplitude of each of these determinants to be determined by minimizing the energy, by perturbation theory or in some other way. This was tried for metals in a well-known paper by Heisenberg[3]; but it is not usually convenient, for the following reason. The concept of the Fermi surface, which follows naturally from the one-electron model, seems to correspond closely to the observed properties of metals; any introduction of excited states destroys the clarity of this concept.

The Fermi surface may be defined as follows in any of the one-electron models, either the single determinant or as modified by Bohm and Pines. Every state of an electron is defined by a wave vector **k** and so is the energy parameter in the one-electron Schrödinger equation. In setting up the Slater determinant which serves as the wave function of the whole system, one uses only the wave functions of occupied states, separated by unoccupied states in **k**-space by a sharp surface of constant energy that we call the Fermi surface. Since such a model must be inadequate in some respects, it is perhaps surprising that there is much experimental evidence that this surface corresponds to some property of the real metal and hence of an exact wave function. Perhaps the most direct are the properties of X-ray emission and absorption bands of light metals. We have to do here with transitions in which electrons in the conduction band made transitions to X-ray levels, or electrons from X-ray levels are excited to states just above the Fermi surface. Both types of spectra show sharp limits in accord with the one-electron theory. This was first shown experimentally by Skinner[4], who in one of his papers also discussed whether interaction between electrons ought to destroy this sharpness of the upper limit, and finds that it should not. His argument is illustrated by Figs. 1 and 2, in which Fig. 1 represents the Fermi distribution of electrons after an absorption process, the electron which has been ejected from an X-ray level being just above the Fermi distribution in the energy-level marked (*a*). Fig. 2 shows the state of affairs after emission of a

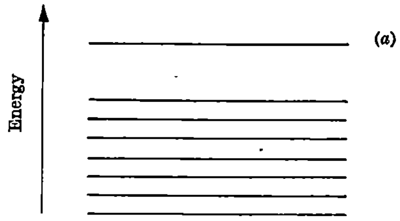

Fig. 1

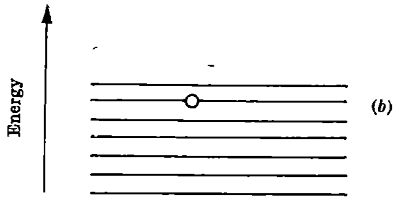

Fig. 2

quantum near the edge, there being a hole in the distribution at (*b*). Skinner shows that both these states will have a long life-time, tending to infinity as the energy interval between (*a*) or (*b*) and the Fermi limit tends to zero. This concept of a very long life-time of a slightly excited electron is confirmed by the most elementary facts about the electrical conductivity of metals; if an electron is set in motion by an electric field, it will at low temperatures in a pure crystalline metal have a very long mean free path, and hence a long life-time in its excited state. This can be terminated by interaction with other electrons, a process not without effect on the electrical resistance (Baber[5]); but the effect tends to zero with temperature and thus with the energy of excitation of the electrons above the Fermi limit.

It thus seems that the exact wave function of the electrons in a metal must have the following properties: it must allow a system of excited states, each carrying a current and with a life-time which tends to infinity as the energy of excitation tends to zero. These states will be described by a wave number **k**, and will be of two classes, as illustrated in Figs. 1 and 2. There will be a sharp dividing surface in **k**-space between the two; this is the Fermi surface.

It is thus extremely convenient to describe a metal by a single Slater determinant, improving the wave function by correlation terms or plasma vibrational co-ordinates and not explicitly introducing wave functions of the excited states which are unoccupied in the one-electron approximation. Such a description gives us a wave function with some of the properties that the exact wave function must have; for example, it retains the concept of a Fermi surface.

The importance of the Fermi surface in the theory of metals lies in the fact that electrons having energies just below it can be excited easily into the unoccupied states above it by thermal fluctuations and electromagnetic fields. Thus these electrons take part in electric, magnetic and thermal processes in metals, so that a determination of the shape of the Fermi surface is basic to any detailed understanding of most of the properties of metals and alloys. In fact, the forces within metals fall into two sharply defined groups. There are the short-range electrostatic and chemical forces, short-range because of the strong screening provided by the conduction electrons, and the effects such as that described above which depend on electrons near the Fermi distribution and can be defined only in relation to large blocks of the crystal. The effects determining crystal structure in many alloys are in the latter class (Jones[6]), though one would guess that the main part of the heat of formation of alloys is in the former.

In the Mond Laboratory in Cambridge two experimental methods are in use of which the interpretation depends on the physical existence of a Fermi surface and by which its form in **k**-space may be determined. These are the anomalous skin effect and the de Haas – van Alphen effect. The de Haas – van Alphen effect consists of the observation at low temperatures of an induced magnetic moment which varies sinusoidally when plotted against the reciprocal of the field. The moment depends on the orientation of the crystal relative to the field. The explanation of the effect in terms of the one-electron model ascribes the fluctuations obtainable with small or moderate fields to 'pockets' of electrons or positive holes, pockets in **k**-space where there is a small overlap into a new zone, or a small unoccupied space at the corner of a zone which is above the Fermi surface. The period of the fluctuations allows the shape of the Fermi surface and the number of carriers to be determined; in some cases it is as low as 10^{-5} per atom. The effective mass can also be determined and is usually low. Experiments are now in progress to study the larger main parts of the Fermi surface by using fields up to 100 kilogauss generated by discharging a bank of condensers through a coil.

That it is physically meaningful in terms of an exact wave function to say that in a given metal 10^{-5} electrons per atom overlap into a given zone is surprising and is not fully understood, though perhaps the explanation will be found along the lines indicated above, depending on the long life-time of excited states. The experiments, however, leave us in no doubt.

The existence and physical reality of pockets of electrons are very useful for the theoretical chemistry of metals. For suppose now that we try to set up the best possible wave function for a metal, starting with a single Slater determinant, using a Hartree – Fock self-consistent model and then taking account of electron correlation in some way. Such a calculation will yield energies of the one-electron states and in particular the energies at the points of particular symmetry in the zones, the corners and the centres of faces. If the de Haas – van Alphen effect shows the existence of small pockets, then these measurements will provide a very sensitive check on the energies of these points. For example, if the metal has a small number of holes and a small number of electrons, then some corner must have energy just above the central point of some face. For metals, therefore, a check on the calculations is available, of a kind not available in molecules or in insulators.

A calculation of this type has recently been carried out in the Cavendish Laboratory for the metal aluminium (Heine[7]), using a self-consistent field, and to determine wave functions by the method of orthogonalized plane waves. The magnetic properties of the metal have been investigated in the Mond Laboratory, and the calculation was undertaken with the view of explaining these properties in detail, locating in **k**-space the 'pockets' responsible for them and obtaining for the first time the detailed electronic band structure of a polyvalent metal. The work was successful in locating these pockets without any ambiguity whatever, though some slight changes in the calculated energy values were, as expected, necessary to fit the facts. The calculations and the experiments between them give a very fair pattern of the whole Fermi surface. They could be repeated for other light metals; for heavy metals the task would be harder.

Some interesting points come out of the calculations One could ask why one finds pockets containing such an extremely small number of electrons, about 10^{-5} This could happen if some zone corners had energies exceeding by a very small amount the energy at the centre of some face of another zone; but this would be an accident which should occur rarely, whereas thes small pockets seem common. The explanation i that the energies of the one-electron states, excep near zone boundaries, are quite surprisingly nea the free-electron values ($W = h^2\mathbf{k}^2/2m$). It appear that the effects of the attractive field near each nucleus and of the oscillations of a 3 *s*-wave function are of opposite sign and just balance. The wave functions themselves are very like plane waves except for these oscillations around each nucleus this has been recognized already for the alkalis. As

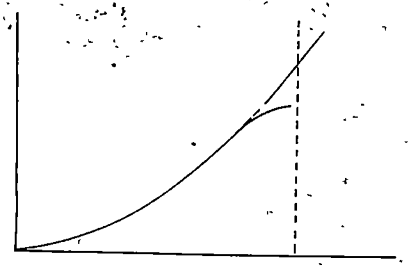

Fig. 3

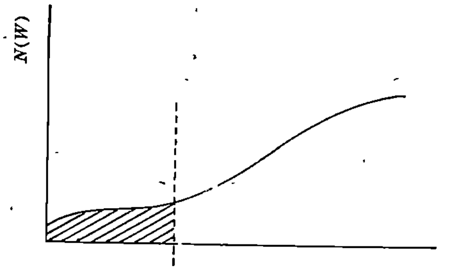

Fig. 4

consequence it has been possible to piece together the reduced Brillouin zones each containing $2N$ states into an extended k-space of the type described by Jones[6] (approximation of nearly free electrons). Since the energies are so close to the value for free electrons, the energy gaps on crossing zone boundaries are small, as shown in Fig. 3, and consequently d^2W/dk^2 is large. This means that the effective mass is small, as shown directly by the experiments, and consequently the density of states is small near one of these points (Fig. 4) This is why the number of electrons in a pocket is so frequently small; it is *not* very sensitive to the position of the Fermi surface, and though it can be changed by alloying another metal which affects the total number of electrons, it is not changed very much.

With the success of work of this kind we may be well on the way to the development of a quantitative theory of metallic properties, with a detailed description of the difference between individual metals. On the other hand, it is still possible that there is something lacking in the present theory, and that the shape of the Fermi surface calculated by refinements of the methods described will not agree with the experiments. Herein lies much of the interest of the work.

AUTOMATIC FUNDAMENTAL CALCULATIONS OF MOLECULAR STRUCTURE

By Dr. S. F. BOYS, Dr. G. B. COOK, C. M. REEVES and I. SHAVITT
Theoretical Chemistry Department, University of Cambridge

IN principle, it is possible to predict the structure and properties of molecules with unlimited accuracy merely from Schrödinger's equation and the numbers and properties of the electrons and nuclei defining the molecule. The complicated mathematical formulation, the very intractable intermediate probems and the extent of the numerical operations have caused this to be both a very confusing and a difficult subject. It does not appear to have been generally realized that the advent of automatic machines has simplified and made practical such calculations, not only as a means for performing the arithmetical operations but also for the carrying out of much of the mathematical analysis of the most formal type. It is hoped that this report and discussion of the results of some prototype calculations of this nature may help to demonstrate the significance and future possibilities of such calculations. The full description will be given elsewhere and will be somewhat lengthy ince it will include some theoretical developments which enable the solutions of the formal mathematical problems to be expressed in the form of procedures uitable for automatic performance. However, these are methods applicable to all molecules and, once stablished, need not be repeated or extended. These methods have been worked out with the facilities of the Mathematical Laboratory, Cambridge, to the Director of which, Dr. M. V. Wilkes, and staff we are much indebted. The procedures are in operation on the EDSAC, but could be applied to any general-purpose machine.

The force constants, etc., given below represent the final stages of some fundamental predictions of molecular properties. Their interest does not lie so much in the magnitudes found, as in the fact that they have been obtained using the EDSAC by procedures of the above type which could be applied to any molecule with unlimited accuracy. The machine has been caused to perform most of the organization of the calculations and a considerable portion of the mathematical analysis, as well as all the arithmetic. It is possible, though not certain, that more effort has been required for the development of these procedures than might have been needed for the calculations without automatic computation, but this initial effort is largely non-recurrent.

In Table 1 the force constant and energy were obtained (S. F. B. and G. B. C.) by evaluating the wave functions for the BH radical at three different internuclear distances. The wave functions were obtained as linear combinations of twenty-three co-detors by the variational method. The term co-detor is used

Table 1. Equilibrium Data for BH Radical

	Calculated	Experimental
Total energy	– 25·105	—
Binding energy	0 055	< 0 13
Bond length	2·33	2 33
Force constant	0·30	0 19

for describing antisymmetric functions in many variables which are formed from a set of elementary three-dimensional exponential polynomial functions ; first, by constructing orthonormal linear combinations of members of the set ; secondly, by using these combinations to form antisymmetric many-dimensional functions of the Slater-determinant type ; and thirdly, by constructing simple linear combinations of these determinants which transform as the irreducible representations of the group symmetry of the molecule under consideration. The method of calculation would converge to the true solution of the many-electron Schrodinger equation as the number of the elementary functions is increased and all co-detors corresponding to these are included.

All quantities are expressed in atomic units. The accuracies of the experimental binding energy and force constant are quoted by Herzberg as uncertain.

The EDSAC was used to calculate the numerical values of all the elementary integrals, to perform the various matrix transformations and linear combinations and to solve the eigenvector equation. This would naturally have been expected, but in addition the algebraic formulæ used for a large number of the most complicated integrals had previously been derived by J. L. Turner and S. F. Boys on the EDSAC. In essence, the machine had been caused to manipulate numbers as codes representing mathematical functions and to combine these according to the non-arithmetical processes corresponding exactly to the processes which one performs with the mathematical functions in the determination of an explicit formula for an integral of this type. The largest class of integrals for which this was performed was that of the so-called hybrid six-dimensional electrostatic integrals, some of which led to final formulæ involving more than five hundred terms. This particular application of the machine serves to emphasize the advantages—and, in many cases, the necessity—of handing over to the automatic computer many of those processes of formal mathematics that would generally be regarded as requiring considerable and unavoidable intellectual effort.

Table 2. EQUILIBRIUM DATA AND FORCE CONSTANTS FOR H_2O

		Calculated	Experimental (ref. 1)
Total energy		– 75·77628	– 76·4641
Binding energy		0·21350	0·3544
O—H distance (R)		1·95	1·85
H—O—H angle		96°	105°
Force constants	A_{11}	1·15	1·07
	A_{12}	– 0·09	+ 0·06
	A_{22}	0·22	0·20
	A_{33}	1 31	1·10

Table 2 shows corresponding data for a subsequent calculation on H_2O (S. F. B. and C. M. R.). This involved the solution of the wave equation at seven nuclear configurations. A total of ninety-six co-detors, formed from eight elementary orbital functions, was examined, but only about thirty of these contributed appreciably to the wave function and were retained for the final parts of the investigation. The total energy of distortion, δE, is given in terms of the O—H distances, r_1 and r_2, and of the H—O—H angle θ radians by :

$$2\delta E = \frac{A_{11}(\delta r_1 + \delta r_2)^2}{4} + 2A_{12}\frac{(\delta r_1 + \delta r_2)\,(R\delta\theta)}{4} + \frac{A_{22}(R\delta\theta)^2}{4} + \frac{A_{33}(\delta r_1 - \delta r_2)^2}{4}$$

The quantities $(\delta r_1 + \delta r_2)/2$, $R\delta\theta/2$ and $(\delta r_1 - \delta r_2)/2$ are convenient generalized co-ordinates.

In the course of this calculation, the use of the machine for carrying out formal mathematical and essentially non-arithmetical analysis was extended to cover a much greater part of the investigation than in the earlier work. The machine was provided with a list of the co-detors in coded form. It then considered every variational element which could arise and worked out its formula in terms of the single- and two-electron integrals. Previously computed numerical values were substituted automatically into these formulæ and the lowest eigenvalue and corresponding eigenvector of the resulting matrix evaluated to give the required energy and wave function.

It will be realized that after the first decisions have been taken concerning the number and form of the elementary functions, the whole calculation of the wave function, although it appears to involve about half a dozen separate mathematical processes, is in fact a perfectly determinate operation with a unique result which is not dependent on any further decisions. It is the aim of investigations such as these to enable automatic machines to perform the whole sequence of operations with the minimum of intermediate reference to the human investigators. Significant progress has been made towards this goal, although the possibilities of improvements are by no means exhausted.

The comparison of the theoretical and experimental results for the molecular dimensions and force constants (see Table 2) is considered quite satisfactory for the present stage of development. The sign discrepancy in A_{12} corresponds to a relatively smaller discrepancy in the direction of the principal axes of the potential energy quadratic form. In neither calculation were the best sets of elementary functions fully investigated, since the main effort was to put into operation the general calculation procedures, and it was considered that the results for any reasonable parameters would be valuable for future work. The binding energies were found as the difference of the total energies from the calculated energies for the separated atoms. For the comparison with experiment it was desirable to evaluate the force constants ; but it should be realized that in this direction the scope of the theoretical method far exceeds the experimental, since it gives directly the energy of distortion to any other configuration, not just the lower derivatives, which are all that can at the present be obtained from spectral analysis.

In the wave function calculation for H_3 (the activated complex of a reaction such as $D + H_2 \rightarrow DH + H$), which led to the values of the 'force constants' given in Table 3, the procedure followed was in principle the same as in the preceding calculations, with the exception of a new particular programme which enabled some complicated integrals to be evaluated about ten times as fast a previously. The whole calculation (by S. F. B. and I. S.) comprised the energy determination for nine different configurations of the nuclei around the transition complex. The activation energy quoted i the excess energy at the 'saddle-point configuration' which was found to be linear, over the calculated energy of a separate hydrogen atom and a hydrogen molecule.

It is valuable to include these results here particularly to emphasize that the type of calculatio which we normally call the determination of

Table 3. DATA FOR THE TRANSITION COMPLEX OF H_3

		Calculated
Total energy		− 1·628
Activation energy		0·025
H—H distance (R)		1·78
Force constants	A_{11}	0·288
	A_{22}	0 023
	A_{33}	− 0·05

molecular wave function is by no means restricted to the determination for an equilibrium configuration of a stable molecule; it is equally applicable to any configuration of atoms whether these represent a stable molecule, a distorted molecule or an arrangement of atoms in the process of reaction. The force constants in the latter case are, just as in the other cases, the co-efficients of a quadratic approximation to the potential energy in terms of relative nuclear co-ordinates. They cannot, of course, be observed experimentally as physical force constants; but they are necessary theoretical data if a prediction of the reaction-rate is to be made.

Here the total energy of distortion, δE, is given in terms of the H—H distances r_1 and r_2 and of the H—H—H angle θ radians by:

$$2\delta E = \frac{A_{11}(\delta r_1 + \delta r_2)^2}{4} + \frac{A_{22}(R\delta\theta)^2}{4} + \frac{A_{33}(\delta r_1 - \delta r_2)^2}{4}.$$

It may be emphasized that although these calculations were made with limited numbers of initial functions (seven for BH, eight for H_2O, six for H_3) and the final convergence is only obtained as these numbers are indefinitely increased, the number of functions in each case was greater than the minimum number which could have been used to give a meaningful result. The procedures would not have required any alteration if larger numbers of such functions were used.

Since the impression seems to be very easily given that the various co-detors used for these calculations correspond to excited states of the system or of some unperturbed system, it may be stated again that this is not so (see Boys[2,3]). Indeed, if functions corresponding, even approximately, to the excited states were used, there would be no ultimate convergence, and the convergence even for small numbers of terms would be very unsatisfactory. This point is illustrated most simply by the fact that the bound-state wave-functions of the hydrogen atom are not a complete system, and that the first few terms are completely unsatisfactory for accurate fitting of functions in the region of the low-energy wave functions. To say, as is sometimes done, that the inclusion of the unbound states would rectify this is not valid, since these do not constitute an enumerable system of functions and so are not applicable to form a complete system of functions in the ordinary mathematical sense, and are even more inconceivable in any practical sense. The situation is that, if the single electron functions are chosen in a manner which would lead ultimately to a complete system of functions (not necessarily orthogonal), then co-detors made from these will also be complete. Direct consideration of this desideratum of completeness, particularly in the physical regions where the wave function is large, is the most effective way which we know at present for obtaining low-energy wave functions (see Boys and Price[4]).

Since the most frequently cited calculations on molecular structure have been by means of the molecular orbital approximation, the relation of this to the present method will be indicated. The molecular orbital approximation signifies in its most exact sense the best approximation to the true wave functions which can be obtained by use of a function of the form of a single Slater determinant, and always retains a definite error. A direct application of this approximation to calculate a wave function involves the evaluation of as many difficult integrals as does the present method, but only obtains a less accurate result. It avoids some of the effort towards the end of the calculations, but this is not a very great economy over the whole calculation. This direct calculation has only been made in four or five cases and then generally with further approximations. On the other hand, the approach which is most frequently described as that of molecular orbitals, and which has been applied very widely, is the use of the approximate formula corresponding to a single determinant in a semi-empirical way in which the quantities on which it depends are not found by calculation, but are adjusted to give the correct answer for some particular molecules, and then these values used to make predictions for other molecules.

The present results must not be regarded as giving the best accuracy which can be obtained with the numbers of expansion functions cited. In fact, most of the effort has been devoted to the development of the general mathematical procedures and to the application of these to give the automatic programmes. In this connexion other workers would probably be interested to know the required machine time. It is very difficult to make any estimate which is not dependent on particular circumstances, but it is probable that, at the present stage of development for a machine obeying a thousand orders per second and having a store of about a thousand words, it would require about forty hours of machine time to produce one wave function for one configuration of the water molecule if a single run without any errors or any checking were possible.

Finally, it may be stressed that the programming of the formal mathematical procedures as well as the associated arithmetical operations offer one of the most stimulating possibilities for the solution of many problems of mathematical physics. This kind of approach appears extremely powerful for problems associated with electronic wave functions, and to have possibilities of even greater value for the complicated problems of nuclear wave functions, particularly for the heavy formalisms of the fractional parentage schemes of functions. On the other hand, the possible application of such methods to the more classical problems, for example, those in which the relaxation methods have been so widely used in desk calculations, should be thoroughly examined. The programming of machines to handle all the theory and arithmetic associated with formal expansions in non-orthogonal complete systems of functions would not be difficult. Such an approach for desk work is difficult owing to the necessary increased strain on the computer working at a higher mathematical level. In an automatic method the increased complication would only enter at the initial stage of making the master programme, and might easily present the more interesting problem.

INHERITANCE OF ACQUIRED CHARACTERS

THE problem of the inheritance of acquired characters is one that has exercised the minds of biologists since the days of Lamarck. That interest in this aspect of evolution is unabated was shown by the very full attendance at the joint discussion of the subject, between the Linnean Society and the Systematics Association, held in the rooms of the Linnean Society on November 1. The discussion was opened by Prof. H. Graham Cannon, who cited Leonard Doncaster's definition of an acquired character as "a feature developed during the life of the individual possessing it, in response to the action of use or environment". The added qualification that, "as a rule", such acquired characters were adaptive, has led to much of the trouble arising out of attempts to prove or disprove the proposition. There are two types of experiment, depending on the nature of the change in the environment to which the organism is subjected, whether normal, as occurring in Nature, or not. To the neo-Mendelian the distinction does not matter, for as Carter said, "It is easy to imagine a gene doing anything we want it to do". Every organism in equilibrium with its environment must change somehow if external conditions change. The difficulty is to force it to change obviously, and, as MacBride said, if a change from one environment to another causes a change in structure in one generation, a change in the opposite direction should reverse it in an equal time. This is true of adaptive acquired characters. If the acquired character is induced by some abnormal circumstance, it will be an induced mutation and therefore inherited in the normal Mendelian manner. It seems, therefore, that attempts to demonstrate experimentally the inheritance of acquired characters are a waste of time.

It is Lamarck's fourth law that states explicitly that acquired characters are inherited ; but this law is redundant as it is covered by his second and third laws. To Lamarck, it was not a question of a new character appearing in one generation and being handed on to the next. In accordance with his second law, it would appear in any event, because it was required. The present neo-Mendelian theory is based on the idea that, "New hereditary changes occur spontaneously and at random : they are not guided so as to fit the environment". This view was repudiated by Graham Cannon. Mendelian inheritance can go back only as far as the first Metazoa, since it depends on the orderly behaviour of chromosomes. Below that level, there is no true mitosis or meiosis, on which proof of the Mendelian law is based, and, at the best, only *simulacra* of these processes in the Protista. The earliest living matter was an amorphous protoplasm, a chemical mixture in equilibrium with its surroundings and, as such, must have reacted according to the physico-chemical law of Le Chatelier. The result would accord with Lamarck's second law. Protoplasm was able to adjust itself in the optimum manner to changes in its surroundings, and it was unlikely that when cells, sex and chromosomes appeared, this quality disappeared. This homœostatic property of protoplasm applied to the morphology as well as the physiology of the organism. It is the main motive force of evolution.

The problem of inheritance in bacteria was discussed by Dr. A. C. R. Dean. In such micro-organisms, the proportions of enzymes in the cell must attain stable ratios after long-continued growth in a given medium. When the medium is changed, different ratios become necessary and the adjustments are made during the lag phase before growth recommences in the new medium. Considerable growth in the new medium is required, before the ratios settle down again to a new stable value. In bacteria, growth and function are closely linked and response to changes in the environment is automatic. Another interpretation of the lag phase is that it represents the time taken by fully adapted mutants to multiply. Experiments with *Bact. lactis aerogenes* and D-arabinose, designed to test these alternatives, favoured the adaptation hypothesis. Thus, there is an increase of at least 40 per cent in cell mass before cell number increases. No stably adapted strains were obtained by plating out individual bacteria from cultures starting to grow in the new medium. Other tests, with different organisms, indicated that the majority of the cells in a culture undergo adaptation, whether the medium contained a new food material or a drug such as proflavine, streptomycin or chloramphenicol. The stability of an adapted strain depends on how well the training has been impressed on the cells and never seems to become absolute. Even after a thousand generations on drug media, the adaptation, although persisting in some cases for as long as six hundred generations on drug-free media, was eventually lost. The interpretation to be placed on these results is debatable. Dr. Dean inclined to the view that such adaptations represented the development of an existing function, rather than the acquisition of a new one. It is very doubtful to what extent they throw light on the position in multicellular forms.

In attempting to link up the situation in unicellular organisms with that in the higher plants and animals, Dr. R. Melville suggested that the initial changes in the cell were similar in all groups. They depended on the exploitation of existing enzyme systems and alternative metabolic paths. The first result in the higher groups was a phenotypic response, which was not inherited. Environmental changes may set up relentless pressures, and failure to adapt may mean extinction. The probable course of events was that after a variable number of generations, some essential molecule or molecules become attached to a protein molecule, possibly ribose nucleic acid. This may be contained in a cytoplasmic granule and have the properties of a plasmagene. It may pass from cell to cell and be carried over sporadically during fertilization. Afterwards, the plasmagene may be incorporated in a gene and pass into the nuclear mechanism for Mendelian inheritance.

The most critical stage in the suggested adaptive process was probably that leading to the formation of a transmissible particle. As evidence for the occurrence of this process, Waddington's work on the production of pheno-copies for cross-veinless, by subjecting puparia of *Drosophila melanogaster* to a temperature shock, was cited. Individuals inheriting the character were found from the twelfth generation onwards. In plants, it appeared from Darlington's work on male sterility in *Epilobium luteum* × *hirsutum* that plasmagenes restoring fertility appeared after fourteen generations. From knowledge of the physiology of pollen sterility in *Forsythia* and other plants, boron may be an important factor in the fertility mechanism. This linked up with the mineral content of the soil, as an example of an environmental factor that may exert an adaptation pressure. In discussing temperature, Crosby's paper on the "Role of Plasmogenes in Acquired Adaptations" was mentioned, and it was pointed out that no special assumptions were necessary if the applicability of the Le Chatelier principle were admitted. The effects of temperature were stated more precisely by the van't Hoff principle. It followed, that if a process was controlled partly by exothermic and partly by endothermic reactions, any change of temperature would have a differential effect. Applied to morphology, this could affect the shape of leaves or other organs. An explanation of the topocline in leaf shape in *Ulmus coritana* was possible, on these lines.

In the unavoidable absence of Prof. Waddington, his paper was read by Dr. A. J. Cain, who said that although random mutation and natural selection, together, constitute a mechanism or generating states of high *a priori* improbability, many people were not satisfied that this conventional theory contains the whole truth. The existence of environmentally adapted populations within a species could not be wholly irrelevant to the process of evolution. On general grounds, one would expect the capacity of an organism to respond to environmental stress to be under genetic control. Individuals within a population will vary in this respect and natural selection will favour those in which the response is greatest. Conditions for producing, experimentally, a really adaptive change in an organism had not been devised, but artificial selection could be applied to other environmentally induced responses. When *Drosophila* puparia are subjected to a hot shock, some individuals respond by developing abnormalities in the wing venation. After twelve generations, cross-veinless flies began to appear in untreated individuals. When these were bred together, without further treatment, strains could rapidly be built up, in which nearly all the individuals were cross-veinless. The original phenotypic response was now genetically fixed. Similar results were obtained with populations from different sources. In most wild-type stocks submitted to temperature shock, four types of abnormality occurred. If selection is practised on any one of these, its frequency increases, while that of the others does not. In generalizing from these experiments, it seems possible for a response, that was at first only imperfectly adaptive, to be 'tuned' more closely to the requirements of the animal's life. The mechanism revealed operates in a perfectly 'orthodox' Mendelian way. The most important question remaining for discussion is how it comes about that so many responses of animals to environmental stresses are adaptive. The answer may be based on two considerations. First, that development must be epigenetic, involving interactions between parts, so that, for example, changes in the skeleton are associated with changes in musculature, and *vice versa*; secondly, that selection acting on a macro-evolutionary time-scale will tend to favour types of epigenetic interaction that offer the possibility of adaptive response to stresses.

In the general discussion following, Dr. W. B. Turrill criticized Prof. Graham Cannon for his statements that bacteria had "no nucleus, no chromosomes and no sexuality". Dr. M. L. R. Petterson directed attention to the evidence, published in recent text-books, for the existence of genes in both bacteria and viruses, and Mr. P. F. Mattingly mentioned a very beautiful experimental demonstration by certain French workers of the existence of a linear arrangement of hereditary factors in *Escherichia coli*. Prof. Graham Cannon questioned the validity of work with bacteria kept in culture for considerable periods, and suggested that infection by viruses might affect the results. Dr. Dean admitted that the stocks employed had been in culture some years, but their behaviour was always tested in a standard medium before and after experiments with drugs or alternative carbon sources. Dr. S. M. Manton regretted that the discussion had centred so much around single isolated characters. Many characters are intimately correlated for the harmonious working of a whole animal. For example, the control of movement in a centipede involved nearly all parts of the body, and a change in a single character would be ineffective. The number of simultaneous gene changes necessary to account for tergite heteronomy in the centipedes is so prodigious that the concept needs reconsideration.

R. Melville

OBITUARY

Sir Gerald Lenox-Conyngham, F.R.S.

The working life of Colonel Sir Gerald Ponsonby Lenox-Conyngham, who was born at Moneymore, Londonderry, on August 21, 1866, the fifth son of Sir William Lenox-Conyngham, and educated at the Edinburgh Academy and the Royal Military Academy, Woolwich, may be reckoned from the time of his being commissioned second lieutenant, Royal Engineers, at the early age of nineteen. Even after his ultimate retirement sixty-two years later, he continued, until his death on October 27, to be the valued counsellor of his friends. The first half of his long career was in India; the remainder in Cambridge. Throughout he was sustained by Lady Lenox-Conyngham, whom he married in 1890. She was daughter of Surgeon-General Sir A. E. Bradshaw, and there was one daughter of the marriage.

An orderly line of progress throughout may be perceived. Lenox-Conyngham joined the Survey of India in 1889 and was then engaged on astronomical field-work for the next dozen years. During 1894–96, as partner to Burrard (later Sir Sidney Burrard), his senior by five years, he was on deputation out of India conducting observations for the precise longitude of India, then embarrassingly in doubt. These two great men—for they were of great stature and of equally notable ability—became and continued fast friends; but they ever remained to each other just 'B' and 'C'.

The longitude at Karachi which they found was closely confirmed thirty years later by observers of the 1926 International Longitude Project, who had manifold advantages of developments such as wireless telegraphy.

Local arrangements for two solar eclipse parties visiting India in 1898 were entrusted to 'C'. At one of the camps he met H. F. Newall, professor of astrophysics at Cambridge, and formed with him a lasting and fruitful friendship. Then came some years of precise latitude field-observations from which deflexions of the vertical—the *direction* of gravity—are derived. 'B' was then seeking the cause of these and previously found deflexions: extra observational evidence, in the form of the force of gravity, was needed.

Thus in 1902 a gravity survey was planned. 'C' was delegated to Europe to examine, acquire and standardize the best available pendulum equipment; and two years later he took to India a set of four brass von Sterneck half-second pendulums. The next few years, during which I was fortunate in being associated with him, saw the beginning of the series of observations which had nearly covered India and Burma before the Second World War. A great difficulty with brass pendulums in field-survey is finding the temperature of the pendulum shaft. 'C' went far to meet this by his 'dummy' pendulum, the shaft of which contained a thermometer. Later he proposed invar pendulums, but was dissuaded by reason of the magnetic susceptibility of invar. Nevertheless, subsequent pendulums have usually been made of invar.

In 1912 he became superintendent of the Trigonometrical Survey. He was an excellent administrator —a firm but sympathetic and trusting chief. Absence of disorder and steady progress of work in hand were apparent in offices where he was in charge, whether field-party or directorate. The onset of the First World War frustrated his natural promotion to surveyor-general; for the services of Sir Sidney Burrard were extended for the duration of the war. Thus Lenox-Conyngham retired as superintendent in 1920, having been elected a Fellow of the Royal Society in 1918 and received the honour of knighthood in 1919.

In 1898 Prof. Newall had had a close view of the then greatest existing practical geodetic organization; and he felt strongly that geodesy, neglected in Britain, should be promoted. So at a well-chosen time he used his great powers in that direction. Only a month ago, at a luncheon given in Trinity College by friends to Sir Gerald and Lady Lenox-Conyngham to mark their attainment of the tenth decade, Sir Gerald made a remarkable speech; and he recounted how after return to England in 1920 he had received a letter from the then Master of Trinity, Sir J. J. Thomson, asking him if he would accept a praelectorship in geodesy coupled with a fellowship of Trinity, and with what satisfaction he assented.

The formation of a School of Geodesy involved especial difficulties for a newcomer to the University; but his charming presence and shrewd sense inevitably prevailed. The School was formed, and later in 1931 was expanded into the Department of Geodesy and Geophysics. Geodetic and topographical surveying became one of the four subjects for the Geographical Tripos, and the School became the training centre for most of those who later became the principal survey officers of the British Colonial Empire. Meantime, the University created a readership in geodesy and appointed Lenox-Conyngham to it, having previously conferred on him the degree of M.A.

During this second career, he attended all the general assemblies of the International Union of Geodesy and Geophysics, from the first at Rome in 1922 to the sixth at Edinburgh in 1936. He also represented H.M.'s Government at the second and third Pacific Science Congresses in Australia in 1923 and Japan in 1926. The inhabitants of Montserrat, Windward Islands, alarmed at the increasing frequency of earthquake shocks, petitioned the Governor to obtain scientific opinion as to their security. So the Council of the Royal Society, consulted by the Colonial Office, invited Lenox-Conyngham to visit the neighbourhood and to investigate the seismic circumstances; this he did in 1936. He gave some account of this in a Friday Evening Discourse at the Royal Institution on March 12, 1937. He also served on the Council of the Royal Society for the periods 1920–21 and 1934–36.

Lenox-Conyngham had become the father of British geodesy. Recently, he received the affectionate greetings and congratulations of the International Association of Geodesy; and his death, inevitable though it be, is a lively sorrow to a wide international circle.

J. DE GRAAFF-HUNTER

NEWS and VIEWS

The New Scientist

THE interpretation of scientific research and discovery to those who have had no special scientific training and especially to people who have practical interests in the applications and implications of science is now a fundamental need in any country. This need is well met in the United States through *The Scientific American*; somewhat similar journals are published in various countries on the Continent of Europe, and recently one dealing with science for the layman has been launched in India. In this respect, Britain has been backward, although it has several excellent journals of more 'popular' appeal, and frequently newspapers and general popular journals carry excellent interpretative scientific articles. Yet in spite of this there have been repeated calls from industrialists and others, who have realized the need for men and women other than the scientists themselves to understand at least the aims and objectives of research, for a medium which will meet their needs. The very idea, therefore, of such a journal in Britain is welcome, and now it has become manifest in the issue on November 22 of the first number of the weekly periodical, *The New Scientist* (Cromwell House, Fulwood Place, High Holborn, W.C.1).

The aim of this journal is to appeal to all who are interested in scientific discovery and its impact on, and utilization in, industry, commerce and society in general. There are many such people to-day, for the impacts of science are many and profound. It is at last realized that Britain badly needs many more and better trained scientists and technologists; but it can scarcely be expected that such needs will become satisfied or even that the best efforts will be made to meet them until leaders in industry, commerce, politics and even education itself are better informed concerning things scientific. This can only be done by a journal which is free from scientific technicalities and jargon; and this is the style admirably adopted by *The New Scientist.* For the first issue, the Editor has selected some authors who are not only well known among scientists for their contributions to the advancement of science in various fields but are also able to interpret their work in an intelligible and attractive way to readers who have not been trained in scientific discipline. These authors include the President of the Royal Society (Sir Cyril Hinshelwood), Sir Edward Salisbury, Prof. Zdenek Kopal and Dr. N. A. Mackintosh. There are eight such articles, and each is well worth reading not only by the non-scientist but even by scientists themselves. Apparently we are also to be presented with a series of scientific profiles; Sir Edward Appleton figures in the first issue—an apt choice especially since he is giving the present series of B.B.C. Reith Lectures. Among other features of this excellent first issue are science news from the home front, from the United States and from elsewhere overseas; letters to the Editor; book reviews; and city comment. This last section will appeal particularly to city business men who are specially interested in commercial and industrial projects based directly on scientific discovery.

The New Scientist has made a good start. No doubt it will maintain the high standard which it has clearly set itself, thus becoming a very important and welcome addition to British periodical literature.

Numbers of Science and Technology Students in Britain

FIGURES for full-time students taking a course for a first degree in science or technology in institutions in receipt of Treasury grant, given by Mr. H. Macmillan in a written reply in the House of Commons on October 23, indicate that in pure science the numbers increased from 5,897 in the academic year 1938–39 to 13,916 in 1951–52 and thereafter declined slightly to 13,485 in 1953–54. In technology the trend was the same: an increase from 3,836 in 1938–39 to 7,590 in 1951–52 and thereafter a decline to 7,439 in 1953–54. The number of first-, second- and third-year students in pure science in 1938–39 was roughly just over 1,800 in each year, and in 1953–54 was again approximately equal—at 4,100–4,300; but the number of fourth-year students, which rose from 396 in 1938–39 to 1,449 in 1951–52, fell to 755 in 1953–54. In technology the variations between the different years became greater: in 1938–39 for first-, second- and third-year students the figures were 1,391, 944 and 1,193, respectively, and in 1953–54, 2,286, 2,240 and 2,031; fourth-year students rose from 276 in 1938–39 to 1,149 in 1951–52, and the number in 1953–54 was 758. Students taking a fifth or later year in technology numbered 32 in 1938–39, 161 in 1952–53, and 126 in 1953–54. An appendix to the ninth annual report of the Advisory Council on Scientific Policy since issued gives the number of first degrees in pure science in 1954–55 as 4,938 compared with 2,167 in 1938, 5,577 in 1951–52, 5,379 in 1952–53 and 5,096 in 1953–54. Of these, 1,886 were pass degrees; and of the honours degrees 914 were in chemistry, 600 in physics, 494 in mathematics, 403 in biological sciences and 122 in geology and related sciences; for 1951–52, the peak year, the corresponding figures are 2,232; 977; 608; 553; 464; and 144, respectively. First degrees in technology in 1954–55 were 2,314, of which 1,005 were pass degrees; for 1938–39 the corresponding figures were 1,048 and 516; for 1951–52, 2,765 and 1,186; for 1952–53, 2,578 and 1,155; and for 1953–54, 2,336 and 1,036.

Patents Bill

IN moving the second reading of the Patents Bill in the House of Lords on November 22, Lord Mancroft said that when the Patents Act, 1949, was drafted it was envisaged that, on the restoration of normal peace-time conditions, the Patent Office examiner would make his first report about three months after the complete specification was filed, and that nine months would be a reasonable allowance for the remaining steps to be taken. It was hoped that the arrears of unexamined specifications which had accumulated during the War would soon be cleared, and accordingly the average of the pre-war time limit was adopted and the period made twelve months with an optional further three months on payment of a fee. The intake of patent applications, however, is nearly 40 per cent above the pre-war average of about 21,000, and is still increasing; and with the general shortage of science graduates the Patent Office is unable to recruit enough examiners to keep abreast of the intake. The present examining staff of about 340 (compared with 310 before the War) is expected by special efforts to dispose of nearly 26,000 complete specifications in 1956, leaving an excess of at least 3,500 on the year. There are large arrears of unexamined applications, and it is unusual for the examiner's first report on an application to go out until more than twelve months after the complete specification is filed, leaving no time for the applicant to meet any objections raised by the examiner. The Patent Office is using powers conferred on the Comptroller, under the Emergency Act of 1939, to grant extensions, and the new Bill authorizes the Board of Trade to prescribe from time to time the period during which an application must be put in order for acceptance, subject to the limits that this period must not be less than one or more than four years. The Bill also continues the existing provision of the 1949 Act for allowing the applicant an additional three months on payment of a fee. Replying to questions about staff, Lord Mancroft said that action has been taken to attract graduates and undergraduates to a career in the Patent Office. The salary scale has been revised, and recruits now start at £605, on a scale running up to £1,345, and leading after promotion up to £2,000. Lord Mancroft added in conclusion that it is important not to lower the standard of either the examiners or the patent procedure.

Grants from the R. W. Paul Instrument Fund

THE Royal Society announces that grants have been made by the R. W. Paul Instrument Fund Committee as follows: £2,000 to Prof. R. V. Jones and Dr. A. H. S. Holbourn, University of Aberdeen, for continuation of the development of an engine for ruling diffraction gratings in which, in order to avoid the difficulty of making an almost perfect screw, use is made of light waves to determine the grating space; £1,500 to Prof. S. Devons, University of Manchester, for an investigation of the proposed optical system of a new type of reflecting camera incorporating a correcting lens and furnishing increased speed and field of view—a camera which could be used in an investigation of the structure of weak extended sources of light in interstellar space of the Milky Way. The Paul Instrument Fund Committee, composed of representatives of the Royal Society, the Physical Society, the Institute of Physics and the Institution of Electrical Engineers, was set up in 1945 "to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much-improved types of physical instruments and apparatus for investigations in pure or applied physical science".

Early Life of George Boole

SIR GEOFFREY TAYLOR, whose mother was one of George Boole's daughters, contributes to *Notes and Records of the Royal Society*, 12, 1, an article on Boole's early life and mathematical studies. Previous accounts have not always been consistent one with another, nor entirely free from unwarranted speculation. Some interest is attached to these questions, since Boole's work on symbolic logic, first expounded in his "Mathematical Analysis of Logic" (1847) and developed more fully in his "Laws of Thought" (1854), is marked by profound originality of concept; it gave one of the earliest instances of an algebra differing substantially from the familiar algebra of real numbers, and thus not only opened the way to a new field of applications, but also contributed largely to the development of modern ideas on the axiomatic foundations of a variety of abstract algebras. It is possible that this originality was fostered by the resolute manner in which Boole taught himself mathematics, and that the months spent in surmounting difficulties which might have been cleared away in a few minutes by contact with a competent teacher were not entirely a waste of his time, but played a considerable part in forming a powerful and precise research mind. In the same issue of *Notes and Records*, W. Kneale discusses Boole's algebra of logic and its place in the history of mathematical logic.

The Physics and Chemistry of Solids

A NEW journal, *The Physics and Chemistry of Solids*, has been added to the international series published by the Pergamon Press (London: Pergamon Press, Ltd., 1956. 42*s*. each part. Subscription rates per volume (4 parts): (*A*) £6; 17 dollars); (*B*) for individual subscribers certifying that the journal is for their private use, £2 15*s*.; 7.50 dollars). Prof. Harvey Brooks is editor-in-chief; in his foreword to the first issue, a combined issue for September and October 1956, he defines the fields of physics and chemistry for which the journal is to cater. They are, first, the electronic structure of solids and those physical and chemical properties deriving from that structure; and secondly, the statistical mechanics of condensed systems. Fundamental studies will be preferred to applications; but papers on borderline subjects will, apparently, be welcomed rather than discouraged. The first issue sets a high standard, and the editors, who are drawn from the United States, the U.S.S.R., Holland and France, will secure a prominent position for the journal if they are able to maintain that standard over the years; the advisory board, which includes the names of many whose contributions have greatly helped the advance of the understanding of the solid state, should ensure a steady flow of papers. The topics most to the fore in the first issue are magnetic properties, the absorption spectra of impurities in silicon, energy band-structure and residual resistivity. Two papers in particular contain good reviews of their parts of the subject—a feature which will be frequently required if the editors' aim of developing lines of communication between physicists and chemists is to be fulfilled.

Archæology in India

THE October issue of *Man* contains an interesting article by Dr. F. R. Allchin on certain stone alignments in southern Hyderabad. Stone alignments are found at many times and in many parts of the world, and there is not necessarily any reason to suggest cultural connexions between them. In Hyderabad they only occur to the north of the Krishna and Tungabhadra Rivers in the Raichur, Gulbarga, Nalgonda, Mahbubnagar and Atraf-i-Balda districts of the State. They consist of parallel lines of standing stones set out accurately. In all cases the lines seem to be oriented on the cardinal points. It is suggested that their age is late B.C. or early A.D. In the same issue is an interesting article by Prof. Robert Heine-Geldern on the coming of the Aryans and the end of the Harappa civilization in India. It is illustrated with a number of drawings of tools and seals. Prof. Heine-Geldern is convinced that the invaders arrived between 1200 and 1000 B.C., a date somewhat later than that usually suggested and much later than the one indicated in the subsequent (November) number of *Man*. The early archæology of the region from Quetta in Baluchistan right across northern India continues to excite great interest, and some day a firm date for the various cultures found will be finally determined.

Alexander Graham Bell Museum, Nova Scotia

THE Alexander Graham Bell Museum, which the Canadian Government has established to illustrate the scientific achievements of the inventor of the telephone, was opened on August 18 at Baddeck, Nova Scotia, where Bell spent his summers for more than thirty years and participated in early aeronautical research. The Museum is sponsored by the Department of Northern Affairs and National Resources, and its purpose is to protect and display the numerous relics of Bell's research that have been given to the Canadian Government. Kites, propellers and other objects indicate the experiments in heavier than-air flight which Bell carried out between 1890 and 1909, while other material illustrates his investigations in medicine and electrical and marine engineering.

The Industrial Research Associations in Grea Britain

THE Department of Scientific and Industrial Research has issued an admirably illustrated accoun of the work of the industrial research associations in the government scheme in a booklet entitled "Combining for Research: the Work of the Industria Research Associations in the Government Scheme" (pp. 32+16 plates; from the Department, London 1956). The booklet outlines the nature of the research associations as well as describing the various types o work carried out, and includes brief notes on th individual research associations. While in no wa critical, and making no attempt to assess the relativ importance or value of the different activities, i indicates very clearly the potentialities of co-operativ research as well as the conditions which must b fulfilled for effective work.

United States Awards for Further Study by Science Teachers

The National Science Foundation, Washington, D.C., is offering a new programme of fellowships for improving the teaching of science, mathematics and engineering in American colleges and universities. About a hundred fellowships will be awarded next March to citizens of the United States who hold a baccalaureate degree or its equivalent, have demonstrated ability and special aptitude for teaching science, have taught full-time at the collegiate level for not less than three years, and who intend to continue teaching. Selection will be based on letters of recommendation, academic records, and other appropriate evidence of professional activity and competence. The value of the fellowships will vary, but the total income must not exceed 10,000 dollars a year; travelling and other expenses will be allowed. Fellows may study for 3–15 months at any accredited non-profit institution of higher education in the United States or abroad. Application must be made before January 14 to the Division of Scientific Personnel and Education, National Science Foundation, Washington 25, D.C., from which further information can be obtained.

University of Hull

It is announced from the University of Hull that Prof. E. B. Castle, professor of education and director of the Institute of Education, has been appointed pro-vice-chancellor for a period of three years. Dr. Paul Galambos has been appointed lecturer in statistics in the Department of Economics and Commerce. Mr. B. Thomas has been appointed to a research studentship in the Department of Physics for work on radiation damage. The Medical Research Council has made a grant of £600 per annum for a period of three years to assist research work on the biosynthesis of the alkaloids of plants in the Department of Botany under the direction of Dr. B. T. Cromwell; Mr. K. Rothwell has been appointed to a research assistantship in the Department to undertake this work. The Research Section of the Shell Petroleum Company has made a grant of £1,000 to finance a research appointment in the Chemistry Department over a period of two years from the ession 1957/58.

University of London

The following announcements have been made by the University of London: Dr. I. M. P. Dawson, ecturer in pathology in the University of Leeds, has een appointed to the University readership in athology tenable at Westminster Medical School. The title of reader in physiology has been conferred on Mr. R. D. M. I.-K. Harkness in respect of his ost at University College, and that of reader in mathematics on Dr. K. F. Roth, in respect of his ost at University College.

Announcements

Dr. O. G. S. Crawford, founder and editor since 1927 of *Archæology*, and formerly archæology officer of the Ordnance Survey, has been awarded the *Verdienstkreuz* (first class) of the Federal German epublic, for his services to archæology.

Prof. T. S. Wheeler, professor of chemistry in University College, Dublin, will be going to the nited States on a lecture tour during January-March 1957.

Mr. George Brearley, a partner of Cremer and Brearley, consulting chemical engineers, and formerly managing director of Brotherton and Co., Ltd., has been appointed director of the Association of British Chemical Manufacturers in succession to Mr. J. Davidson Pratt, who is retiring in June 1957.

The Ministry of Supply announces that Dr. A. W. Lines has been promoted to deputy chief scientific officer and appointed senior superintendent, Research and Assessment Division, Guided Weapons Department, Royal Aircraft Establishment, Farnborough.

The following officers and new members of council for 1956–57 of the Institution of Civil Engineers have been announced: *President*, H. J. F. Gourley; *Vice-Presidents*, Sir Arthur Whitaker, Prof. A. J. S. Pippard, A. C. Hartley, Sir Herbert Manzoni; *New Members of Council*, R. J. Ashby, J. F. A. Baker, F. E. P. Clear, D. K. Duff, J. E. Dumbleton, Dr. L. F. Loder, F. J. Oliver and W. L. Owen.

The Royal Agricultural Society of England offers annually a medal together with an award of one hundred guineas for research work of outstanding merit carried out in the United Kingdom which has proved, or is likely to prove, of benefit to agriculture. Recommendations for the next award, by the heads of university departments, research stations and institutes and other research establishments, must be submitted to the Secretary, Royal Agricultural Society of England, 35 Belgrave Square, London, S.W.1, not later than January 31, 1957.

Prof. V. B. Wigglesworth, Quick professor of biology in the University of Cambridge and director of the Agricultural Research Council Unit of Insect Physiology, will deliver the fourth Middleton Memorial Lecture in the Wellcome Building, 183 Euston Road, London, N.W.1, on December 6, at 5.30 p.m. He will speak on "Insects and the Farmer".

The Institution of Naval Architects is offering the following scholarships, which are tenable for three or four years, according to the length of the course at the university or college selected: Trewent (naval architecture), £175 per annum; age limit, twenty. Parsons and Yarrow (marine engineering), each £175 per annum; age limit, twenty-one. All three are limited to British subjects. Further particulars can be obtained from the Secretary, Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1.

The autumn meeting of the Physical Society is being held this year in the Department of Natural Philosophy, University of Edinburgh, during December 17–19, and the general theme is "β- and γ-Ray Spectroscopy and Related Topics". During the meeting, on December 18, Prof. P. I. Dee, of the University of Glasgow, will deliver the eighth Rutherford Memorial Lecture of the Society; he will speak on "The α-Particle".

The first Technical Convention of the Institution of Telecommunication Engineers (New Delhi) will be held on December 30 at the National Institute of Sciences Hall in New Delhi. It will be preceded by the annual general meeting of the Institution on December 29, when Brig. Iyappa, the retiring president, will induct the president-elect, Prof. K. Sreenivasan, head of the Department of Electrical Communication Engineering, Indian Institute of Science, Bangalore.

The Institution of Chemical Engineers has now moved to 16 Belgrave Square, London, S.W.1.

ELECTRON TRANSPORT IN METALS AND SOLIDS

CONFERENCE IN OTTAWA

AN international conference on "Electron Transport in Metals and Solids" was held in Ottawa during September 10–14. The meeting was arranged by Dr. D. K. C. MacDonald, of the National Research Council of Canada, and was supported by the International Union of Pure and Applied Physics, by Unesco, and by the National Research Council. The décor of the meeting—the National Research Council Laboratories, overlooking the wide Ottawa River—was much appreciated by the fifty or so participants. By skilfully rebutting all attempts to include too many persons and too many papers, Dr. MacDonald and his assistants kept the programme within bounds, allowing time for proper consideration of the main topics and discussion of the problems still unsolved. One could wish that all scientific conferences were organized so sensibly, and not made indigestible with a gobble of successive pemmican pellets of condensed yet incoherent discourse.

A full account of the proceedings is to be published as a special number of the *Canadian Journal of Physics*. The following notes summarize (in logical, but not chronological, order) the main subjects.

J. Bardeen opened with a survey of the state of knowledge on interactions between electrons and lattice vibrations, leading to a lively discussion of the causes and effects in the lattice-scattering part of the resistivity of metals. It seems that, with corrections to the Bloch theory, this problem is now understood in principle, but detailed calculations of the resistivity of even simple metals are only now beginning to look reliable. The effects of deviations from equilibrium in the phonon distribution were discussed by E. H. Sondheimer, with reference to recent observations on resistivity and thermoelectric phenomena at low temperatures. G. Borelius pointed out that the resistivity of pure metals at high temperatures can be correlated phenomenologically with other properties; it appears that there may be much to learn from measurements of conductivity of liquid metals. The relation between X-ray scattering and electron scattering by lattice waves was developed by Sir K. S. Krishnan in an ingenious argument.

A review of electrical transport phenomena in alloys, by J. Friedel, brought out the wide variation of behaviour found with various transition elements, both in large and small concentrations, but most of the facts could be correlated reasonably well with theory. More controversial was the discussion concerning the minimum (and sometimes, also, the maximum) in resistance found at low temperatures in metals containing certain impurities. Papers by C. J. Gorter, by R. W. Schmitt and by J. Korringa showed the complexity of the phenomenon and the perplexity of its interpreters. It seems that there may be two distinct mechanisms, one related to an antiferromagnetic ordering in the spins of *d*-electrons in impurities from the transition group of elements and the other, not yet understood, which seems to require some sort of energy-level very near the Fermi surface of the matrix metal.

P. G. Klemens gave an account of the calculation of the electrical resistance due to lattice imperfections in metals. Although some reasonable estimates can be made for the scattering by dislocations, there are still difficulties in explaining the large changes in resistance caused by cold work in metals. An interpretation in terms of scattering by bands of stacking faults was supported by A. Seeger; but in the discussion other speakers found difficulty in believing that this effect could be large.

More fundamental problems concerning the validity of the Boltzmann equation, and the corrections one could make to it, were discussed by I. Prigogine, who outlined recent work on the statistical mechanics of irreversible processes. It is hoped that by starting from the 'master equation', more refined calculations may shortly be possible. Within the framework of the Boltzmann equation, it was shown by J. M. Ziman that there is a close connexion between the thermodynamics of irreversible processes and the variational principle of Kohler, which may be exploited to simplify calculations of transport coefficients. Another variational principle for conduction phenomena in the presence of a magnetic field or asymmetric scattering mechanism was proposed by A. Seeger, and R. Kubo gave a general expression for the conductivity tensor, derived directly from dispersion theory applied to the density matrix.

In reporting measurements on the electrical and thermal conductivity of metals, K. Mendelssohn emphasized the interest of thermal conduction in superconductors, which is effectively pure lattice conduction (although C. J. Gorter pointed out that the two-fluid model could be interpreted in such a way as to lead to an appreciable contribution from a circulation of normal and superfluid electrons) Information from lattice conduction could, as pointed out by P. G. Klemens, supplement electrica measurements in identifying the various types o imperfections in metals. Other experimental data were given by G. K. White, reporting on work in progress at the National Research Council Laboratories.

Nuclear magnetic resonance and the electroni structure of conductors was the subject of a review by N. Bloembergen. It is evident that measuremen of the Knight shift yields very diverse information some of which may be related to band structure o to known transport properties. There seems room for better correlation between this study and measurements of the more traditional transport parameters On the theoretical side, D. Pines brought up to dat the theory of plasmons, showing that in most solid the valence electrons form a plasma the collectiv oscillations of which have important effects. Th calculations are in remarkably good agreement wit experiment. It was suggested that, where there ar present both holes and electrons, as in a sem conductor, there may be new forms of excitation having dispersion properties like those of a soun wave; these 'distinct electron modes' may b literally named 'demons'. The various techniques b which direct information can be obtained about th geometry of the Fermi surface were described b R. G. Chambers. Cyclotron resonance, the anomalou skin effect, and the de Haas – van Alphen effect ca all show up anisotropy, and attempts are being made to interpret the results quantitatively.

Although largely devoted to the study of metals, the conference spent some time on topics related to semiconductors. N. F. Mott presented his theory of the transition to metallic conduction in semiconductors, regarding electronic transport in an impurity band as the jumping from site to site with activation by lattice vibrations. P. R. R. Aigrain, on the other hand, preferred a collective picture, in which the randomness of the distribution of impurity sites plays an important part. He suggested that certain states, although not localized, cannot carry current, and hence explained the low mobility in the impurity band. Experimental data on galvanomagnetic effects in *n*-type InSb at 4° K. were given by H. P. R. Frederikse. By considering valence bonds in various compounds, E. Mooser and H. W. B. Pearson were able to present some rules which allow the prediction of semiconducting properties.

An important contribution was made by A. F. Joffé, who discussed recent Russian work on heat conduction in semiconductors. Besides lattice conduction (which may be reduced very effectively by using mixed crystals so that phonons are scattered by the random distribution of atomic mass), there is a significant electronic contribution, and also a further part which may be due to transport of heat by excitons. This led to considerable discussion, with opinions divided as to the exact interpretation.

J. M. Ziman

GAS TURBINE DEVELOPMENT

The Engineering Department of the North Herts Technical College, Letchworth, arranged a conference on "Gas Turbine Development", which was held during October 20–21. It attracted more than a hundred, most of whom were leading designers or research workers in the appropriate field.

The first of the four main papers was given by Mr. G. B. R. Feilden, engineering director, Messrs. Ruston and Hornsby, Ltd., who offered a brief résumé of the development of the Ruston and Hornsby gas turbine (750/1,000 kW.), since 1946, dealing particularly with the engineering difficulties which were experienced in putting the research designs into working order. At the end of 1,500 hr. running experience with this machine, it was decided to go ahead with a production model capable of 750 kW. and rising to 1,000 kW. maximum output. Improvements were made in the prototype output by raising the maximum temperature, and increasing the length of the turbine blades by 7–8 per cent; production economy being maintained by utilizing tooling for existing blades. It was decided, also, to improve the matching of the components and make minor adjustments to the burners. The completed model had a compressor and turbine practically identical with the prototype, though epicyclic gears had been introduced and the turbine mounting improved. In order to enable the individual components to be serviced easily, however, considerable modifications in layout had been incorporated.

Mr. Feilden illustrated developments in the more recent installations, including one at Milan, which has now been in continuous operation for 10,000 hr. This machine is fired by natural gas, and the arrangement of the combustion chambers with ancillary ducting has proved very practicable for servicing. He also illustrated the installation at Debden, in which the heat exchanger is placed below the set, and the combustion chamber is arranged at an angle downwards. This is a coal-tar fuel-burning set with the ducting arranged upwards. Another slide showed the installation at the Admiralty Test House at Pyecroft, which was made to exacting specifications, the air inlet in this installation being at an unusual angle, and the ducting was woven through the installation. The turbine is to be fitted with a heat exchanger made of corrugated steel plates in the near future.

Mr. Feilden concluded his address by comparing the overall efficiencies of various plants required to produce both power and process steam. The Diesel is the most efficient power producer, and, for a 1,000-kW. electrical output, used in conjunction with an exhaust heat boiler, it gives better figures than any other plant for outputs of process-steam up to 7,500 lb. per hr.; above that requirement, the gas turbine is better. An exclusively steam plant, even with a highly efficient steam turbine and a high-pressure water-tube boiler, is far behind in overall efficiency, and only begins to be competitive if a very considerable quantity of steam (more than 20,000 lb. per hr.) is asked for.

Discussion revealed that problems of servicing under varying climatic and atmospheric conditions have been extremely interesting. While the installation at Kuwait has to digest large quantities of sand, this appears to have no adverse effect upon the turbine blades. The sodium sulphate in airborne particles presents an entirely different problem with the Milan installation, and it is necessary to wash the blades every 200–300 hr. with a solution of 'Teepol' and water; the turbine has now done 3,000 hr. non-stop.

"The Marine Gas Turbine" was the subject of the second paper, by A. W. Pope, chief gas turbine engineer, Messrs. W. Allen, Sons and Co., Ltd. Mr. Pope showed that there are two distinct applications of the marine gas turbine—naval and merchant-marine. In connexion with naval applications, there are many differing requirements. Naval can be divided into two categories: (*a*) protection of convoys, and (*b*) task forces. The former duty is performed mainly by frigates, a comparatively new class of ship of which there are various types (fast escort, anti-submarine, anti-aircraft and air direction). The task force duties are undertaken by aircraft carriers and cruisers. The varying requirements mean that aircraft carriers spend much of their time at full power, whereas frigates spend very little. On one such ship, it was found that 70 per cent of full power was used for only 1 per cent of the ship's life. There is here an obvious application for gas turbines (known as boost turbines) to provide the extra power when required. Already two British ships have been provided with such turbines, and an American ship is powered by 9,000 steam h.p., and 21,000 gas turbine h.p., with a saving of 20 per cent on engine weight.

Gas turbines are also being used for electrical generation. There are two types of generator set, namely, emergency and base-load. In emergency sets, fuel consumption is unimportant, and the gas turbine correspondingly simple. Mr. Pope gave an example of the development of such a turbine, detailing various changes in design to give greater efficiency.

Of base-load generator sets, he said that these will undoubtedly become standard practice in the Navy, possessing as they do several advantages over diesel sets, to which they are preferred above 350 kW. Mr. Pope then gave details of a 1,000-kW. base-load generator set and of a 500-kW. set.

On merchant marine applications, Mr. Pope remarked that engines for this purpose operate their whole life at full power, and, due to the cost of running, only one experimental set has so far been built. He gave figures, however, to prove that maintenance costs are much lower than those for diesel engines, and possibly than those of steam turbines. There is, he said, a certain amount of interest in emergency gas turbine generator sets for the merchant marine. One such machine has been developed; it was first run only 21 months after the initiation of the project, and was delivered after only 26 months.

"Air Development" was the theme of an address by Dr. A. W. Morley, head of Forward Projects Investigations Department, Messrs. D. Napier and Sons, Ltd. Dr. Morley traced the development of the gas turbine engine, dating from Dr. A. A. Griffiths (1926), who applied Prof. Frankel's theory of circulation, to the turbo-prop and jet engines which are known to-day. The piston-engine transport, he said, belongs to the past, and he showed a short film of the conversion of the piston-engine transport to the turbo-prop transport (Convair 340). The reasons for the conversion became evident as the lecture developed; namely, it provided a saving of weight and an increase of power, so that the cruising speed went up as well as the pay-load. This conversion utilized the Eland turbo-prop engine, and Dr. Morley justified the title of his lecture by describing in detail the principles and development of the above engine, including the control system, fuel metering system and torque meter. He also dealt with some of its safety aspects, detailing the maximum torquemeter, and overspeed governor, stressing the fact that the ideal design is such that if one part fails something else comes into play.

Dr. Morley then showed how the introduction of new conceptions brings about new machines, as for example in the Fairey Rotodyne (rotor, 90 ft. diameter), Rolls-Royce "Flying Bedstead" and in helicopter development.

Applications to the motor vehicle were dealt with by Dr. J. H. Weaving, chief research engineer, Austin Motor Co., who described the main steps in development, with slides showing the calculations and results represented in graphical form.

The importance of the heat exchanger was emphasized, and it was shown that there is no point in having high compression ratios if a heat exchanger is used. Dr. Weaving compared the efficiencies of the gas turbine with heat exchanger, petrol and diesel engines at full load; it is possible to achieve efficiencies with gas turbines comparable with the diesel engine if a thermal ratio of 0·9 is used, and comparable with the petrol engine if a thermal ratio of 0·7 is used.

Dr. Weaving stated that research is continuing on rigs to improve the efficiency of individual components. A centrifugal compressor has been on test, and axial compressors of single, two and three stages have been tried. A two-stage compressor giving ratios of 4 to 1 and 6 to 1 without overstressing has been used, and a three-stage compressor is now in service. Research into the design of burner and combustion chamber is being carried out by J. Lucas and Co., Ltd.

Dr. Weaving foreshadowed great developments in the regenerative types of heat exchangers, and concluded his address with illustrations of the result of researches in Great Britain, the United States and on the Continent. The installation of the Austin turbine in the "Princess" saloon was shown, also the *G.T.* 302 "Whirlfire" and its novel installation with twin-disk regenerative heat-exchanger as fitted in the General Motors "Firebird".

SUMMER SCHOOL IN PHYSICS IN THE UNIVERSITY OF MEXICO

LAST summer the University of Mexico held, for the first time, a summer school in physics. The subject on this occasion was theoretical nuclear physics, and the course extended from July 9 until the end of August. The twenty-eight members of the school were mostly graduate students or senior staff in theoretical physics, but also included some experimental physicists. Apart from members of the University of Mexico there were visitors from the Argentine (2), Brazil (3), Cuba (1), Britain (1), France (2), Germany (1), India (1) and the United States (9).

Unesco provided for the travelling expenses of some of the members, others had grants from their own national institutions, and in addition a good deal of local expenditure was borne by the University of Mexico.

The meetings, which were conducted in English, were held in the Physics Department of the University (director, Prof. C. Graef Fernandez) and the programme was designed and arranged by Dr. M. Moshinsky, professor of theoretical physics.

The idea of such a summer school bears some relation (and no doubt has received some inspiration) from the successful summer schools that have become regular institutions in Les Houches (France) and Varenna (Italy); but the Mexican Summer School differed from these older institutions by being rather more specialized. The five lecture courses provided all dealt with parts of nuclear theory; their subjects were: collective motions in nuclei (M. Moshinsky); theory of nuclear reactions (R. G. Thomas); electromagnetic reactions with nuclei (J. S. Levinger); the nuclear shell model (B. Stech); and nuclear forces (R. E. Peierls). Thus they covered specialized and well-defined sections of the subject, and with about twenty-four lectures in each course it was possible to present each topic in fair detail. The lectures were given on three mornings and two afternoons each week. In addition, there was a weekly seminar in which the topics ranged rather more widely, and by request of the members of the School a short series of lectures by Prof. Graef Fernandez on general relativity.

One of the obvious functions of such a course was to give some inspiration and encouragement to the young, but growing, group of theoretical research workers at the University of Mexico, and one had the impression that the members of this group appreciated the opportunity of taking part in a live discussion of modern topics from a variety of points of view. They took part in the lectures and discussions with great enthusiasm, in spite of the language difficulty, which must have demanded of some of them as great or greater effort than the technical difficulties of the subject. The meetings also met with an enthusiastic response from the experimentalists associated with the new nuclear physics laboratory, and both in seminars and outside the lecture rooms there were many occasions when one heard of the fine work done on the Van de Graaff set of the laboratory, and discussed the relations of these results with the theoretical principles that were the main subject of the course.

For the foreign members of the Summer School it was a most stimulating experience to be in Mexico, both because it is always interesting to become acquainted with a new and vigorous research school, and also because they had the chance to see around them so much of beauty and interest. The new University City of Mexico is world-famous for the breath-taking beauty of its buildings and its setting, and there was time enough to see this as a particular example of the achievements of Mexican architecture, which is without comparison in its imaginative use of form and colour, and in the unique way in which it exploits modern building techniques and modern trends, while it remains firmly based on old traditions in art and an impressive sense of continuity of æsthetic values.

For the foreign members there was indeed so much to see outside the Science Institute, and outside Mexico City, that it is a tribute to the programme of the Summer School and to the sense of duty of its members that sight-seeing trips and archæological excursions were normally confined to week-ends or postponed until after the end of the course.

In principle, one might argue that summer schools should not be held in places so attractive as Mexico, and which offer so many alternative interests, or that they should not be held at the sponsoring University, where the local staff have their normal business to attend to. But in this case there was no sign that either of these factors was allowed to divert attention from the activities of the School.

A similar Summer School for 1957 is now under discussion and the subject is likely to be experimental nuclear physics. If the University of Mexico, and the members of the physics staff in particular, are willing to continue to carry the burden involved in the organization of a summer school, and of the generous and friendly hospitality which was provided, the School will undoubtedly establish itself as an important feature in modern physics, which can provide another forum for serious discussion and a focus for the interests of physicists in Latin America.

R. E. Peierls

MYXOMATOSIS IN AUSTRALIA

On September 18 the Commonwealth Scientific and Industrial Research Organization of Australia held a conference in Melbourne to plan the country's myxomatosis campaign for the season.

The conference included representatives of the Organization, the State Departments of Agriculture and of Lands, the Commonwealth Department of Commerce and Agriculture, the Graziers' Federal Council, the Australian Wool and Meat Producers' Federation, the Australian Primary Producers' Union, Commonwealth Serum Laboratories, the Walter and Eliza Hall Institute for Medical Research, and the Australian National University. Sir Ian Clunies Ross was chairman.

Reports from all the Australian States indicated that rabbit populations are extremely low. Myxomatosis has been largely responsible for the reduction in rabbit numbers, but other factors have also contributed; the widespread and organized use of the poison '1080' has been particularly important in Tasmania and Western Australia. Climatic conditions, too, and especially very heavy rainfall, have adversely affected rabbit breeding.

In Tasmania poisoning with '1080' has been most successful. Rabbit numbers have been reduced to an extent which compares favourably with results achieved by myxomatosis in the eastern States.

Prof. F. Fenner, of the Australian National University, reported on his examination of more than 150 strains of myxomatosis virus, including strains from Europe and America.

In Australia, strains of the virus with reduced virulence appeared in the field soon after the initial release of myxomatosis in 1950. These less-virulent strains have become dominant.

In Europe the less-virulent strains did not appear as rapidly but they are now the dominant strains there also.

The conference recommended that further large-scale inoculations with the standard (high-virulence) strain of the virus should be carried out during the coming season to prolong the period of effective use of myxomatosis by allowing fewer rabbits to survive and breed.

If existing low-virulent field strains are allowed to develop without some competition from the standard strain of the disease there will be a much bigger reservoir of survivors to provide genetically resistant progeny.

A high incidence of myxomatosis in the coming spring and summer is predicted. To take maximum advantage of these favourable conditions, a campaign for the general release of the standard (high virulence) strain of the virus has just begun.

Experiments aimed at introducing the 'French' strain of the virus indicated that it did not survive in competition with the existing dominant field strain of low virulence. A warning was given against further introduction of the 'French' strain. It appears that this strain has given rise to much less virulent forms of the virus.

Experiments undertaken by Dr. I. D. Marshall, of the Australian National University, and Dr. W. R. Sobey, of the C.S.I.R.O. Animal Genetics Section, have confirmed that rabbits can inherit some degree of resistance to myxomatosis. Observations in the field have indicated that rabbits are, in fact, inheriting resistance to the disease, but further investigations will be necessary before the degree of this inheritance can be assessed.

The conference was told that it was believed that the European rabbit flea was a major factor in the spread of myxomatosis in the United Kingdom. The Australian Agricultural Council agreed at its meeting in July 1956 to a recommendation that the European rabbit flea be used for myxomatosis experiments in Australia. The conference agreed that such experiments would be valuable, subject to tests to confirm that the flea is harmless to Australian fauna.

The conference urged all landholders to use poison '1080' and all other effective methods after the current myxomatosis season ends. Advantage should be taken of low rabbit numbers to kill off all survivors. The aim must be to eradicate the rabbit from Australia.

DUTCH – NORWEGIAN JOINT ESTABLISHMENT FOR NUCLEAR ENERGY RESEARCH

REPORT FOR 1954–55

THE fourth annual report of the Dutch–Norwegian Joint Establishment for Nuclear Energy Research (J.E.N.E.R.) covers the period from July 1, 1954, to June 30, 1955*, and reports that at Kjeller the natural-uranium heavy-water research reactor, JEEP, has completed its fourth year of operation, yielding 50 MW.-days of heat during the year. A great variety of research work has been done, both in connexion with the design of reactors and of a more fundamental nature, but the principal task of the Establishment is research in the field of nuclear power.

The original design for a pressurized heavy-water reactor, using natural uranium as fuel and heavy water as moderator and coolant, as a power demonstration reactor has been shelved, and instead work has been concentrated on a boiling heavy-water reactor running on slightly enriched uranium and delivering 10 MW. of heat. The Norwegian organization, Institut for Atomenergi (I.F.A.), which together with the Dutch organization, Stichting voor Fundamenteel Onderzoek der Materie (F.O.M.), operates the Joint Establishment, has proposed to the Norwegian Government to build this reactor at Halden, in Norway, 100 km. south of Oslo. The site is on the premises of a paper-pulp plant, Saugbrugsforeiningen, which is interested in the future possibilities of supplying process steam by nuclear reactors, the area being far away from reserves of hydro-electric power. The firm will buy the steam generated in the experiment and will support the project in general. The reactor, except for the control room, will be entirely underground in an artificial cave in the mountainside.

Sales of radioisotopes produced in JEEP increased by 85 per cent more than the previous year. 579 shipments were made, and an additional 262 irradiations were carried out for use within the Establishment. Some radioisotopes, such as labelled compounds and isotopes requiring a high neutron flux which are not easily produced at Kjeller, were imported mainly from the United Kingdom Atomic Energy Authority. The Isotope Department continued its radioisotope service for industry, and a number of new technical applications have been carried out, some of which are briefly described in the annual report.

The neutron diffractometer described in the report for 1953–54 has been improved by the addition of a neutron monitor so that it now gives the number of neutrons scattered by a crystal in a certain direction for a given number of neutrons incident from the reactor, instead of for a given length of time. The angular resolution has also been improved, and a second 'two circle' instrument especially designed for studies of single crystals has been recently put into use. Most of the research work on crystal structures, using neutrons, has been concerned with the determination of 'light' atoms in the presence of 'heavy' atoms, and the substances investigated include CuH, Al_2Th and $Ca(H_2PO_2)_2$. The fission process, the basic process underlying the operation of reactors, has been the subject of experimental and theoretical studies during the year under review, and the angular correlation of fission products, the high-energy gamma radiation from fission fragments and the hazards which might arise from the continuing heat generation from fission products in the event of an accident to a pressurized boiling-water reactor system are some of the topics discussed in the report. A large liquid-scintillation fast-neutron detector, consisting of an aluminium tank, 30 cm. diameter and 30 cm. high, containing an organic scintillator into which cadmium or boron is introduced and viewed by four photomultipliers with 5-in. diameter photocathodes, and a time-of-flight spectrometer have been constructed for studies of fast neutrons.

Work in the Chemistry and Metallurgy Departments has continued on the study of plutonium chemistry and the reprocessing of spent fuel rods, the nuclear properties of uranium oxide fuel rods and full-scale corrosion tests on fuel elements under dynamic conditions. The Health Physics Department has kept constant control of radiation hazards; of the 111 individuals exposed to radiation, not one received a radiation dose greater than half the permissible working dose recommended by the International Commission on Radiological Protection. Five reports and two publications of the Establishment were issued during the year. 300 books, 25 periodicals and 8,500 reports were added to the library, including a technical library consisting of about 6,500 reports (4,900 on microcards), twenty-eight bound volumes of the U.S. Atomic Energy Commission's "National Nuclear Energy Series", a complete set of *Nuclear Science Abstracts* and other material presented by the Commission.

The final sections of the report deal with the accounts of the Establishment for the period under review; the personnel in the various departments; and the various scientific meetings and conferences attended by members of the staff of the Establishment.

* Fourth Annual Report, July 1954–June 1955, of the Dutch–Norwegian Joint Establishment for Nuclear Energy Research. Pp. iii+34. (Kjeller, near Lillestrøm: J.E.N.E.R., 1956.)

MECHANISM OF INSECT FLIGHT

FLIGHT by means of flapping wings demands a higher rate of energy consumption than any other known activity in the animal kingdom. But in no single bird, or bat, or insect has the aerodynamics of the process been closely analysed. Indeed, some authors have claimed that the observed movements of insects would not permit flight in accordance wit ordinary aerodynamic principles. This subject is now being studied with all the care it deserves by T Weis-Fogh and M. Jensen, and their first four papers have been published under the general title o "Biology and Physics of Locust Flight" (*Phil. Trans Roy. Soc.*, B, 239, 415; 1956). Dr. Weis-Fogh is a entomologist and physiologist (a student of the lat August Krogh, who took an active part in the earl stages of the work); Dr. Jensen is an engineer wit a special knowledge of the aerodynamics of aircraft Two of the papers are under joint authorship, an the other two by each author alone.

From a critical review of the available informatio the authors conclude that natural flight is almos certainly based on conventional aerodynamic principles, even in such small insects as mosquitoes. Th energy account of a wing stroke comprises at leas three independent terms: an aerodynamic term du to the wind forces on the wings, an inertial term due to acceleration of the wing mass, and an elastic term caused by the elastic deformations of the thorax. In addition, there may be some extra-muscular damping within the thorax.

In order to analyse how the various wing-stroke parameters are related to the *lift* and the forward *thrust*, the locust was suspended from a complicated balance and flew against a uniform wind the speed of which was automatically adjusted to the point where the thrust was equal to the drag of the body, thus indicating the flying speed. This speed averaged 3·5 m./sec., but might be as much as 4·5–5·0 m./sec. during the first minutes of flight. The power necessary to overcome the drag of the body was only 1–3 per cent of the total metabolic rate; and changes in the inclination of the body up to 20° had no effect at all on the lift, in striking contrast to the effect of pitch on an aircraft. Most of the parameters of the wing stroke are remarkably constant, such as the stroke angles, the stroke plane angles, the middle position of the wings and the time course of the angular movement. Even the stroke frequency showed a maximum increase of 8 per cent during the most active lift. It is therefore concluded that, by analogy with a variable-pitch propeller, the great variations in lift must be caused by differences in *wing twisting*. It is rather remarkable that over the whole range of temperature (25–35° C.) at which flight occurs, the standard wing stroke is completely independent of temperature.

In a detailed analysis of the aerodynamics of locust flight it was found that the calculated vertical lift force, when averaged over an entire wing stroke, equalled the average reduction in body-weight as measured directly on the flight balance. Likewise, the average thrust of the wings as calculated, corresponded with the measured drag of the body. The hind-wings are responsible for about 70 per cent of the total lift and thrust, about 80 per cent of the lift being produced during the down-stroke.

As already noted, the wing stroke of locusts is extremely constant and independent of external conditions. The question arises whether the rhythm is imposed by the central nervous system or peripherally. In the fourth paper of the series, Weis-Fogh discusses some of the sensory mechanisms concerned in locust flight. As is well known, flight can be initiated by the 'tarsal reflex'—sudden removal of contact with the legs; but this causes only about five seconds of flight, or about a hundred wing strokes. Sustained flight is dependent upon the blowing of air over the wind-sensitive hairs on the head. The direction of the air current is immaterial, and, since static bending has no effect, the adequate stimulus is probably minute vibrations of the hairs. A new receptor system is also involved in the maintenance of flight. The adequate stimulus is the rhythmically changing wind-pressure on the wings. The receptors perhaps reside in the wing-hinge, but they have not yet been identified. Finally, in addition to the wing-stroke movements being strikingly constant, there is a very accurate control of the lift; this presupposes a system of lift-sensitive receptors (probably campaniform sensilla at the wing-hinge) which control reflexly the wing-twisting angle.

This important work is still incomplete; six further sections are in preparation.

ENZYMIC AND CHEMICAL SYNTHESIS OF THE ALPHA-1 : 2-GLUCOSIDIC LINKAGE

Enzymic Synthesis

WHEN the dextran-producing organism *Betacoccus arabinosaceous* is grown on a medium containing sucrose and an appropriate second sugar (to serve as an acceptor of transferred glucose units) oligosaccharides are produced in appreciable quantities[1]. A particularly interesting example is the formation of the 'branched' trisaccharide, O-β-D-galactopyranosyl-(1→4)-O-[α-D-glucopyranosyl-(1→2)]-D-glucopyranose, from a mixture of sucrose and lactose[1]. It is now shown that, as was envisaged earlier[1], cellobiose behaves in an analogous fashion to lactose and gives rise to the 'branched' trisaccharide, O-β-D-glucopyranosyl-(1→4)-O-[α-D-glucopyranosyl-(1→2)]-D-glucopyranose. The preliminary chromatographic evidence upon which this work is based was obtained by our former colleague, Dr. R. W. Bailey.

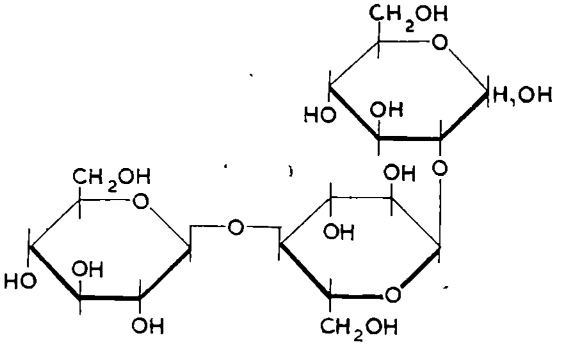
The new trisaccharide was isolated by the charcoal column method[2] from a culture of *Betacoccus arabinosaceous* (Birmingham strain), which had been grown on a medium containing yeast extract, inorganic salts, sucrose (10 per cent) and cellobiose (30 per cent).

The molecular size was confirmed by oxidation with hypoiodite[3] and by ionophoresis of the benzylamine derivative in formic acid[4]. Acidic hydrolysis gave glucose as the only product detectable by filter-paper chromatography and by ionophoresis in borate (*p*H 10)[5]; partial hydrolysis yielded components corresponding to glucose, cellobiose and a second disaccharide (*Y*). The reducing power of the trisaccharide towards the Shaffer–Hartmann copper reagent[6] was only about 2·5 per cent of that of glucose, a discrepancy which is shown generally by 2-O-substituted glucoses[1]. Moreover, the trisaccharide and disaccharide *Y*, in common with the analogous trisaccharide derived from lactose, were not developed by alkaline triphenyltetrazolium chloride, which detects all reducing glucosaccharides except those with a 2-O-substituent[7]. Further evidence that the reducing unit of the trisaccharide was linked through position 2 was obtained when treatment with phenylhydrazine acetate yielded a mixture of two osazones, similar to cellobiosazone and glucosazone on microscopic examination.

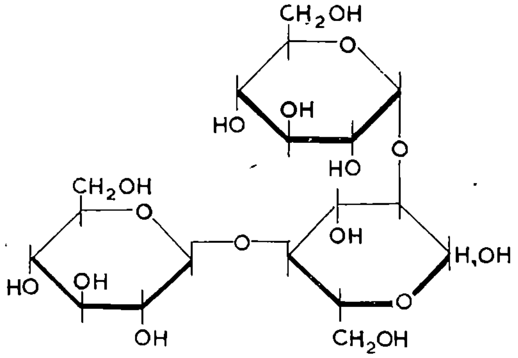
That one of the glycosidic linkages in the trisaccharide was α and the other β was shown (*a*) by its $[\alpha]_D$ value (+93° equil.; conc. 1·00 in water) and also that of the alcohol derived from it (+89° equil.; conc. 1·00 in water), (*b*) by its infra-red absorption spectrum, which displayed a peak at 840 cm.$^{-1}$ (α-linkage) in addition to those given by cellobiose[8], and (*c*) by its conversion to glucose and disaccharide *Y* with almond β-glycosidase.

This enzymic hydrolysis proceeded much more slowly than with β-linked disaccharides. The products were separated on a charcoal–'Celite' column and a sample of disaccharide *Y* was thus obtained. A disaccharide (*X*) was prepared from the lactose-derived trisaccharide in a similar manner. The earlier conclusion[1] that *X* was 2-O-α-D-glucopyranosyl-D-glucose and the above indications that *Y* was identical with it were confirmed (*a*) by paper chromatography and ionophoresis in borate, *p*H 10 [M_G 0·32 (eliminates 1 : 3- and 1 : 6-linkages)[5]], direct comparison eliminated maltose as a possibility ; (*b*) by molecular weight determinations using ionophoresis in formic acid and oxidation with hypoiodite ; (*c*) by their low reducing power (about 12 per cent of that of glucose) towards the Shaffer–Hartmann reagent (*cf.* sophorose[6]) ; (*d*) by 96 per cent conversions into glucose with acid ; (*e*) by their high $[\alpha]_D$ values (+133° equil. ; conc. 0·94 in water) ; (*f*) by their infra-red absorption spectra, which displayed peaks at 840 cm.$^{-1}$ (α-linkages) but not at 894 cm.$^{-1}$ (β-linkages[8]) ; (*g*) by their resistance to almond β-glycosidase and (*h*) by the similarity of their stains (aniline hydrogen phthalate spray) with that of sophorose. Direct comparisons with a sample kindly supplied by Dr. Whelan (see following communication) were made by infra-red analysis, paper chromatography, ionophoresis of the benzylamine derivatives and ionophoresis in borate (*p*H 10) and identical results were obtained. Thus *X* and *Y* were both 2-O-α-D-glucopyranosyl-D-glucose (kojibiose[10]).

Two possible structures remained for the cellobiose-derived trisaccharide ; these are shown in (I) and (II). The former was considered unlikely when the method of synthesis was taken into consideration and was eliminated also when the sugar consumed 3·90 mol. of periodate with the production of 1·75 mol. of formic acid and no formaldehyde (theoretical value : II, 4, 2, 0) and when its alcohol consumed 5·02 mol. of periodate, giving 1·92 mol. of formic acid and 0·85 mol. of formaldehyde (theoretical values : I, 6, 3, 1 and II, 5, 2, 1). Thus the trisaccharide was O-β-D-glucopyranosyl-(1→4)-O-[α-D-glucopyranosyl-(1→2)]-D-glucopyranose. It is possible that the trisaccharide which was isolated by Buston and Khan[11], following treatment of cellobiose with an extract from *Ch. globosum*, is analogous to our trisaccharide ; indeed, these authors noted certain similarities between their trisaccharide and sophorose.



(I)



(II)

We thank Dr. R. W. Bailey for valuable assistance in the preliminary investigations of the trisaccharide.

Chemical Synthesis

The formation of 1 : 2-linked polymers of α-D-glucopyranose has been examined as part of our investigations of the chemical synthesis of sugar polymers[1]. The problem had an added interest since the occurrence of the α-1 : 2-glucosidic linkage in Nature has only been recognized very recently and the linkage has not previously been synthesized by chemical methods. The previous communication reports the enzymic synthesis of this linkage, and Shibasaki[2] has described the presence of a diglucose (kojibiose) believed to contain the α-1 : 2-linkage, in a mixture of disaccharides synthesized from glucose by *Schizosaccharomyces pombe*.

The method of synthesis was suggested by the observation[3] that α-glucosides are formed when 1 : 2-anhydro-3 : 4 : 6-tri-O-acetyl-α-D-glucopyranose (Brigl's anhydride[4]) is heated with a suitable molecule containing a hydroxyl receptor group. In this way maltose, sucrose and αα-trehalose were synthesized[3]. It occurred to us that heating the Brigl anhydride alone might cause it to polymerize, with the formation of a polymer of α-1 : 2-linked glucose units. When the anhydride (m.p. 60°) was heated at the temperature of boiling butan-1-ol (b.p. 118°) the initially thin colourless liquid began to darken and thicken during 2–3 days and after a week had set to a hard syrup. Paper chromatographic fractionation of the deacetylated material revealed glucose and a series of benzidine-reducing oligosaccharides, which had the linear R_M value/DP relationship characteristic of a polymer homologous series[5]. The disaccharide component was isolated. Although it migrated as a single zone on a paper chromatogram it proved to be a mixture of three substances. This was revealed when, after treatment with cold phenylhydrazine acetate, paper chromatography resolved the substance into three zones. Two were coloured yellow (phenylhydrazones); the third, occupying the original position, was due to a non-reducing sugar, identified as αα-trehalose. The two coloured zones were separated and reconverted into the free sugars. The sugar from the faster-moving zone may be a 2 : 2-linked disaccharide; the other has been identified as O-α-D-glucopyranosyl-(1→2)-D-glucose.

The evidence of identification is as follows: (*a*) Acid hydrolysis gave rise to glucose as the only product (paper chromatography). (*b*) Hypoiodite oxidation indicated a disaccharide and confirmed the presence of a reducing group. (*c*) The $[\alpha]_D$ value of +140° (conc. 0·06) suggested the presence of an α-linkage, an inference confirmed by the infra-red absorption peak at 840 cm.$^{-1}$ (α-linkages), but not at 894 cm.$^{-1}$ (β-linkages) (see previous communication). (*d*) The M_G value of 0·32 in borate buffer, *p*H 8·7, shows that the linkage cannot be 1 : 3 or 1 : 6 and the R_F value in butan-1-ol–pyridine–water (3 : 1 : 1) was different from that of maltose (α-1 : 4-link) as well as from nigerose (α-1 : 3) and isomaltose (α-1 : 6). (*e*) Unlike the three last-named disaccharides the new sugar does not react on paper with alkaline triphenyltetrazolium chloride, a property suggestive of substitution at C–2 of the reducing glucose unit[6]. (*f*) Further indication of C–2 substitution is the copper-reducing value of less than 2 per cent as glucose (Somogyi reagent[7]). Sophorose (O-β-D-glucopyranosyl-(1→2)-D-glucose) has the same reducing power. Nigerose, maltose and isomaltose have approximately 50 per cent of the copper-reducing power of glucose. (*g*) Oxidation of the borohydride-reduced disaccharide with a limited amount of sodium metaperiodate (5 molecular proportions) yielded 1·36 mol. prop. of formaldehyde. Treated in the same way, reduced maltose gave 2·20 mol. prop. of formaldehyde.

All these properties are consistent with the assignment of the structure O-α-D-glucopyranosyl-(1→2)-D-glucose to the synthetic disaccharide and confirm the expected manner of polymerization of the Brigl anhydride. The fact that other disaccharides were formed, and, indeed, that disaccharides were formed at all is explicable on the basis of a chain-terminating reaction being caused by traces of moisture. Water should react with the anhydride to form 3 : 4 : 6-tri-O-acetyl-α-D-glucopyranose, which could in turn react with anhydride to yield either αα-trehalose or the α-1 : 2-disaccharide.

As mentioned earlier, the name 'kojibiose' has been applied by Shibasaki and co-workers[2] to a new glucose disaccharide, believed to contain the α-1 : 2-linkage. We are informed by Drs. Shibasaki and Matsuda that they have confirmed its supposed identity. We therefore propose to apply the name kojibiose to the α-1 2-linked diglucose.

This work was begun at the University College of North Wales, Bangor, and our thanks are due to Prof. Stanley Peat for his encouragement. We also thank Mr. P. M. Grant for the infra-red data, and Dr. S. Hestrin for information about the triphenyltetrazolium chloride spray.

CYTOPLASMIC CHANGES ASSOCIATED WITH ADAPTATION AND DIFFERENTIATION

By PAULINE G. BRIAULT

Agricultural Research Council Unit of Biometrical Genetics, Department of Genetics, University of Birmingham

RECENT investigations have shown that cytoplasmic changes accompany the growth, differentiation and ageing of homocaryon colonies of a number of species of the *Penicillia* and *Aspergilli*. Variation in the behaviour of colonies derived from single asexual spores of a homocaryon colony has been attributed to the unequal distribution of cytoplasmic elements at spore formation[1,2]. This variation among spores has been used as the basis of selection experiments, by which marked differences in phenotypic behaviour, of purely cytoplasmic origin, have been established.

Induced cytoplasmic changes, obtained by alteration of the medium on which the fungus is grown, have now been investigated in *Aspergillus glaucus*, the cytoplasmic nature of the changes being confirmed by the methods of Jinks[1,2].

Two cytoplasmic changes have been investigated: first, the change induced by transfer from normal medium to medium containing mercuric chloride, and secondly, that induced by transfer to medium in which galactose or xylose had been substituted for the sucrose normally used.

Mass hyphal transfers from normal medium grew on medium containing up to 9 μgm./ml. of mercuric chloride, with no reduction in vigour and at a steady rate, following lag periods of up to fourteen days (during which growth did not occur or was negligible).

Asexual spore transfers from normal medium showed that some of the spores, but only a small proportion, were also capable of growth on mercuric chloride medium, after varying lag periods. No spores were capable of growth on concentrations exceeding 3 μgm. mercuric chloride/ml. Spores of a uniform age from any one colony were found to be markedly heterogeneous for the level of poison on which they were capable of growing.

Hyphal transfers from adapted colonies (that is, colonies growing on the mercuric chloride medium) to mercuric chloride medium grew with no significant lag.

The behaviour of the asexual spores from adapted colonies on the mercuric chloride medium was, on the other hand, very little different from that of the spores from an unadapted colony. Spores from adapted colonies showed the same heterogeneity in concentration of poison tolerated and in lag period of survivors on any one concentration as did spores from unadapted colonies. As with spores from unadapted colonies, concentrations greater than 3 μgm. mercuric chloride/ml. were completely toxic.

Table 1 gives the distribution of toleration of various levels of mercuric chloride in a sample of asexual spores from a colony on 5 μgm./ml. mercuric chloride. The variation in age among the spores of the sample was less than 48 hr. The cytoplasmic heterogeneity is thus almost entirely due to unequal distribution of cytoplasmic elements at spore formation, the effect of mycelial and spore ageing being very small.

Table 1

Level of mercuric chloride	Percentage of spores in random sample
0·0–0·5 μgm./ml.	3·4
0·5–1·0 ,,	1·8
1·0–2 0 ,,	83·6
2·0–3·0 ,,	9·5
3·0 ,,	1·7

Only on concentrations just below toxic, that is, about 3 μgm./ml., was there a significant difference in the behaviour of spores from adapted and unadapted colonies on the mercuric chloride medium. On these sub-toxic concentrations, spores from adapted colonies of most lines gave a higher percentage survival, and a shorter mean lag period of the survivors, than spores from unadapted colonies. This difference is illustrated in Table 2.

Table 2

Homocaryon line	Percentage survival of spores From unadapted colony	Percentage survival of spores From adapted colony	Difference in mean lag period
1_1	4 4	7·8	22 hr.
1_2	2 2	20 2	150 hr.
1_3	0·0	0·0	0 hr
2	4·6	25·1	42 hr.

When the behaviour of mass hyphal transfers on the galactose and xylose media was investigated, growth was found to start after a lag period of a few days, during which little or no growth occurred.

Samples of asexual spores of uniform age, from different homocaryons raised on sucrose, when plated on to sucrose, xylose and galactose, showed significant variation in ability to grow, both between homocaryons and between sugars (Table 3). The variation on xylose and on galactose was about three times that on sucrose. Similarly, the variation in the lag period on the new sugars was significantly greater than on the sucrose medium.

Table 4 compares the behaviour of asexual spores taken from single colonies grown on the three sugar media when placed on the same and different media. For each colony the highest survival rate of the spores is taken as 100, the shortest lag period as 0 hr.

Table 3. THE RELATIVE PROPORTIONS OF ASEXUAL SPORES FROM SINGLE COLONIES OF TWO LINES ON SUCROSE MEDIUM CAPABLE OF GROWTH ON SUCROSE, GALACTOSE AND XYLOSE

(Highest survival-rate for each line taken as 100, lowest mean lag period as 0)

Line	Medium	Percentage of asexual spores giving a colony	Mean lag period
1_3	Sucrose	100·0	0 hr.
	Galactose	92 4	44 hr.
	Xylose	81 8	48 hr.
1_4	Sucrose	100·0	0 hr.
	Galactose	100 0	34 hr.
	Xylose	87 5	24 hr.

From Table 4 it can be seen that, for any one sugar, a greater percentage survival, smaller mean lag period, and less variation in lag period, is obtained on transfer to the medium to which the parent colony is adapted than to a different sugar.

Table 4

Medium to which mycelium adapted	Medium on which spores plated					
	Sucrose		Galactose		Xylose	
	Survival	Lag period	Survival	Lag period	Survival	Lag period
Sucrose	100	0 hr.	100	34 hr.	87·5	24 hr.
Galactose	52·9	0 hr.	100	0 hr.	23·5	47 hr.
Xylose	54·9	3 hr.	36·8	16 hr.	100	0 hr.

Jinks has shown that it is possible to select for cytoplasmic differences among the cytoplasmically heterogeneous colonies obtained from large numbers of single asexual spores[2]. Selection for any one character, for example, growth-rate, or perithecial density, was invariably accompanied by a correlated change in all the other characters investigated. It has now been found that selection for these characters is accompanied also by a change in the behaviour of the asexual spores from the selected colonies on the mercuric chloride medium. Cytoplasmic variants of various lines, selected for high growth rate, were found to give survival rates varying between 14 and 30 per cent on concentrations of mercuric chloride just below 3 μgm./ml. compared with a survival rate of 2–3 per cent for spores from unselected colonies. The change in survival rates of the spores brought about by selection in the complete absence of mercuric chloride is equal to, if not greater than, that brought about by prior adaptation of the parent colony to the mercuric chloride medium.

It is evident from these observations that the asexual spores of a colony show heterogeneity, of cytoplasmic origin, in their ability to grow on the media tested. Furthermore, there is a difference in the behaviour of hyphal and asexual spore transfers to the adaptive medium, hyphal transfers in general being more successful. This is most marked in the case of the mercuric chloride adaptations, where, even after adaptation of the parent colony, only a small proportion of the spores are capable of growth on the mercuric chloride medium.

The observations made here are in keeping with those made earlier on cytoplasmic differences affecting growth rate, perithecial density and other characters, in which asexual spores of a single homocaryon colony showed marked cytoplasmic heterogeneity, and colonies derived from asexual spore transfers and hyphal transfers differed in mean cytoplasmic content.

I am indebted to Dr. J. L. Jinks and Mr. L. G. Wigan for guidance and criticism.

AGE AND OXIDATIVE PHOSPHORYLATION IN RAT LIVER AND BRAIN

By EUGENE C. WEINBACH* and JOEL GARBUS†

U.S. Department of Health, Education and Welfare, Public Health Service, National Institutes of Health,
Bethesda, Maryland

THE scanty literature concerned with the ageing process in relation to enzymatic activity does not contain any systematic study of oxidative phosphorylation. Such a study is of considerable importance, because oxidative phosphorylation is generally regarded as the primary metabolic process in aerobic cells for the generation of adenosine triphosphate[1]. Recent experiments in the Laboratory of Tropical Diseases demonstrated an uncoupling of oxidative phosphorylation in particulate preparations of albumen gland correlated with decreased fertility in aged snails[2]. These findings suggested similar research with mammalian tissues. Concurrent studies in the Section on Ageing had shown no decline in the respiration of fortified rat brain homogenates associated with age[3], and it became of interest to study oxidative phosphorylation in these preparations. The availability of a colony of inbred rats especially maintained to study ageing facilitated a joint investigation in the two laboratories.

Sprague–Dawley rats, grossly free from disease, were killed by decapitation; the brain and liver were removed simultaneously, and immediately chilled in cold 0·25 *M* sucrose.

Mitochondria were isolated from liver tissues in 0·25 *M* sucrose essentially by the procedure of Schneider[4]. The mitochondria were washed once; each ml. of the final suspension represented 0·5 gm. of original tissue. The supernatant fluid which remained after the mitochondrial sedimentation was centrifuged at 20,000 *g* for 30 min. at 0° to obtain a clear, soluble fraction for the glycolytic experiments. Oxidative phosphorylation was studied in the liver mitochondria with the use of β-hydroxybutyrate as substrate[5]. The oxidation of this substrate was determined by colorimetric estimation[6] of the acetoacetic acid formed.

It may be seen in Table 1 that the amounts of phosphate esterified and β-hydroxybutyrate oxidized (formation of acetoacetate) were significantly lower —30 per cent—in the mitochondrial preparations of old rats as compared to those obtained from the younger (control) animals. In a few experiments, the preparations from animals only a few days old had a lower activity, while those from animals 8–20 days old displayed a higher activity than the preparations from the control group. On the other hand, in all age-groups, the phosphorus/acetoacetic acid ratios remained essentially the same. Thus, in the case of liver tissue, there was observed no uncoupling of phosphorylation from oxidation but a definite decrease in the level of both activities associated with age. No sex differences were noted. Independent tests revealed that the adenosine triphosphatase activity of freshly prepared mitochondria from the old rats was low and responded to uncoupling agents (latency effect) in the same manner as mitochondria from the control rats. Since all the data in Table 1 were calculated on a nitrogen basis, the reduced level of oxidative phosphorylation found in the older rats cannot be ascribed to the addition of less mitochondrial nitrogen to the reaction flasks. In fact, there was little difference in the amount of nitrogen found (micro-Kjeldahl) in the mitochondrial preparations from the older animals (average value, 1·42 mgm. nitrogen/ml.) as compared with the control preparations (1·45 mgm. nitrogen/ml.).

In contrast to these findings were the observations of glycolytic phosphorylation. As seen in Table 1, there was no decline in the anaerobic uptake of phosphate, nor was the glycolytic activity reduced in liver preparations from the old rats. These findings are analogous to our experience with snail tissue where glycolytic phosphorylation also did not decline with age.

Oxidative phosphorylation was measured in brain homogenates with succinate as substrate[7]. 10 per cent homogenates were prepared in 0·25 *M* sucrose

Table 1. EFFECT OF AGE ON OXIDATIVE AND GLYCOLYTIC PHOSPHORYLATION IN CELL-FREE FRACTIONS OF RAT LIVER*

Oxidative phosphorylation (mitochondria)

Age	No. of exps.	P uptake (μM/mgm. N)	Acetoacetate (AA) formed (μM/mgm. N)	P/AA
3 months (control)	14	16·8 ± 1·42	6·0 ± 0·68	2·8
24–37 months	10	11·8 ± 1·55	4·0 ± 0·70	2·9

All t ratios are significant, $p < 0·001$

Glycolytic phosphorylation (supernatant fraction)

Age	No. of exps.	P uptake (μM/mgm. N)	Lactate formed (μM/mgm. N)
3 months (control)	6	4·2 ± 1·97	4·3 ± 1·16
24–37 months	6	5·0 ± 1·39	5·2 ± 1·20

Table 2. Effect of Age on Oxidative Phosphorylation in Brain Homogenates*

Age	No. of exps.	O_2 uptake (μatoms/mgm. dry wt.)	P uptake (μM/mgm. dry wt.)	P/O
3–8 months (control)	10	0·66 ± 0·06	1·08 ± 0·09	1·64
22–33·5 months	10	0·65 ± 0·10	1·05 ± 0·16	1·61

* Figures are mean values ± one standard deviation.

Each flask contained in a final volume of 3 ml. $1\cdot2 \pm 10^{-2}$ *M* potassium phosphate, *p*H 7·4, 1×10^{-2} *M* sodium succinate, $1\cdot2 \times 10^{-2}$ *M tris*† buffer, *p*H 7·4, 5×10^{-3} *M* magnesium chloride, 2×10^{-3} *M* adenosine triphosphate (Sigma), 5×10^{-4} *M* diphosphopyridine nucleotide, $1\cdot5 \times 10^{-5}$ *M* cytochrome *c*, 2×10^{-2} *M* glucose, 0·5 mgm. hexokinase, 2×10^{-2} *M* potassium fluoride and 1 ml. 10 per cent homogenate. 0·2 ml. 10 per cent potassium hydroxide in centre well. Incubated in air for 30 min. at 30°. For details see ref. 7.

† *Tris* (hydroxymethyl) aminomethane.

and aliquots immediately added to chilled Warburg vessels containing all other components. As seen in Table 2, and in contrast to the liver studies, no decline was found in the oxygen consumption or phosphate uptake in homogenates from the old rats as compared with the controls. However, the lack of decline in oxygen consumption is in accord with previous respiration studies[3]; and in addition, the phosphate findings suggested that the coupled phosphorylation also is not depressed with age in the brain tissue. These results, together with the liver studies, indicate that in neither organ is there a change in the phosphorus/oxygen ratio with age. On the other hand, the lower absolute level of substrate oxidation and of the coupled phosphorylation found with liver, but not with brain, may be a reflexion of differences in tissue susceptibility to senescence.

Although the activity of some enzymes may increase with age[8], a general concept of ageing is one of progressive decline in the metabolic activities of the cell. If the *in vitro* experiments reported here with liver tissue are a valid reflexion of hepatic metabolism *in vivo*, then the decline in the absolute level of oxidative phosphorylation strongly supports this concept. It is of interest that studies with rat liver homogenates[9] did not show any significant correlation between age and oxygen consumption. The possibility exists that in cell-free homogenates, amply supplied with substrate and co-factors, age differences in metabolic behaviour which may be operating *in vivo* are masked to some extent *in vitro*. Perhaps isolated mitochondria represent a more subtle tool, because of their unique morphology and fragility, for investigating the ageing process. The studies with liver suggest the possibility in some tissues of a shift in phosphate metabolism from oxidative to glycolytic exergonic reactions accompanying senescence. Work is in progress to explore this possibility as well as other facets of the relation of ageing to enzymatic activity.

COSMIC-RAY INTENSITY AND GEOMAGNETISM

By Prof. WALTER ELSASSER
University of Utah

and Prof. E. P. NEY and Prof. J. R. WINCKLER
University of Minnesota

In a series of papers, E. and O. Thellier[1] have measured the remnant magnetism of ancient bricks. By comparison of the original magnetic moment of a sample with the moment acquired by heating above the Curie point and cooling in the present Earth's field under proper conditions, they have deduced the magnitude of the total Earth's field in ancient times when the bricks were fired. The results are summarized in Table 1.

Table 1

Source of sample	Date	*H* (gauss)
Caule Sainte-Beuve	1933	0·456
Palais Rihour–Lille	1465	0·56
Gallo-Roman remains	≈ A.D. 200	0·71

During the past two thousand years, the total field intensity in France appears to have dropped 65 per cent. We should like to point out that, if such a decrease has been general over the Earth's surface, the incident flux of cosmic rays and the rate of production of radio carbon must have increased during this period. The change in the carbon-14 inventory may be estimated as follows:

(1) Assume that the rate of production of carbons 14 is proportional to the *particle* flux of cosmic ray over the Earth's surface. This implies that the production per primary does not depend on energy, that is, at higher cosmic-ray energies the energy goes predominantly into mesons rather than an increasing flux of nucleons per primary. In Table 2 we compare the measured total primary flux at each latitude[2] with the neutrons absorbed in a column of the atmosphere 1 cm.^{2} in cross-section at each latitude[3]. The neutron captures per primary particle (column 4) are reasonably constant up to the latitude of the 'knee' (≈ 58°).

Table 2

Geo-magnetic latitude	Primary flux (No./cm.^{2}-sec.-ster.)	Neutron captures/cm.^{2}-sec.	Neutron captures/primary particle	$\left(\frac{Pc}{e}\right)$ min. (gauss-cm.)
0	0·021	0·48	3·6	$5\cdot0 \times 10^7$
20	0·025	0·64	4·0	$3\cdot86 \times 10^7$
28	0·033	0·88	4·3	$3\cdot02 \times 10^7$
41	0·053	1·35	4·1	$1\cdot62 \times 10^7$
51	0·095	1·80	3·0	$0\cdot78 \times 10^7$
58	0·15	2·05	2·2	$0\cdot39 \times 10^7$
90	0·15	2·15	2·3	0

(2) Assume that the primary integral number-rigidity spectrum has the form:

$$N\,(>E) = C\Big/\left(\frac{Pc}{e}\right)^n \quad \infty > \frac{Pc}{e} > \left(\frac{Pc}{e}\right)_0 \tag{1}$$

C is a constant and n is the power law exponent. The integral spectrum is constant for $\left(\frac{Pc}{e}\right) < \left(\frac{Pc}{e}\right)_0$ corresponding to the knee observed in the latitude effect of primaries, and there has the value $C\Big/\left(\frac{Pc}{e}\right)_0$. From the data in columns 2 and 5 of Table 2, we find that $n = 0{\cdot}93$, $C = 4{\cdot}03 \times 10^5$ and $\left(\frac{Pc}{e}\right)_0 = 0{\cdot}39 \times 10^7$ gauss-cm. at $\lambda = 58°$. To facilitate the further computations, we assume $n = 1$.

(3) Assume that the average minimum $\frac{Pc}{e}$ at any latitude is that corresponding to a vertically incident particle. The solid angle available to particles of $\frac{Pc}{e} > \left(\frac{Pc}{e}\right)_{\text{min.}\,(\lambda)}$ is $\Omega = 2\pi$.

The flux over the entire Earth's surface in particles per second, Φ, is then given by:

$$\Phi = \Omega \int_0^{\lambda'} C\Big/\left(\frac{Pc}{e}\right)_{\text{min.}\,(\lambda)} 2\pi\, a^2 \cos\lambda\, d\lambda + \Omega \int_{\lambda'}^{\pi/2} C\Big/\left(\frac{Pc}{e}\right)_0 2\pi\, a^2 \cos\lambda\, d\lambda \tag{2}$$

where λ' is the geomagnetic latitude of the knee.

From geomagnetic theory we know that the critical value of the Størmer variable r_0 for the vertical direction is $r_c = \frac{\cos^2\lambda}{2}$. Since by definition $r_0^2 = a^2\Big/\frac{eM}{Pc}$, where a is radius of the Earth, M is magnetic moment of the Earth, if we set $r_c = r_0$ then,

$$\left(\frac{Pc}{e}\right)_{\text{min.}\,(\lambda)} = \frac{\cos^4\lambda}{4} \cdot \frac{M}{a^2} \tag{3}$$

By substituting (3) in (2) we obtain:

$$\Phi = \frac{A}{M}\left\{\int_0^{\lambda'} \frac{d\lambda}{\cos^3\lambda} + \frac{1}{\cos^4\lambda'}\int_{\lambda'}^{\pi/2} \cos\lambda\, d\lambda\right\} \tag{4}$$

$$A = 8\pi\, a^4\, \Omega\, C$$

$$n = 1$$

The integrals in the brackets are functions of M as the limits contain the cosmic ray 'knee', λ'. At the 'knee' $\cos^4\lambda' \,.\, M =$ constant, from (3). Calculations show that the dependence of Φ on M given by (4) may be well represented by the relation $\Phi = \frac{C_1}{M^{0\cdot 52}}$, and then the rate of production of carbon-14 by

$$P(t) = \frac{C_2}{[M(t)]^{0\cdot 52}} \tag{5}$$

remembering that the magnetic dipole moment is dependent on time. The differential equation for the carbon-14 inventory over the Earth is then:

$$\frac{dI}{dt} = P(t) - \lambda_1 I \tag{6}$$

where λ_1 is the decay constant for[4] carbon-14 $= \frac{0{\cdot}693}{5568}$ years^{-1}.

To carry out the integration of (6) the function $P(t)$ must be known over all past time, whereas the experimental magnetic field data only extend back for two thousand years. Therefore, to estimate the *minimum* effect consistent with these data, we make the following assumption:

$$P(t) = P_0 = \text{const.} \quad t < 0$$

$$P(t) = P_0 \exp(\lambda_2 t) \quad 0 < t < 1933 \text{ years A.D.}$$

The values in Table 1 are well fitted by the exponential if we make $\lambda_2 \frac{1}{7950}$ years^{-1}. Also $P_0 = C_2/M_0^{0\cdot 52}$

The integration of (6) then yields:

$$I = \frac{C_2}{M_0^{0\cdot 52}\,\lambda_1(\lambda_1 + \lambda_2)} \cdot (\lambda_2 \exp(-\lambda_1 t) + \lambda_1 \exp(\lambda_2 t)) \tag{7}$$

We then find that the relative carbon-14 inventory at $t = 0$ and $t = 1933$ is

$$\frac{I\,(1933)}{I\,(0)} = 1{\cdot}018$$

From the radioactive decay equation as given, for example, by Libby (ref. 4, p. 9), we find that an object about 2,000 years old would be dated too old by 240 years. This is scarcely outside the errors in the dating process even for a good sample, and probably would escape detection (see, for example, ref. 4, Fig. 1).

It is clear, however, that if the magnetic field has been decaying for longer periods of time than the two thousand years covered by the Thellier data, much larger discrepancies in carbon-14 dating might arise. If the decay were exponential with the same constant $\lambda_2 = \frac{1}{7950}$ years^{-1} for four thousand years, samples of this age should exhibit a specific carbon-14 activity too low by an amount corresponding to an age 1,000 years too old. This seems to be outside the errors indicated by Libby.

One important consideration is that the Thellier data apply locally in France and may not be representative of the overall dipole field. The secular analysis of Vestine[5], for example, extending over forty years, shows that local rates of change are large enough to produce such variations if they persist sufficiently long. This would require harmonic components in the secular variation with periods longer than a hundred years. However, in past geological history there is good evidence for very large changes in the magnitude of the dipole field and its orientation, including complete reversals[5,6]. Certainly one might anticipate that major changes have occurred in the Earth's magnetism in the period covered by the carbon-14 dates. The considerations brought forward here will have greater significance if knowledge of the ancient magnetism of the Earth could be extended to earlier times.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Attenuation of Host Reaction to Ovarian Homografts

GRAFTS derived from ovarian tissue which has been treated with glycerol and frozen to, and stored at, − 79° C. are endocrinologically active but contain comparatively few oocytes[1]. The oocytes which survive freezing and thawing can mature and undergo ovulation even in subcutaneous grafts[2]; but it is not yet known whether they are capable of normal fertilization and development. An approach to this problem involves orthotopic grafting at the ovarian site of the ovariectomized or sterilized recipient and, ideally, the use of a graft from a genetically distinguishable donor so that the source of any offspring produced is not in doubt. With the animals at present available at this Institute the latter requirement implies interstrain ovarian homografting and has led us to consider possible methods of attenuating or suspending the immunological reaction evoked by such grafts.

Several different procedures have been found to modify host reaction to homografts of various kinds[3]. The most attractive one from the present point of view is based on the observation that the growth of certain homologous grafts is enhanced by the previous intraperitoneal injection of the host with suspension of killed tissue of the same genetic composition as the prospective graft. This effect of such pretreatment, discovered and extensively studied in relation to tumour tissue[4], was not found by Kaliss and Spain[5] to occur with normal tissues; but Billingham, Brent and Medawar[6] have recently reported slight prolongation of survival of skin homografts following the pretreatment of the host with lyophilized tissue from the donor strain.

Two strains of rats, albino and hooded, are available at this Institute. With both of these, intrastrain ovarian homografts take and persist readily, while interstrain homografts are frequently accepted but persist less readily[7]. In particular, ovarian tissue from 'hooded' donors grafted into albino hosts usually ceases to function within a month, and this combination was therefore chosen for work on pretreating the recipients.

Ovaries of the hooded strain were homogenized in Ringer solution, frozen and thawed, once or repeatedly, and the suspension injected intraperitoneally. In an early experiment a suspension equivalent to a total of five pairs of ovaries was given to each albino recipient on days 14, 13, 12 and 4 before grafts were made from hooded donors. After 28 days, the grafts were still functioning in 7–10 of the pretreated recipients as compared with 7–27 of untreated but otherwise similar recipients for which records were available at the time. Afterwards, pretreatment was by a single intraperitoneal injection equivalent to four pairs of ovaries, groups of ten pretreated recipients and ten untreated recipients being used for each test. The first variable examined was the time of treatment before grafting, intervals of 1, 3 and 7 days being chosen in the light of the work of Kaliss and Day[8] on tumour grafts. Suggestive results were obtained with the recipients treated 7 days before the grafts were made, and three replications of this experiment were therefore carried out. In each, more grafts took and many more persisted in pretreated than in untreated recipients. The final result was that the grafts became active in 20–39 of the untreated recipients and remained active for 28 days or more in 7–39, the corresponding figures for the pretreated recipients being 31–40 and 24–40. The difference at 28 days is highly significant ($p = 0{\cdot}001$) and leaves little doubt that the pretreatment had had a significant effect upon the survival of the graft. The effect may be prolonged as continued observation in the first two experiments showed that active grafts were present in 0–20 untreated and 9–20 treated recipients at three months after grafting. Further experiments suggest that freezing of the suspension is not necessary, except perhaps to prevent the formation of ancillary grafts on the peritoneum. Suspensions subjected to ultrasonic vibrations are equally or even more effective. Work with other tissues and on component parts of the suspension is in progress, with the view of applying the technique to the extension and development of orthotopic ovarian grafting and the study of oocyte survival in frozen and stored tissue.

My thanks are due to Dr. J. H. Humphrey for much helpful information and advice, to Miss M. V. Mussett for the statistical analysis of the results, and to Miss M. P. Moylan for technical assistance.

Corneal Homografts

IT has now been established that homografts of cornea and cartilage behave quite differently from skin homografts and can survive for long periods. The clinical success of the corneal graft has been known since 1878 [1], and there is ample evidence from histological and autoradiographic studies of experimental corneal homografts to confirm that they remain viable long after homografts of tissues such as skin are destroyed by the host tissues[2–4].

We have now examined more than a hundred corneal homografts implanted subcutaneously into guinea pigs and have found preservation of the corneal epithelium after two months, while at the end of three months the ground-substance survives unvascularized.

Experiments have recently been completed to test for any host sensitization. In fifteen guinea pigs a corneal homograft was inserted into the left lateral body wall, and four weeks later a second corneal homograft from the same donor was placed in a corresponding position on the right side of each animal and the grafts left in position for a further two weeks. Twenty-four hours before removal of the grafts the host animal was given 5 mc. of sulphur-

35 sulphate. First and second set homografts were then removed, sectioned, stained and prepared for autoradiography.

There was preservation of the corneal epithelium of both first and second sets of grafts, and no apparent difference in the uptake of sulphur-35 sulphate by the ground-substance compared to autoradiographs of 'control' cornea from host animal, indicating a normally functioning tissue. Thus there is no evidence of the sensitization of the host to corneal tissue which would be expected if the first grafts had produced a host-immune reaction.

It is our opinion that in both cartilage and cornea the mucopolysaccharides of the intercellular material are the specific substances responsible for the acceptance of these grafts by the host animal. A full account of these results will be reported elsewhere.

Sialoadenectomy and the Metabolism of Calcium-45 in Bone and Soft Tissues of the Mouse

IT has been reported that there are substances extractable from salivary glands which, when administered to animals, lead to a reduction of the plasma calcium[1]. Further observations[2] indicated the extracted proteins to be capable of promoting the calcification of hard tissues. Sialoadenectomy has been reported to reduce markedly the total ash, calcium, magnesium and phosphorus of the bones of the rat[3]. Our observation[4] that sialoadenectomized rats and mice exhibited reduced rates of growth, plus the study of Mari[5], who observed an increased growth-rate in chick embryo femurs, suggested that we study the metabolism of calcium in intact and sialoadenectomized animals.

The animals used in these studies were adult males, 25 ± 3 gm. The sialoadenectomized animals were prepared and treated as described previously[6]. There were not less than 8 and not more than 12 mice in each experimental group. Calcium-45 chloride was administered intraperitoneally dissolved in isotonic saline. The radiation dose was maintained at 5 μc. per 25 gm. body-weight. The specific activity of the calcium-45 was 102 μc. per mgm. calcium. The calcium-45 content of the tissues was determined 2 hr. after administration of the isotope. Animals were killed by exsanguination, tissues removed, washed with cold saline, blotted dry and samples therefrom weighed and digested by wet oxidation[7]. The clear digests were diluted to convenient volumes and aliquots plated on to tared glass planchets and dried. Radioassay was performed with the aid of a gas-flow counter and counting was extended in time to give a 2 per cent statistical error. Conventional corrections for decay, dilution and self-absorption were applied as required.

The calcium-45 incorporation into bone and nearly all the soft tissues (thymus and lung excepted) was greater in the sialoadenectomized mice (Table 1). The bones (femurs) of the sialoadenectomized animals concentrated calcium-45 1·64 times more than did the intact controls, liver 1·44, kidney 1·20, brain 1·31, spleen 1·36, heart 1·30, lung 0·87, muscle 1·23, thymus 0·68, thyroid 1·39, adrenal 1·21, testes 1·56. The generally higher uptake of calcium by the sialoadenectomized mice suggested that the animals were depleted in calcium and that a calcium-balance study was desirable A three-day balance was performed on intact and sialoadenectomized mice using a finely powdered commercial grain ration, the calcium content of which we found by analysis to be 1·02 per cent. The results of the balance study (Table 2) show a reduced intake by the sialoadenectomized mice, a higher fæcal output and a lower urinary output, indicative of decreased absorption of dietary calcium. The reduced urinary excretion was investigated with calcium-45 and found to be 38 per cent of control values in a 24-hr. test. The balance study on dietary calcium indicated a 52 per cent difference, but this discrepancy is obviously due to the different routes of administration and consequently the degree of absorption.

Table 1. DISTRIBUTION OF CALCIUM-45 IN INTACT AND SIALOADENECTOMIZED MOUSE TISSUES 2 HR. AFTER INJECTION OF 5 μc. ^{45}CaCl$_2$
(Results expressed as counts/min. per mgm. of tissue)

	Group	
	Intact	Sialoadenectomized
Femur	675 ± 35*	1,106 ± 111

Liver	9·8 ± 1·1	14·1 ± 1·5

* Standard error of the mean.

In a single experiment, the 2-hr. uptake of strontium-89 was measured in intact and sialoadenectomized animals. The activity of the sialoadenectomized animal femurs was 175 per cent of control values. This we feel to be indicative of a mineral depletion resulting from the sialoadenectomy. It is interesting to note that the difference in calcium-45 uptake and strontium-89 uptake between intact and sialoadenectomized animals is of the same order of magnitude.

The interpretation of the observed differences in the calcium metabolism of sialoadenectomized animals is at present difficult to explain. The results presented here suggest interference with the absorption of calcium from the digestive tract. Also, previous studies indicated that sialoadenectomy inhibits thyroid activity in a manner involving the hypophysis[8]. Since the thyroid has been shown to be related to calcium absorption, and further, since the growth hormone of the hypophysis regulates the function of new bone tissue and also influences the digestive secretions[9], these current observations indicate that the physiological function of the salivary glands needs re-evaluation.

Table 2. CALCIUM BALANCE ON SIALOADENECTOMIZED AND INTACT MICE, *ad lib.* FEEDING
(Results expressed as mgm.kgm./24 hr.)

Some Metabolic Effects of Poliomyelitis Virus on Tissue Culture

A DESIRABLE experimental condition for the study of metabolic effects of viruses on living organisms is that all or nearly all the cells be infected and that they be infected approximately simultaneously so that any metabolic changes can reasonably be expected to take place at about the same time throughout the cell population. This condition can readily be achieved with bacteriophages and their hosts, and a great deal of valuable work has been done with this system[1,2]. It has been virtually impossible to approximate to the necessary conditions with animal viruses and their intact hosts. The closest approximation has been achieved in the work with eggs; but complications introduced by host influences must be considered. As a result, our knowledge of metabolic changes induced in animal cells by animal viruses is limited. With the present emergence of tissue-culture techniques as an almost standardized procedure and the availability of animal virus suspensions of high titre, it has become feasible to undertake quantitative metabolic studies with animal viruses, and to relate any observed effects with virus growth. The present preliminary report is a summary of work on the effect of Type III poliomyelitis virus (Saukett strain) on some aspects of the metabolism of monkey kidney tissue culture; specifically, the effects of the virus on glycolysis and on the uptake by the tissue of glycine-2-carbon-14.

Two-ounce or thirty-two-ounce bottles of trypsinized monkey kidney tissue culture with lactalbumin hydrolysate or 199 medium were used in all the experiments[3]. Type III poliomyelitis virus (Saukett strain) was the infecting agent. It had a titre of about $10^{8.0}$ 50 per cent tissue culture infectious doses per 0·5 ml. The design of the experiments was as follows: the growth medium was poured off a number of two-ounce or thirty-two-ounce bottles of tissue culture, the cells washed with new medium, and new medium was added to the bottles. To half the bottles enough virus, in tissue culture medium, was added so that approximately seventy 50 per cent tissue culture infectious doses were present for each cell in the bottle. The other half of the bottles served as controls. Instead of the virus suspension, they received an equal volume of growth medium previously exposed to metabolizing cells. At intervals, beginning at the time of addition of the virus and continuing for 22 hr., groups of control bottles and groups of infected bottles were removed for analysis. Thirty minutes before a given batch of bottles were scheduled to be removed for analysis, glycine-2-carbon-14 was added. When the bottles were removed (after 30 min. of contact with the glycine-2-carbon-14) the fluids were poured off and analysed for lactic acid by the method of Barker and Summerson[4]. The cells were washed repeatedly with saline, scraped off the bottles, and the weight of the cells, as well as their radioactivity, determined. The quantity of lactic acid found at the start of each interval was subtracted from the amount of lactic acid found at the end of that interval, so that, in Fig. 1, the effect of virus on the rate of formation of lactic acid is presented, rather than the cumulative amount found.

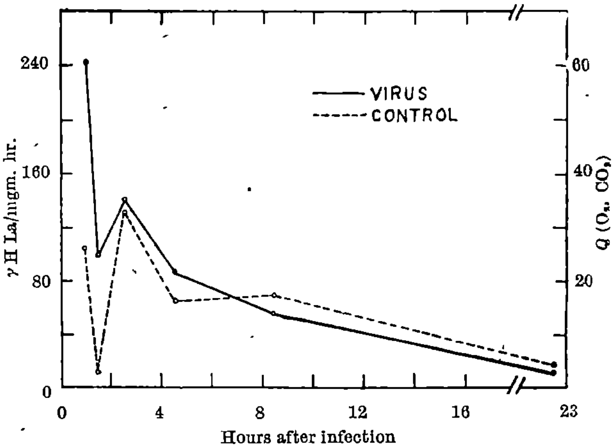

Fig. 1. Effect of poliomyelitis virus on aerobic glycolysis of monkey kidney tissue culture

It will be seen that within $\frac{1}{2}$ hr. (in some experiments 1 hr.) there was a marked increase in the rate of lactic acid production in the infected cells as compared to the control cells. This increased rate continued during 6–12 hr., by which time the glycolytic rate in the infected cells had generally fallen to a level below that of the controls. In other experiments the virus was partially purified by a few cycles of differential centrifugation in order to reduce the likelihood that some constituent of the infecting medium other than virus was responsible for the observed effect. That the stimulation of glycolysis was actually due to the virus is strongly suggested by the fact that such partially purified virus caused an effect similar to that shown in Fig. 1.

Two other cytopathogenic substances, thimerosal and diphtheria toxin, at concentrations of 10 μgm./ml. and 1·5 Lf. units/ml., respectively, were tested for effect on glycolytic rate of monkey kidney tissue culture. It was found that while the thimerosal had no effect, the diphtheria toxin caused a greater increase in the glycolytic rate than did the virus, followed by a fairly rapid decline.

It might be noted that the glycolytic rate of normal monkey kidney tissue culture is extremely high. Such rates have generally been reported only for highly malignant tumour cells[5].

The effect of infection on the rate of uptake of the radioactivity of glycine-2-carbon-14 is shown in Fig. 2. The datum at each point represents the counts per minute of carbon-14 taken up in the preceding 30 min. by each milligram dry weight of tissue.

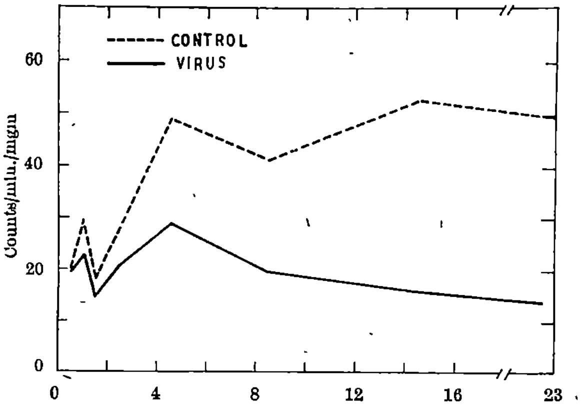

Fig. 2. Effect of poliomyelitis virus on uptake of glycine-2-carbon-14 by monkey kidney tissue culture

It will be seen that infection causes a significant and early depression of the rate of uptake of radioactivity. The partially purified virus described in the section on lactic acid produced the same effect. The other toxic agents tested (thimerosal and diphtheria toxin) both caused more rapid and marked depression of radioactivity uptake than did the virus, the uptake of the tissue after two hours of exposure to thimerosal being only 7 per cent of that of the controls.

In summary, exposure of monkey kidney tissue to high concentrations of Type III poliomyelitis virus leads, within an hour or less, to a stimulation of aerobic glycolysis and to a decrease in the rate of uptake of radioactivity from glycine-2-carbon-14. Two other cytopathogenic substances, thimerosal and diphtheria toxin, exert effects that have some qualitative similarities, as well as differences from those of the virus; but the markedly different quantitative aspects suggest the possibility of a difference in mechanism of action. A more detailed report will be published later.

Action of the Hypophysis and of Dietary Protein on the Calcifying Tissues

IT is well known that protein deficiency causes considerable interference with endochondral calcification in growing rats, the growth of the epiphyseal plate and the formation of calcified trabeculæ ceasing, the face of the plate being finally sealed off with bone[1,2]. Similar changes are seen after hypophysectomy[3]. In the case of the continually erupting incisor tooth of the rat, protein or amino-acid deficiency causes very slight changes, chiefly an interference with the calcification of the dentin[4-6]. Hypophysectomy induces very marked changes in the incisor, the chief defect being caused by the processes of eruption and incremental growth being differently affected. As a result, there is a relative overgrowth of dentin, the pulp cavity becomes smaller and later the formative end of the tooth is thrown into folds. Other degenerative changes also occur[7,8].

In recent experiments[9,10], young growing rats were put on diets containing 9·3 per cent protein, for from 10 to 117 days. Very marked abnormalities were seen in the epiphyses of the long bones, similar to those described above; they were completely prevented by raising the protein content of the diet to 18·8 per cent. The incisor teeth of the rats on the low-protein diet showed no significant changes in shape or rate of dentin formation or size of the pulp cavity, nor were the effects described by Hunter[4] and Bavetta *et al.*[5,6] seen, probably because the dietary conditions were less stringent than in their experiments.

The literature is not clear about the part the hypophysis plays in the changes which occur in bone during protein deficiency. Follis[1] says the question has not "been satisfactorily answered". Frandsen *et al.*[2] do not think the results in their experiments are due to reduced action of the gland. In view of the striking effects that occur in the teeth after hypophysectomy and the complete absence of such changes in protein deficiency, I conclude that the fundamental actions of the hypophysis and of protein on the hard tissues must be completely unconnected.

Synthesis of Phosphocreatine by Enzymes from Heart and Skeletal Muscle

THE transfer of phosphate from high-energy phosphate compounds of glycolytic origin (such as phosphoglycerylphosphate and enol-phosphopyruvate) to creatine has been considered possible only through the adenylic nucleotides[1]. Direct proof of this has been given so far only for enol-phosphopyruvate[2]. In the case of the acyl-phosphate, examination of thermodynamic data[3] shows that a direct transphosphorylation from phosphoglyceryl phosphate to creatine is possible and that an equilibrium constant of about 10 might be expected.

In order to test this possibility, a reconstituted system capable of phosphoglyceryl-phosphate genera-

Table 1. Final concentration of the components in a volume of 2 ml.: 0·025 *M* potassium phosphate buffer, *p*H 7·4; 0 0025 *M* magnesium chloride; 0·01 *M* potassium pyruvate; 0·0005 *M* diphosphopyridine nucleotide; 0·05 *M* creatine; aldolase 0·5 mgm. protein/ml.; triosephosphate dehydrogenase 0·5 mgm. protein/ml.; lactic dehydrogenase, 0·25 mgm. protein/ml.; 0·0025 *M* fructose diphosphate ('direct' activity) or 0·01 *M* adenosine triphosphate (adenosine triphosphate–creatine phosphokinase).
Heart or skeletal muscle enzymes were assayed at levels between 0·3 and 4 mgm. protein/ml. Results are expressed in μmoles of phosphocreatine synthesized per mgm. of protein in 20 min. at 37°

	(*a*) 0 and 25 per cent of saturation	0·09	0 01		
	(*b*) 25 and 50 per cent of saturation	1·7	1·9		
	(*c*) 50 and 75 per cent of saturation	3·1	1·3		
	(*d*) 75 and 85 per cent of saturation	1	10 4		
	(*a*) 0 and 45 per cent of saturation	0·3	0		
	(*b*) 45 and 65 per cent of saturation	2 4	1·2		
	(*c*) 65 and 85 per cent of saturation	1	11 5		

tion was assayed for phosphocreatine synthesis in the presence of enzyme preparations obtained, on one hand, from skeletal muscle, where glycolysis is an important source of high-energy phosphate compounds, and on the other, from heart muscle, which is known to depend mainly on aerobic phosphorylation mediated by the adenylic nucleotides. Preparations of the transphosphorylating enzymes were obtained from extracts of rat heart or skeletal muscle by repeated fractionation with ammonium sulphate; nucleotides were removed by treatment with charcoal and 'Dowex 1'.

In experiments designed to detect in these preparations the existence of a system capable of directly transferring phosphate from phosphoglyceryl phosphate to creatine, the acyl phosphate was generated in the same tube from fructose diphosphate by means of aldolase, triose phosphate dehydrogenase and lactic dehydrogenase in the presence of diphosphopyridine nucleotide, orthophosphate, magnesium and pyruvate. These three enzymes were also treated with charcoal. Commercial fructose diphosphate was purified by barium precipitation and charcoal treatment. Diphosphopyridine nucleotide was purified by anion-exchange chromatography. Hexokinase from the Sigma Chemical Co. was further purified with alumina gel and charcoal. Spectrophotometric analysis of the mixture for adenine nucleotides gave negative results.

The appearance of phosphocreatine after incubation for 20 min. at 37° C. was measured. The initial values were always zero.

Table 1 shows that the synthesis of phosphocreatine with fructose diphosphate as substrate occurs in the presence of enzyme preparations from skeletal muscle without adding any adenylic nucleotides. (This reaction will be referred to as 'direct' reaction.) Preparations from heart muscle, on the contrary, are devoid of such activity, although they are quite able to synthesize phosphocreatine if offered adenosine triphosphate. The possible existence of two separate enzymes for these two activities in skeletal muscle is suggested by the different patterns of fractionation (Table 1*B*).

Absence of catalytic amounts of adenosine diphosphate from the system was shown by using glucose in presence of hexokinase as phosphate acceptor instead of creatine. No inorganic phosphate is esterified in the absence of added adenosine diphosphate; a concentration of 10^{-5} *M* nucleotide allows an esterification of 1·5 μmoles in 20 min.

Synthesis of phosphocreatine from fructose diphosphate is enhanced from 3·9 to 4·8 μmoles in 20 min. by the presence of 2 × 10^{-5} *M* adenosine diphosphate, whereas 10^{-6} *M* nucleotide is ineffective. Since the skeletal muscle preparations contain the enzymes responsible for the transformation of 3-phosphoglycerate to enol-phosphopyruvate, this stimulation may be due to transfer of phosphate from the latter compound through adenosine diphosphate to creatine. Proof of this is the fact that 3-phosphoglycerate may be utilized for the synthesis of phosphocreatine only if 10^{-4} *M* adenosine diphosphate is present. This absolute requirement for the nucleotide may also be taken as a proof of its absence from our system.

The absence of adenine nucleotides is also confirmed by the fact that hexokinase does not inhibit the 'direct' synthesis of phosphocreatine. If this process is stimulated by 10^{-4} *M* adenosine diphosphate, a strong inhibition can be achieved by hexokinase. This would again point to a pathway where there is no competition for adenylic nucleotides.

Table 2 may also be interpreted in a similar way. Adenosine triphosphatase does not interfere with the 'direct' pathway of phosphocreatine synthesis, whereas it completely masks the adenosine triphosphate–creatine phosphokinase, the activity of which appears only after removing the adenosine triphosphatase.

Table 2. Results, conditions and concentrations for phosphocreatine synthesis as in Table 1. Adenosine triphosphatase assayed under the same conditions, but omitting creatine and using 0 05 *M* adenosine triphosphate. Activity is expressed in μmoles of 7-min. phosphorus hydrolysed per mgm. of protein in 20 min. at 37°

Type of enzyme preparation	'Direct' activity	Adenosine triphosphate–creatine phosphokinase activity	Adenosine triphosphatase
Fraction from skeletal muscle precipitated with ammonium sulphate at 40 per cent saturation	0·91	0 02	4·5
Same fraction after treatment with 0·25 volume of calcium phosphate gel of 1·8 per cent dry weight (ref. 5)	1·8	0·04	4 3
Same fraction after treatment with 0·5 volume of calcium phosphate gel	6·4	2	0

Preparation of phosphoglyceryl phosphate[6] enabled us to obtain a more direct proof of phosphate transfer from the acyl phosphate to creatine. This reaction occurs in the presence of enzyme from skeletal muscle, requires magnesium and is not inhibited by hexokinase. Since the acyl phosphate had also been treated with charcoal, these results strongly suggest the existence of a mechanism not linked to the adenylic nucleotides.

This investigation was partially supported by a grant from the Rockefeller Foundation. We are indebted to Dr. George Hodgson for helpful discussion.

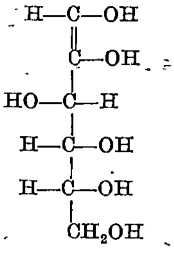
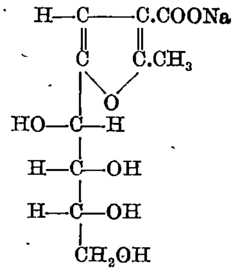
Occurrence of 1:2 Dienol Glucose in Normal Blood: its Reaction with Alloxan and Chromatographic Identification

IN 1922 when Winter and Smith[1] published results indicating for the first time that glucose in the blood of normal animals and men occurs in a form which is different from the ordinary α- and β-glucose. Lungsgaard and Holboll[2], from their polarimetric studies of blood, also concluded that a new form of glucose always occurs in the blood of normal human beings, but they could not say anything about its chemical nature or physiological significance.



(I)

1 : 2 Dienol glucose



(II)

Condensation product of glucose and acetoacetate

It has been reported by West and Rinehart[3] that one molecule of an endiol compound reacts with two molecules of ninhydrin to give rise to hydrindantin ($C_{18}H_{10}O_6$), and it has recently been shown by us[4] that 1 : 2 dienol glucose (I), which is formed on hydrolysing the condensation product of glucose and acetoacetate (2-tetrahydroxy butyl 5-methyl 4-carbethoxy furan) (II), reacts with alloxan, which shows a structural resemblance with ninhydrin, at pH 7·2, and gives rise to the non-diabetogenic alloxanic acid.

It was thought that normal blood might also contain some such active principle, which might be able to combine with a small amount of alloxan in order to transform it to a non-diabetogenic product before it could reach the pancreas to bring about damage to the β-cells, and that diabetes might occur only when this reactive substance was completely depleted. This prompted us to examine normal blood to see if it also contains glucose in the endiol form which can react with alloxan, and to find out whether diabetic animals show the absence of such glucose in their blood.

For this, 2 c.c. of blood each from normal rabbits, deproteinized with 10 per cent trichloroacetic acid and brought to pH 7·2, was allowed to react with alloxan (4 mol. proportion per 1 mol. sugar) at 30° C. and the reducing sugar was estimated periodically by Hagedorn and Jensen's method[5] (Table 1).

Blood samples from a number of rabbits (six) injected with a diabetogenic dose of alloxan (collected 15 min. after the injection) were treated as above with alloxan; none gave any indication of reaction, thus showing that glucose occurring in more reactive form might have already combined with alloxan in the animal system.

Although the other reducing substances such as ascorbic acid and reduced glutathione are known to combine with alloxan, none of these has been found to interfere with the estimation of sugar by Hagedorn and Jensen's method. Hence the diminution of the reducing sugar as shown in Table 1 is due to its combination with alloxan.

It should be pointed out here that although the blood samples collected from different normal persons and from normal rabbits showed the presence of reactive glucose, ordinary glucose D never showed any change in its value when treated with alloxan under identical conditions. Nath *et al.*[6] have also observed that the hydrolysed condensation product combines with ninhydrin to give rise to a coloured compound, hydrindantin, thus giving additional

Table 1. PERCENTAGE OF BLOOD SUGAR REACTED WITH ALLOXAN (*in vitro*)

(*B*) Normal human subjects

Case No.	I	II	III	IV	V	IV	VII	VIII	Average value and mean deviation
Per cent glucose reacted in ¼ hr	8·0	2·3	13·0	8·5	13·3	3·2	6·2	2·0	6·4 ± 4·3
Per cent glucose reacted in ½ hr.	10·2	4·0	26·7	8·5	13·3	5·0	8·0	6·2	10·2 ± 6·8

No further change in glucose was observed after ½ hr.

evidence for the formation of 1 : 2 dienol glucose from the condensation product. Further, glucose in aqueous solution, during incubation at *p*H 7·2 for 24 hr., has been known to be partially transformed to 1 : 2 dienol glucose[7], and this incubated glucose has also been found to react with alloxan.

The results in Table 1 also account for the conversion of alloxan to alloxanic acid in the blood, when injected into normal animals, as observed by Seligson and Seligson[8]. It was shown by Meyer[9] that all endiols take up bromine instantaneously with intermediate formation of dibromoenol, which forms labile bromoketones. These bromoketones can oxidize hydrogen iodide and liberate iodine. This test was found to be positive with all the three substances, namely, glucose incubated at *p*H 7·2, hydrolysed condensation product (after removal of the ethereal extract) and deproteinized blood (after removal of the ethereal extract), thus showing definitely that blood contains dienol compounds. Since one important dienol compound, ascorbic acid, is also known to be present in blood, attempts were made to see if any confirmatory evidence for the occurrence of any other dienol compound in the blood could be made available, and if so in what form.

The technique of circular paper chromatography as used by Giri and Rao[10] was followed. Chromatograms with glucose, ascorbic acid and hydrolysed condensation product as well as with blood deproteinized by trichloracetic acid were obtained in duplicate on Whatman filter paper No. 1 of 18·5 cm. diameter, fitted with a wick at the central hole in Petri dishes placed in a closed chamber with solvent mixture containing butanol/acetic acid/water (40 : 10 : 50), the top layer being used. A special reagent, specific for endiol compounds, was found for the development of the chromatograms. It has been shown by Feigl and Cardoso[11] that certain reducing agents, which are without effect in acid solutions towards molybdate ions or which are only slightly active, reduce the latter immediately when phosphate ions, which produce complex phosphomolybdate ions, are present. Although glucose cannot reduce this compound in the acid medium to molybdenum oxide or 'molybdenum blue', ascorbic acid, which is a dienol compound, can do so. Ammonium phosphomolybdate reagent has been found by us to be reduced by 1 : 2 dienol glucose and was therefore selected for developing the chromatogram. The procedure is as follows: the paper chromatogram is immersed in 20 per cent alcoholic phosphomolybdic acid, allowed to drain and dried in a current of cold air; it is then washed in a 20 per cent ammonium nitrate solution acidified with a few drops of nitric acid, washed with water and dried by hot air.

Triphenyl tetrazolium chloride, which is commonly used for developing chromatograms with reducing sugars and sugar derivatives, was also used to develop another set of chromatograms with all the reducing compounds used previously as well as deproteinized blood.

While comparing the bands on the chromatogram with ascorbic acid, hydrolysed condensation product and deproteinized blood developed by the special phosphomolybdate reagent, ascorbic acid shows a band with R_F 0·52 and the blood shows the presence of a new dienol compound having its R_F value as high as 0·92 and similar to that with 1 : 2 dienol glucose. Ordinary glucose does not show any band with this reagent. Human diabetic blood also does not show any development of colour with the phosphomolybdate reagent, thus showing the absence of any endiol glucose.

The chromatogram developed with triphenyl tetrazolium chloride has a band with R_F 0·92 corresponding to 1 : 2 dienol glucose, which is liberated from the condensation product of glucose and acetoacetate on acid hydrolysis. Ordinary glucose has a much lower R_F value, which is in the neighbourhood of 0·32, and that for ascorbic acid is 0·52. The multiple-spot chromatogram with deproteinized blood shows clearly that a large portion of the reducing sugar resolves itself in the same region as that shown by 1 : 2 dienol glucose. The circular bands for ordinary glucose and ascorbic acid were also developed.

It is thus evident that a portion of the glucose in the normal blood occurs in the reactive endiol form which can easily react with alloxan and has the R_F 0·92 (against 0·52 for ascorbic acid) on a circular paper chromatogram when developed with a special reagent for endiol compounds only.

Release of Adrenaline and of Noradrenaline from the Adrenal Gland of the Cat and the Subsequent Resynthesis of these Amines

SEVERAL workers[1] have shown that there are various ways of causing a release of sympathomimetic amines from the adrenal medulla, for example, splanchnic nerve stimulation, insulin and nicotine. Few, however, have studied the subsequent resynthesis of these amines. It was thought possible that such an investigation might help to reveal the route by which adrenaline is synthesized biologically. Thus a study of the cat adrenal glands depleted by acetylcholine, the natural mediator of the splanchnic nerve[2], has been made.

The adrenal glands of atropinized, adult cats were depleted of their amine content by repeated, intravenous doses of acetylcholine. In all experiments one gland of each animal was used as a control and the depleted gland was compared with it. Also, control experiments were performed. The adrenaline and noradrenaline content of the glands was determined biologically, using the cat blood pressure and the cat nictitating membrane as separate test preparations. The results were calculated by a formula devised by Bulbring[3]. A qualitative chromatographic analysis also was made, in order to determine whether any other catechol amines were present.

Using acetylcholine, it was found that there was a similar percentage loss of adrenaline and of noradrenaline and that this was irrespective of the degree of depletion. The range of depletion was 7·1–86·5 per

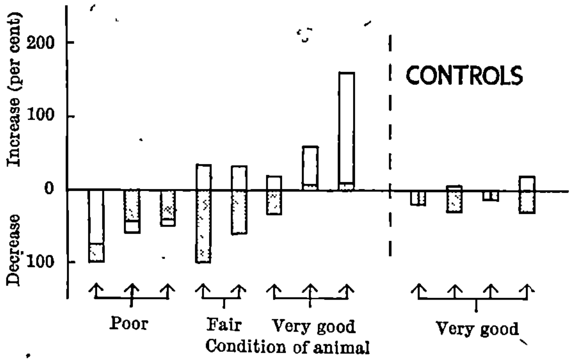

Fig. 1. Adrenaline and noradrenaline content of the second adrenal gland of the cat 2–3 days post-operatively. Adrenaline is shown by the stippled and noradrenaline by the white columns

cent. Correlating the amines lost from the depleted gland with the amines in the plasma obtained from the adrenal venous effluent, it was found that the percentages of noradrenaline in both the control gland and the depleted gland and in the plasma were the same. The total amount of amine in the plasma was equal to, or a little less than, the amines lost from the depleted gland. Hence there was no re-synthesis of the amines while the gland was being stimulated by the acetylcholine.

In an attempt to determine how long it would take for the depleted gland to replace the amine that it had lost, the animal was left on a warm operating table for as long as 17 hr. after the depletion of the glands. However, there was no increase in the amine content during that time, and if there was a gradual decline in the blood pressure, instead of the amine being replaced more was lost. This loss was prevented by the denervation of the gland; but, in spite of this, little or no resynthesis could be obtained. Thus in a further series of experiments, the animal was allowed to recover from the anæsthetic, following the depletion of both glands and the removal of one. After a period of several days the second gland was removed. It was found that 2–3 days post-operatively there was a small increase in the amine content, providing that the animal was in good condition (Fig. 1). After 6–7 days, unless the animal was in poor condition, when again there was a further loss of amine, there was a marked increase in the amine content. By this time, although the total amine had returned to its initial level, there was now an alteration in the proportion of adrenaline to noradrenaline present. Although the adrenaline content had increased by only a small amount, the noradrenaline content was many times its depleted level (Fig. 2). Thus it may be concluded that noradrenaline is synthesized at a much faster rate than adrenaline, under the conditions of these experiments, and it may be inferred that adrenaline is synthesized from noradrenaline.

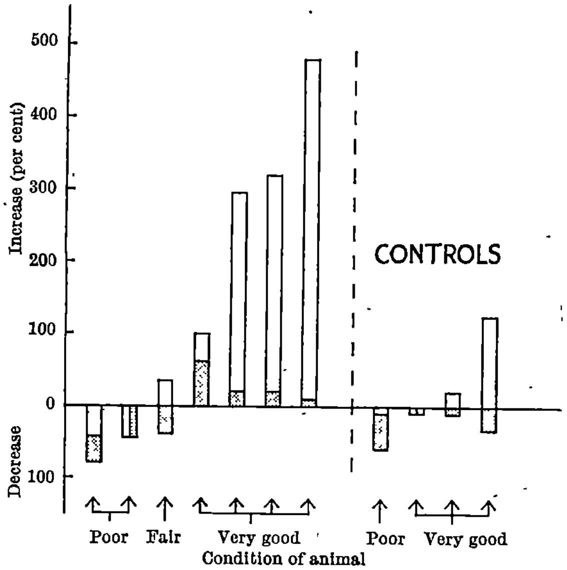

Fig. 2. Adrenaline and noradrenaline content of the second adrenal gland of the cat 6–7 days post-operatively. Adrenaline is shown by the stippled and noradrenaline by the white columns

Experiments are now in progress on the proportions of the two amines present in the gland after a re-synthesis period of one month. This work will be reported in detail elsewhere.

Hereditary Defects of Temperate Bacteriophage

SEVERAL mutations of temperate bacteriophages are known which can be carried by the prophage of the lysogenic cell but bring about almost complete failure to release infectious particles when the cells are exposed to radiation[1-4]. One such group is known to be transmissible through all parts of the life-cycle including extracellular phage[2]; among these are the defects *i*1 and *i*2 of the bacteriophage *lambda* carried by *Escherichia coli K*-12.

The phenotype of a double lysogen (a bacterium carrying two prophages) containing both a defective ($i = i1$ or $i2$) and a healthy (i^+) prophage is like that of a normal lysogen: the cell liberates healthy phage on induction. This suggests an analogy between the phage defects and the recessive lethals of higher organisms. If the analogy is valid, it would be expected that different loci would be involved in independently derived defective lysogens. We report here a single experiment upon recombination between *i*1 and *i*2 which demonstrates both the expected difference in the gene loci and a difference in the physiological consequences of the respective mutations to defective lysogeny.

To prove that the defects are not allelic, it is necessary to show that healthy phage can be derived by genetic recombination between *i*1 and *i*2. For this purpose, cultures of *lambda-i*1 or *lambda-i*2 lysogens were induced by small exposure to ultra-violet light. The cells almost all lysed 1½ hr. later, releasing a very small number, about 10^{-5} per cell, of i^+ phage and a rather larger number of i phage. Any remaining bacteria were killed by shaking the lysate with chloroform. The lysates were partially

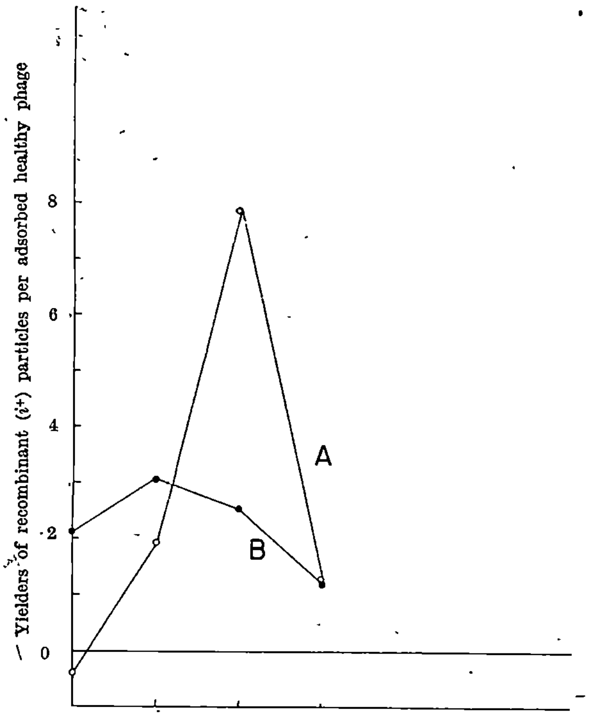

Fig. 1. Variation with time post-induction of the number of yielders of recombinant (i^+) particles per adsorbed healthy phage in infections of strain *C* 112 ($\lambda\, i2$) with $\lambda\, i1$ (curve *A*) and strain *C* 112 ($\lambda\, i1$) with $\lambda\, i2$ (curve *B*). The number of healthy phage yielders per adsorbed phage in homologous infections (*i*1 on *lambda-i*1 lysogens and *i*2 on *lambda-i*2 lysogens) was always less than 1 0 and this value is represented by the base line marked as 0

purified by differential centrifugation. A sample of phage from each lysate was now permitted to infect both a *lambda-i*1 and a *lambda-i*2 lysogen at various times, *t*, after these had been similarly induced. After allowing twenty minutes for phage adsorption, the induced infected cultures were assayed before lysis for yielders of infectious i^+ particles. After eliminating unadsorbed phage there are three sources of these particles in the induced infected cultures : (1) induced cells in which a reversion $i \rightarrow i^+$ has occurred ; (2) cells which have been infected by an i^+ phage present in the infecting lysate as a result of a reversion $i \rightarrow i^+$ in the culture from which it was made ; (3) in appropriate infections, cells in which a recombination between *i*1 and *i*2 has given rise to i^+ phage.

(1) and (2) were counted by separate assays of the uninfected induced culture and the infecting lysate. When *i*1 lysates infected induced *lambda-i*1 lysogens, or *i*2 lysates infected induced *lambda-i*2 lysogens, the total number of yielders of i^+ phage never significantly exceeded (1) + (2) at any time, *t*. Similarly, timed heterologous infections (*i*1 on *lambda-i*2 lysogens and *i*2 on *lambda-i*1 lysogens) were also carried out and the fraction by which i^+ yielders exceeded (1) + (2) was plotted as a function of *t* (Fig. 1).
